TO
THE RIGHT
HONOURABLE
SIR EDWARD HERBERT,

KNIGHT OF THE BATH,

Lord Herbert of Castlelland,

and Baron of Cherbury.

SIR,

It is not the farre-fetcht pedegree of noble Ancestors, nor those Honours your Lordship deservedly possesse, that make mee crave your Patronage to this my Labour; but it is that Heroick minde, enriched with the choice endowments of Nature and Art, and that earnest affection wherewith your Honour entertaines all Sciences, Arts, and Artists, with that exquisite Judgment which sees into the inner man, which embolden and incite me to sue for your Honours assistance, in protecting the fame of him, who by your many favours is made yours. I know the seeming and selfe-pleasing Wisedome of our times, consists much in cavilling, and unjustly carping at all things that see light, and that there are many who earnestly hunt after the publike fame of Learning and Judgement, by this easily trod, and despicable path, which notwithstanding they tread with as much confidence as folly; for that oft-times which they vainely and unjustly brand with opprobrie, out-lives their Fate, and flourisheth when it is forgot that ever any such as they had being.

I know your Lordships disposition to be farre dissenting from those men, and that you rather endeavour to build up the fame of your learning and Judgement upon a strong laid foundation of your owne, than *Herostatus* like, by pulling downe any howsoever faire built fabricke of another. I heartily wish that your Honour could propagate this good, and that all Detractors might be turned into Actors, and then I know it would much mitigate their rigour in censuring others,
C when

The Epistle Dedicatory.

when as they themselves were also exposed unto the same Hazard.

I thinke it impertinent to acquaint your Honour with the Nature of the Worke, my Paines in translating, or the Benefit that may ensue thereon, for that I know your Honour ignorant of nothing in this kind; neither doubt I of your favourable acceptance of the good-will of him, that thinkes himselfe much honoured by being

Yours,

THOMAS JOHNSON.

To The Reader,

I Have here for the publike good taken paines to subject my selfe to common censure, the which I doubt not but to finde as various as the faces of the Censurers; but I expect no thanks, nor hunt after other praise, than that I have laboured for my Countries good, if that deserve any. I feare not Calumniation (though sure to heare of it) and therefore I will not Apologize, but informe thee of some things concerning the Author his work, and the reason that induced me to the translation thereof, with some few things besides. For the Author, who was principall Surgeon to two or three Kings of France, hee was a man well versed in the writings of the antient and moderne Physitians, and Surgeons, as you may evidently finde by sundry places alledged in his workes. For his experience, or practice (the chiefe helpe to attaine the highest perfection in this Art) it was wonderfull great, as you may collect by his voyages recorded in the last part of this work; as also by that which *James Guillemeau*, Surgeon to the French King, a man both learned and judicious in his profession, averres, speaking of his owne education and progresse in the Art of Surgery. I so laid (*saith hee) the first foundation of this Art in the Hospitall of *Paris*, being, as it were, an ample Theater of wounds and diseases of all kindes, that for two whole yeares, during which time I was there conversant, nothing was consulted of, nothing performed, the Physitians, and Surgeons being present, whereof I was not an Auditor or Actor. There flourished at these times, and yet doth, *Ambrose Parey*, principall Surgeon to the most Christian King, the Author of this great worke, most renowned for the gracious favour of Kings, Princes and Nobles towards him, for his Authoritie amongst his equals, for his Chirurgical operations amongst all men. Therefore I earnestly endeavoured to be received into his family, as unto another *Machaon*, or *Podalirius*: once admitted, I so by all dutifullnesse and due respect acquired his favour, that he, unlesse I were present and assisting, did nothing (such is his naturall gentleness and curtesie to all such as are studious of the Art) at home or abroad, in the field, in the tents, or lastly in this famous Citie of *Paris*, about the bodies of Dukes, Noblemen, or Citizens, in whose cure, he by the ardent desire of them all, had still the prime place.

*In his Epistle prefixed before the Latine edition of this Author.

Now for this worke, heare what this same man in the same place affirmeth further: I not content with these meanes, which may seeme sufficient, and too much, as desirous to satisfie my long thirst, determined to try whether I could draw, or borrow any thing from strangers, which our men wanted, to the fuller knowledge of Surgery. To this purpose I travailed over Germany, and then for foure years space I followed the Spanish Armie in the Low-countries; whereas I did not onely carefully cure the wounded Souldier, but also heedfully and curiously observe what way of curing the renowned Italian, Germane, and Spanish Surgeons observed, who together with me were imployed in the Hospitall, for the healing of the wounded and sicke. I observed them all to take no other course than that which is here delivered by *Parey*. Such as did not understand French, got some pieces of this worke for large rewards, turned into Latine, or such Languages as they understood, which they kept charily, and made great store of; and they esteemed, admired, and embraced this worke alone, above all other workes of Surgery, &c. Our Author also himselfe, not out of a vain-glorious ostentation, but a minde conscious of the truth of his assertion, affirms thus much of this his worke. I have (saith hee) so certainly toucht the marke whereat I aimed, that Antiquity may seeme to have nothing wherein it may exceed us, besides the glory of invention, nor posterity any thing left, but a certaine small hope to adde some things, as it is easie to adde to former inventions. Thus much concerning our Authour, and the excellency of his worke.

Now come I to my translation, the which, as desiring more a publike good, than private praise, I have performed plainly and honestly, laboring to fit it to the capacity of the meanest Artift; for these are they to whom I chiefly commend this work, and from whom I expect acceptance. I being by the earnest perswasions of some of this profession, chiefly, and almost

To the Reader.

most wholly perswaded and incited to take this paines, who knowing the disability of understanding this Author in Latine or French, in many of the weaker members of the large body of their profession, dispersed over this Kingdome, and the rest of his Majesties Dominions, whose good, and encrease in knowledge may be wisht, that so they may be the better enabled to doe good to such as shall implore their aide in their profession.

There are some (I know) will blame me for Englishing this worke, as laying open the mysteries of a worthy Art, to the unworthy view of the vulgar. To such I could answer as * *Aristotle* did to *Alexander*: but for the present I will give them these, which I thinke may satisfie any but the purposely malicious: the first is drawne from the goodnesse of the thing, as intended for those that want such guides to direct them in their Art; for it is commonly granted, that, *Bonum quo communius eo melius*. Secondly, it hath beene the custome of most Writers in all Ages and Countries thus to doe: *Hippocrates*, *Galen*, and the other Greeks, writ in their mother tongue the mysteries of their Art: thus did *Celsus*, *Serenus*, and others in Latine: *Mesue*, *Avicen*, *Serapio*, and others, in Arabicke; as also, to goe no further, our Author writ this worke in his native French, and learned men have done the like in this, and all other Arts. And it is a great hinderance to us in these daies, that we must bee forced to learne to understand two or three tongues, before wee can learne any science, whereas the Antients learned and taught theirs in their mother tongue: so that they spent a great deale lesse time about words, and more upon the study of that Art or Science they intended to learne and follow. Thirdly, I must tell you, that, *Ex libris nemo evasit Artifex*, No man becomes a workeman by booke: so that unlesse they have had some insight in the Art, and be in some sort acquainted both with the termes of Art, as also with the knowledge and use of the instruments theretobelonging, if by reading this, or any other booke of the like nature they become Surgeons, I must needs liken them (as *Galen* doth another sort of men) * To Pilots by booke onely: to whose care, I thinke, none of us would commit his safety at Sea, nor any if wise, will commit themselves to these at land, or sea either, unlesse wholly destitute of other.

The other things whereof I must also give you notice, are these. The figures in the Anatomy are not the same used by my Author (whose were according to those of *Vesalins*) but according to those of *Bauline*, which were used in the worke of Dr. *Crooke*; and these indeed are the better and more complete. Also Page 807. I thought it better to give the true figure of the Helmet floured Aconite, mentioned out of *Pliny*, than to reserve the faiged picture of *Matthiolus*, which in our Author was encreased with the further fiction of a Helmet. I have in some few places in the margent, which you shall find marked with a star, put short annotations, for the better illustration of that which is obscure, &c. I have also in the Text to the same purpose, here and there put two or three words, contained in these limits [], which I finde here and there turned into a plaine Parenthesis, especially toward the latter end of the booke, but the matter is not great. Further, I must acquaint you that the Apologie and Voyages, being the last part of this worke, and not in the Latine, but French editions, were translated into English out of French by *George Baker*, a Surgeon of this City, since that time, as I heare, dead beyond the Seas.

This is all, Courteous Reader, that I have thought necessary to acquaint thee withall concerning this, which I would desire thee to take with the same minde that it is presented to thee, by him that wisheth thee all happinesse,

THOMAS JOHNSON.

THE
A V T H O R S
EPISTLE DEDICATORIE
To Henry the third, the most Christian
King of France and Poland.

Even as (most Christian King) we see the members of man's body by a friendly consent are alwayes busied, and stand ready to performe those functions for which they are appointed by nature, for the preservation of the whole, of which they are parts: so it is convenient that we, which are, as it were, Citizens of this earthly Common-Weale should be diligent in the following of that calling which (by Gods appointment) we have once taken upon us: and content with our present estate, not cowed away with rashness and envy, desire different and divers things whereof we have no knowledge. He which doth otherwise, perverts and defile the sacred confusion the order and beauty on which this Universe consisteth. Wherefore when I considered with my selfe, that I was a member of this great Mundane body, and that not altogether unprofitable, I endeavored earnestly, that all men should be acquainted with my doings, and that it might be knowne how much I could profit thereby. For God is my witness, and all good men know that I have now labored fifty Yeares with all care and paines in the illustration and amplification of Chirurgery, and that I have so certainly touched the mark whereat I aimed, that Antiquity may seeme to have nothing wherein it may exceed us, beside the glory of invention, nor posterity any thing left but a certaine small hope to adde some things, as it becometh to adde to former inventions. In performance whereof, I have beene so prodigall of my selfe, my watchings, faculties and meanes, that I spared neither time, labour, nor cost, whereby I might satisfie and accomplish my own desires, this my great work, and the desires of the studious. Neither may we doubt but their studies would at the length waxe cold if they only furnished with the Theoricke and Precepts of Schooles, and that with much labour should see no manuell operation, nor manifest way of performing the Arts For which cause I seeking the praise and profit of the French Nation, even with the hinderance of my particular estate, have endeavored to illustrate and increase Chirurgerie hitherto obscure either by the infelicity of the

The Authors Epistle Dedicatory.

former ages or the envy of the Professors; and not onely with precepts and rules, but being a lover of carved workes I beautified it with good formes, or graven figures and apt delinuations, in which whosoever shall attentively looke shall finde five hundred anatomicall, or organicall figures belonging to the Arte, (if they be reckoned particularly). To every of these I have given their names and shewed their use, least they should seeme to have beene put in vainly for ostentation or delight. But although there be few men of this profession which can bring so much authority to their writings either with reason, or experience as I can; notwithstanding I have not beene so arrogant, but intending to publish my worke, I first communicated it with men the most excellent in the Arte of Physicke, who gave me greater encouragement to perfect and publish it, that it might be in common use: professing they wished nothing more, than that it might be turned into Latine, so by which means it should be knowne to forraigne Nations, that there is no kind of Learning which is not delivered with great dexterity of wit in this kingdome over which you rule. And thus much I dare boldly affirme, that there is scarce any, be he never so stately or supercilious, but that he may here find something which may delight him, and by which he may better his knowledge. Therefore I doubted not to consecrate this booke unto your Majestie both as a Patterne and treasury of my labours as well in respect of my duty, who am yours by nature and education, as that I might manifest to all, your Highnes exceeding bounty towards me, in placing me (having heretofore enjoyed the office of principall Chirurgion under 3 Kings your Majesties predecessors) in the same dignity, and that of your owne accord. And moreover I did conjecture that it would fall out, as now it doth, that this my worke caried through the world by the fame of your Majestie name, should neither seare the face nor veile of any, supported by the favour and Majestie of a most invincible Monarch and most excellent and renowned Prince. Neither did King Charles the ninth of happy memory, incited by the relation of the most gracious Queene his Mother, refuse to reade it, being he understood it proceeded from him, who having happily passed all his time in private and publick employments, and conversed with all men of all sorts, was judged most worthy to obtaine this favour, as to have the front of this worke adorned and beautified with the splendor of his prefixed name. I encouraged by this hope, desired that my request should passe as by a certaine continuation and succession from a most powerfull, to a most invincible King; and doe wholly consecrate these my labours taken for my Countreyes good unto your sacred Majestie. God grant that your Majestie may have happy successe of all your enterprises abundantly added to Nestors yeares.

Paris. 8. Feb. Anno Dom. 1579.

Your most Christian Majesties
faithfull Servant

Andrese Parcy.

The Preface.

Most men derive the Original of Physicke from heaven; for those who hold the best opinion of the Creation of the world, affirme, the Elements being created and separated each from other, man being not as yet made; incontinently by the divine decree, all herbes and plants with infinite variety of floures, endewed with various sents, tastes, colours and formes, grew and sprung forth of the bowells of the Earth, enriched with so many and great vertues, that it may be thought a great offence to attribute to any other than the Deity, the benefit of so great a blessing so necessary for so many uses. Neither could Mans Capacity ever have attained to the knowledge of those things without the guidance of the divine power. For God the great Creator & fashioneer of the world, when first he inspired *Adam* by the breath of his mouth into a living and breathing man, he taught him the nature, the proper operations, faculties and vertues of all things contained in the circuit of this Vniuerse. So that if there be any who would ascribe the glory of this invention to man, he is condemned of ingratitude even by the judgment of *Pliny*. But this knowledge was not buried in oblivion with *Adam*: but by the same gift of God was given to those whom he had chosen and ordained for Physicke, to put their helping hands to others that stood in need thereof. Which opinion was not only received in the common manner and by the tacite consent of all Nations, but confirmed by *Moses* in the Scripture. Which thing *Iesus* the sonne of *Sirach* the wisest amongst the Iewes, hath confirmed saying; Honor the Physition with the bonnor due unto him, for the most High hath created him because of necessity: and of the Lord commeth the gift of healing. The Lord hath created Medicines of the Earth and he that is wise will not abhorre them. Give place and bonnor to the Physition, for God hath created him, let him not goe from thee, for thou hast need of him. The *Gracians* who first seeme more fully and with greater fame to have professed the Arte of Physicke, doe in a manner consent with this opinion, in acknowledging *Apollo* to have beene the Inventor thereof, neither did they it without a reasonable cause. For whether by *Apollo* they may understand the Sun who by its gentle and vitall heat doth bring forth, temper and cherish all things; or els some *Heros*, who incited by an excellent and almost divine vnderstanding

*Genes. 1.
Ecclesiast. 38.
1.*

The Preface.

first taught and put in practise the Medicinall vertues of Herbs; in which sense *Ovid* brings him in speaking thus :

*Herbs are of mine invention, and through all
The world, they me the first Phisitian call.*

Plin. l. 7, c. 2.

The originall of Phisicke arising from those beginnings shall always be celebrated, as celestially, and was increased principally after this manner. After *Apollo*, *Æsculapius* his sonne instructed by his father reduced this Arte being as yet rude and vulgar into a little better and more exquisite forme, for which cause he was reputed worthy to be accounted as one of the Gods. At the same time flourished *Chiron* the Centaure who for that he excelled in knowledge of Plants, and taught *Æsculapius*, (as many report) their faculties, is thought by *Pliny* and some others to have bin the inventor of Phisicke. *Æsculapius* had two sons *Podalirius* and *Machaon* who following their fathers steps & professing Phisicke, did principally beautifie and practise that part thereof which is called Chirurgery, and for that cause were accounted the Inventers thereof. After those *Asclepiades* left this Arte much enlarged as hereditary to his posterity : by whose study and diligence, that part of the Arte was invented and annexed, which by a more curious skill searcheth out and cureth those diseases which lye hid within the body. *Hippocrates* the Coan the son of *Heraclidas*, borne of the noble race of *Asclepiades*, Prince of the Phisicians that were before him, perfected Phisicke and reduced it into an Arte and wrote divers bookes thereof in Greeke. *Galen* succeeded him six hundred yeares after, who was a man most famous not only for his knowledge in Phisicke, but also in all other sciences, who faithfully interpreting every thing that was obscure and difficult in the writings of *Hippocrates*, enlarged the science with many volumes. Thus therefore was the beginning, thus the encrease and perfecting the Arte of Phisicke, as much as can be hoped for from mans industry. Although indeed we cannot deny but that Experience hath much profited this Arte, as it hath and doth many other. For as men perceived that some things were profitable, some unprofitable for this or that disease, they set it downe, and so by diligent observation and marking of singularities, they established universall and certaine precepts and so brought it into an Arte. For so we find it recorded in ancient Histories, before the invention of Phisicke, that the *Babylonians* & *Assyrians* had a custome amongst them, to lay their sicke and diseased persons in the porches and entries of their houses, or to carry them into the streets and market places, that such as passed by and saw them, might give them counsell to take those things to cure their diseases, which they had formerly found profitable in themselves or any other in the like affects, neither might any passe by a sicke man in silence. Also *Strabo* writes that it was a custome in *Græce* that those which were sicke should resort to *Æsculapius* his Temple in *Epidaurum*, that there as they slept, by their dreames they might be admonished by the God

what

The Preface.

what meanes they should use to be cured; and when they were freed from their diseales, they writ the manner of their infirmities and the means by which they were cured in tables & fastned them to the pillars of the Temple, not only for the glory of the God, but also for the profit of such, as should afterwards be affected with the like maladies. All which tables (as fame reports) *Hippocrates* transcribed, & so fro those drew the Arte of Phisicke. Beasts also have added much to this Arte. For one man was not only instructed by another, but learned also much from brute beasts, for they by the onely instinct of nature have found out divers herbs, & remedies, by which they freed & preserved themselves from infirmities, which might presently be transferred to mans use. Wherefore considering that such & so many have cōcurred to bring this Arte to perfection, who hereafter dare call in question the excellency therof? cheisly if he respect the subject therof, Mans body, a thing more noble than all other Mundane thing, and for which the rest were created. Which thing moved *Herophilus* in times past to call Phisitions *The hands of the Gods*. For as we by putting forth our hand, do helpe any man out of the water or mud into which he is fallen: even so we doe sustaine those that are throwne downe from the top of health to the gates of death by violence of diseales, with happy medicines, & as it were by some speciall & divine gift deliver them out of the jawes of death. *Homer* the prince of Greek Poets affirms that one Phisition is far more worthy than many other men. All Antiquity gave Phisitions such honor that they worshipped them with great veneration as Gods, or the sons of their Gods. For who is it which is not much delighted with the divine force of healthfull medicines, with which (we see by dayly experience) Phisitiōs, as armed with *Mercuries* rod; do bring back those languishing soules which are even entering the gates of death. Hence it cometh to passe that the divine Poets of ancient times, as *Orpheus*, and *Museus* & *Hesiod*, & the most renowned Philosophers, *Pythagoras*, *Plato*, *Aristotle*, *Theophrastus*, *Chrysippus*, *Cato Censorius*, & *Varro* esteemed nothing more excellent than to excell in the knowledge of Medicines, & to testifie the same by written monuments to Posterity. For what can be more noble or worthy of a generous disposition than to attaine to that by the benefit of Phisicke, that adorned with the ornaments of dignity thou maiest have power over other men, & favoured of Princes, Kings & Emperours, mayest appoint & prescribe to them those things which are profitable to preserve health, & cure their diseases? But if you look for benefit by sciences; then know that the Professors hereof have besides sufficient gain, acquired much honor & many friends. *Hippocrates* comming to *Abdera* to cure *Democritus* of his madnes, not only the men of the City, but also the women, children & people of every age, sexe & ranck went forth to meet him, giving him with a common consent & loud voice the title of a *Tutelary* Deity and father of their Country. But the *Athenians*, for freeing their Country from the plague, with triumphant

phant pompe celebrated playes to his honor, & bountifully let upon his head as if he had beene a king, a Crowne of gold weighing a 1000. peices of their golden coine, & erected his statue, for a perpetuall monument of his piety and Learning. *Erasistratus* the Nephew of *Aristotle* by his daughter, received, freely given him by *Ptolomy* king of Egypt, for the cure of his son, 100. Talents of gold. The Emperour *Augustus* honoured *Antonius Musa* with a golden statue. *Quintus Stertinius* yearly received out of the Emperours Treasury 12000. 500. peices of gold. In the time of our Grandfathers *Petrus Aponensis* called *Conciliator* was so famous through all *Italy* for his knowledge in Phisicke, that he could scarce be intreated to come to any man of fashio that was sick, unles he gave him 50. crownes, for every day he was absent from home: but when he went to cure *Honorius* the Bishop of *Rome*, he received 400. crownes for every day he was absent, Our French Chronicles relate in what credit & estimation *James Cotterius* the Phisition was with *Lewis* the 11. King of *France*; for they report he gave him monethly out of his Treasury 10000. crownes. Phisick in times past hath bin in such esteem with many famous & noble personages, that divers Kings & Princes delighted with the study therof, & desirous to attaine glory & credite therby, called sundry herbs after their own names. For so *Gentian* took its name of *Gentius* king of *Jlyria*; the herb *Lyfimachia* of *Lyfimachus* the king of *Macedon*, the *Mithridaticke* herb or *Scordium*, of *Mithridates* the king of *Fontus* & *Bithinia*; *Achillea* of *Achilles*; *Centorie* of *Chiron* the *Centaure*; *Arthemisia* of *Arthemisia* the Queen of *Caria*. *Attalus* king of *Pergamus*, *Salomon* of *Judea*, *Evax* of *Arabia*, and *Juba* the king of *Mauritania*, were not only inflamed with a desire of the knowledge of plants; but either they have writtē bookes of it, or for the great comodity of posterity, invented by their skil many choise Antidots compounded of divers simples; neither the desire of learning this noble science is yet altogether extinct. As may appear by that *india* plant *Tobaco*, called by some the noble herb, *Catherines* herb & *Medices* herb, but commonly the Queens herb, because *Catherine Medices* the mother of our kings, by her singular study and industry made manifest the excellent vertue it hath in curing malignant ulcers & wounds, which before was unknown to the *French*. For these worthy men understood that their glory, thus fastened & ingrafted into the deepe, & as it were everliving roots of plants, would never decay; but shold be propagated to al posterity in many succeeding ages, growing up with their sprouting & budding shoots, stalks, floures & fruits. Neither did these famous men whil'st they adorned this part of phisick suffer the other, which treats of the dissection of mans body, be buried in oblivion, & without their knowledge; as instructed with the precepts & learning of the wisest men, how artificiall & unimitable by mortall hand this fabrick of our body is: Neither is it probable that *Apis*, *Osiris* and *Ptolomy* kings of Egypt, *Solomon*, *Alexander* the great, *Mithridates*, *Attalus*, seeing they dedicated themselves wholly to the cōtemplation of

nature

The Preface.

natural things, neglected the use of Anatomie, & being men most desirous to know themselves, to have beene ignorant of the structure of there own bodyes being the habitations of their soules immortall & made to the Image of God: seeing they observed with certaine judgment the different lights of the Sun, Moone and stars; and passed over so many lands, so many seas, so many regions so far remote one from another, by waies so terrible by reason of cold, uncouthnes, darknes, by rocks, by fire & sword, with great labour, charge & danger of life, on^{ly} that they might satisfie their minds thirsting after the knowledge of things; and to have left untouched a thing truly noble, admirable, and most worthy of knowledge, easie to be attained by any, and to be acquired without any danger of life, or fortunes.

Seeing there be 3 parts of that Phisicke which at this time we professe, *Chirurgery* which by the use of the hand, *Diet* which with a convenient manner of feeding & ordering the body, & *Pharmacy* that by medicines attempt to expell diseases, & preserve health; The prime Phisitions do not without reason contend which of these may be accounted the cheife. Certainly *Herophilus* had *Pharmacy* in such esteem, that he thought medicines were first mixed & admnistred to the sicke by *Apollo* (whom Antiquity thought a great Deity.) And *Pliny* had so good an opinion of *Diet*, that he exclaimes; The true remedies & Antidotes against diseases are put into the pot & eaten every day by the poore people. Verily al learned men confesse that the manner of curing which is performed by diet, is much more facile & prosperous, than that which is done by medicines; as those things which sought with much labour and cost, are taken with much loathing, and taken are scarce retained, but retained they oft work with much labour & paine: Which things long ago moved *Asclepiades* to exclude the use of medicines, as hurtfull to the stomach. Yet if we will beleewe *Celsus* neither of these parts merit the preheminece, but both of them give place to *Chirurgery*. For seing that fortune is very powerfull in diseases, & the same Meats & Medicines are often good & often vaine, truly it is hard to say, whether the health is recovered by the benefit of *Diet* and *Pharmacy*, or by the strength of the body. Moreover in those cases, in which we most prevaile with medicines, although the profit be more manifest, yet it is evident that health is often sought in vaine even by these things, & often recovered without them. As it may be perceived by some troubled with sore eies, & others with Quartaine feavers, who having bin long troubled by Phisitions are sometimes healed without them. But the effect of *Chirurgery* as it is very necessary, so it is the most evident amongst all the parts of phisicke. For who without *Chirgery* can hope to cure broken, or luxated parts, who wounds & ulcers, who the falling of the Matrix, the stone in the bladder, a member infested with a Gangrene, or Sphacele? Besides, this part also is the most ancient; for *Podalirius* & *Machaon* following their Generall *Agamemnon* to the Trojane wars, yeilded no small

Phisicke is divided into 3 parts.

The Preface.

The excellency of
Chirurgery.

small comfort to their fellow Soldiers. Whom notwithstanding *Homer* affirms not to have given any helpe in the pestilence, nor in divers other diseases, but onely were accustomed to heale wounds by instruments and medicines. And if the difficulty of learning it argue the excellency of the Arte, who can doubt but Chirurgery must be the most excellent, seeing that none ought to be accounted a Chirurgeon or which can performe his duty, without the knowledge of Diet & Pharmacy? But both the other can performe their parts without Chirurgery. As we may beleieve *Galen*. But if we consider the matter more neerly according to truth; we shall understand those three parts have a certaine common bond, and are very neere of kinred, so that the one implores the ayde of the other; neither can the Physition doe any thing praiseworthy without the conspiracy and joynt consent of these three; therefore in ancient times there was but one performer and user of all the three parts. But the multitude of men dayly encreasing, and on the contrary mans life decreasing, so that it did not seeme able to suffice for to learne and exercise all the three, the workmen devided themselves. Wherefore that which happens to any man either by lot, or counsell, that let him follow, maintaine and onely use, as mindful how short his life is, and how long the Arte.

number of the Bookes, least any
should thinke some wanting, fin-
ding but 26. in the Latine, and
29. in the French.

AN INTRODVCTION OR COMPENDIOVS VVay to Chyrurgerie.

CHAP. I.

What Chyrurgerie is.

CHYRVRGERIE is an Art, which teacheth the way by reason, how by the operation of the hand we may cure prevent and mitigate diseases, which accidentally happen unto us. Others have thought good to describe it otherwise, as that; it is that part of Physicke which undertaketh the cure of diseases by the sole industry of the hand; as by cutting, burning, sawing off, uniting fractures, restoring dislocations, and performing other workes, of which we shall hereafter treat. Chyrurgery also is thus defined by the Author of the medi-

The definition of Chyrurgerie.

cinall Definitions; The quicke motion of an intrepide hand joyned with experience: or an artificiall action by the hands used in Physicke, for some convenient intent. Yet none must thinke to attaine to any great perfection in this Art, without the helpe of the other two parts of Physicke; I say of Diet and Pharmacie, and the divers application of proper medicines, respecting the condition of the causes, diseases, symptomes, and the like circumstances, which comprehended under the names of things naturall, not naturall, and besides nature (as they commonly call them) wee intend to describe in their proper place. But if any reply, that there be many which doe the workes of Chirurgery, without any knowledge of such like things, who notwithstanding have cured desperate diseases with happy successe; let them take this for an answer, that such things happen rather by chance, than by the industry of the Art, and that they are not provident that commit themselves to such. Because that for some one happy chance, a thousand dangerous errors happen afterwards, as *Galen* (in divers places of his Method) speaks against the Emperickes. Wherefore seeing wee have set downe Chirurgery to be a diligent operation of the hands, strengthened by the assistance of Diet and Pharmacie, wee will now shew, what, and of what nature the operations it are.

What necessary for a Chirurgeon.

CHAP. II.

Of Chirurgicall operations.

The nature of
a Chirurgion.

Experience
more necessa-
ry for a Chi-
rurgion, than
Art.

Examples of

cles of the
eyes.

Examples of
replacing.

Example of
separating
things joyned
together.

Examples of
uniting things
disjoyned.

Examples of
supplying de-
fects.

Five things are proper to the dutie of a Chirurgian; To take away that which is superfluous; to restore to their places, such things as are displaced; to separate those things which are joyned together; to joyne those which are separated; and to supply the defects of nature. Thou shalt fare more easily and happily attaine to the knowledge of these things by long use and much exercise, than by much reading of Bookes, or daily hearing of Teachers. For speech how perspicuous and elegant soever it be, cannot so vividly expresse any thing, as that which is subjected to the faithfull eyes and hands.

We have examples of taking away that which abounds, in the amputation, or cutting off a finger, if any have sixe on one hand, or any other monstrous member that may grow out: in the lopping off a putrified part inwardly corrupted; in the extraction of a dead child, the secundine, mole or such like bodies out of a womans wombe; in taking downe of all Tumors, as Wens, Warts, Polypus, Cancers, and fleshy excrescences of the like nature; in the pulling forth of bullets, of peeces of maile, of darts, arrowes, shells, splinters, and of all kind of weapons in what part of the body soever they be. And hee taketh away that which redounds, which plucks away the haire of the eye-lids which trouble the eye by their turning in towards it: who cuts away the web, possessing all the * *Adnata*, and part of the * *Cornea*: who letteth forth suppurated matter; who taketh out stones in what part soever of the body they grow; who puls out a rotten or otherwise hurtfull tooth, or cuts a naile that runs into the flesh; who cuts away part of the *uvula*, or haire that grow on the eye-lids; who taketh off a Cataract; who cuts the navill or fore-skinne of a child newly borne, or the skinnie caruncles of womens privities.

Examples of placing those things which are out of their naturall site, are manifest in restoring dislocated bones; in replacing of the guts and kall fallen into the cecds, or out of the navill or belly by a wound, or of the falling downe of the wombe, fundament, or great gut, or the eye hanging out of its circle, or proper place.

But wee may take examples of disjoyning those things which are continued from the fingers growing together, either by some chance, as burning, or by the imbecillitie of the forming facultie: by the disjunction of the membrane called *Hymen*, or any other troubling the necke of the wombe, by the dissection of the ligament of the tongue, which hinders children from sucking and speaking, and of that which hinders the *Glans* from being uncovered of the foreskinne; by the devision of a varicous veine, or of a halfe cut nerve or tendon, causing convulsion: by the division of the membrane stopping the auditory passage, the nose, mouth, or fundament, or the stubborne sticking together of the haire of the eye-lids. Referre to this place all the workes done by Causticks, the Saw, Trepan, Lancet, Cuppinglasses, Incision Knife, Leaches, either for evacuation, derivation or revulsion sake.

The Chirurgion drawes together things separated, which healeth wounds by stitching them, by bolstering, binding, giving rest to, and fit placing the part: which repaires fractures; restores luxated parts; who by binding the vessell, staie the violent effusion of blood: who cicatrifeth cloven lips, commonly called hare-lips; who reduces to equalitie the cavities of Vicers, and Fistula's.

But hee repaires those things which are defective, either from the infancy, or afterwards by accident, as much as Art and Nature will suffer, who sets on an eare, an eye, a nose, one or more teeth; who fills the hollownesse of the palat eaten by the Poxe, with a thinne plate of gold or silver, or such like; who supplies the defect of the tongue in part cut off, by some new addition; who fastens to a hand, an arme or legge with fit ligaments workemanlike; who fits a doubler bumbasted, or made with iron plates to make the body straight; who fills a shoe too big with corke, or fastens a stocking or socke to a lame mans girdle to helpe his gate. We will treate more fully of all these in our following Worke. But in performing those things with the hands,

we cannot but cause paine : (for who can without paine cut off an arme, or legge, de-
vide and teare asunder the necke of the bladder, restore bones put out of their places,
open ulcers, bind up wounds, and apply cauteries, and doe such like?) notwithstanding
the matter often comes to that passe, that unlesse wee use a judicious hand, wee
must either die, or leade the remnant of our lives in perpetuall misery. Who
therefore can iustly abhorre a Chirurgion for this, or accuse him of crueltie? or de-
sire they may be served, as in ancient times the Romanes served *Archagatus*, who at the
first made him free of the Citty, but presently after, because he did somewhat too cru-
elly burne, cut and performe the other workes of a good Chirurgion, they drew him
from his house into the Campus Martius and there stoned him to death, as wee have
read it recorded by *Sextus Cheronius Plutarcho* : Necce by his daughter. Truly it was
an inhumane kind of ingratitude, so cruelly to murder a man intent to the workes of
so necessary an Art. But the Senate could not approve the act, wherefore to expiate
the crime as well as then they could, they made his Statue in gold, placed it in *Athen-*
lapius his Temple and dedicated it to his perpetuall memorie. For my part I very well
like that saying of *Celsus* ; A Chirurgeon must have a strong, stable, and intrepide
hand, and a minde resolute and mercilesse, so that to heale him he taketh in hand, he
be not moved to make more haste than the thing requires ; or to cut lesse than is need-
full ; but which doth all things as if he were nothing affected with their cries ; not gi-
ving heed to the judgement of the vaine common people, who speake ill of Chirurgi-
ons because of their ignorance.

ties of a good
Chirurgeon.

CHAP. III.

Of things Naturall.

What the Chirurgion may rightly and according to Art, performe the fore-
said workes, he must set before his eyes certaine Indications of working: O-
therwise he is like to become an Empericke, whom no Art, no certaine rea-
son, but onely a blind temerity of fortune moves to boldnesse and action. These In-
dications of actions are drawne from things (as they call them) naturall, not naturall,
and besides nature, and their adjuncts, as it is singularly delivered of the Ancients, be-
ing men of an excellent understanding. Wherefore we will prosecute according to
that order, all the speculation of this Art of ours. First therefore things naturall are so
termed, because they constitute and containe the nature of mans body, which wholly
depends of the mixture and temperament of the 4. first bodies, as it is shewed by *Hip-
pocrates* in his Booke *de Natura humana* : wherefore the consideration thereof belongs
to that part of Physicke which is named *Physiologia* ; as the examination of things not
naturall to *Diatetice*, or Diet, because by the use of such things it endeavours to retaine
and keepe health : but *Therapeutice* or the part which cures the diseases, and all the
affects besides nature, challenges the contemplation of those things which are not a-
greeable to nature. But the things which are called naturall may be reduced to seven
heads : besides which there comes into their fellowship, those which wee terme
annexed.

From whence
we must draw
indications.

What things
are called na-
turall.

To what part
of Physicke
things not na-
tural pertaine.
To what
things besides
nature.

| | Actions. | | Region. |
| | Spirits. | | Vocation of life. |

CHAP. IIII.

Of Elements.

What an Element is.

Elements are understood by reason, not by sense.

Why he expressed the Elements by these names or qualities.

Two principal qualities are in each Element.

Why the Aire heats not so vehemently, as the Fire.

AN Element (by the definition which is commonly received amongst Physicians) is the least and most simple portion of that thing which it composeth: or that my speech may be the more plaine: the foure first and simple bodies are called Elements; Fire, Aire, Water, and Earth; which accommodate and subject themselves as matter to the promiscuous generation of all things which the Heavens engirt, whether you understand things perfectly, or unperfectly mixed. Such Elements are onely to be conceived in your minde, being it is not granted to any external sense to handle them in their pure and absolute nature. Which was the cause that Hippocrates expressed them not by the names of substances, but of proper qualities; saying, Hot, Cold, Moist, Drie; because some one of these qualities is inherent in every Element, as his proper and essentiall forme, not onely according to the excesse of latitude, but also of the active facultie; to which is adjoynd another simple qualitie, and by that reason principall, but which notwithstanding attaines not to the highest degree of his kinde, as you may understand by Galen in his first Booke of Elements. So, for example sake, in the Aire wee observe two qualities, Heat, and Moisture, both principall, and not remitted by the commixture of any contrary quality, for otherwise they were not simple. Therefore thou maist say, what hinders that the principall effects of heat shew not themselves as well in the Aire, as in the Fire? because as we said before, although the Aire have as great a heat according to his nature, extent and degree, no otherwise than Fire hath, yet it is not so great in its active qualitie. The reason is, because that the calfa&orie force in the Aire is hindered, and dulled by societie of his companion and adjoynd qualitie, that is, Humidity which abateth the force of heat, as on the contrary, drinesse quickneth it. The Elements therefore are endewed with these qualities.

| | | | | | | | | |
|-----------------------------|---|-------|---|----|---|-----------------|---|----------------------------|
| Names of the substances; | { | Fire | } | is | { | Hot and drie. | } | Names of the qualities. |
| | | Aire | | | | Moist and hot. | | |
| | | Water | | | | Cold and moist. | | |
| | | Earth | | | | Cold and drie. | | |

How the Elements may be understood to be mixed in compound bodies.

Why of the first qualities, two are accounted active, and two passive.

These foure Elements in the composition of naturall bodies, retain the qualities they formerly had, but that by their mixture and meeting together of contraries, they are somewhat tempered and abated. But the Elements are so mutually mixed one with another, and all with all, that no simple part may be found; no more than in a masse of the Emplaister *Diacalcitheos* you can shew any *Axungia*, oyle, or licharge by it selfe; all things are so confused and united by the power of heate, mixing the smallest particulars with the smallest, and the whole with the whole, in all parts. You may know and perceive this concretion of the foure Elementary substances in one compound body, by the power of mixture, in their dissolution by burning a pile or heape of greene wood. For the flame expresses the Fire, the smoke the Aire, the moisture that sweats out at the ends, the Water, and the ashes, the Earth: You may easily perceive by this example so familiar and obvious to the senses what dissolution is, which is succeeded by the decay of the compound body; on the contrary, you may know that the coagmentation, or uniting and ioyning into one of the first mixed bodies is such, that there is no part sincere, or without mixture. For if the heat which is predominant in the fire, should remaine in the mixture in its perfect vigor, it would consume the rest by its pernicious neighbourhood; the like may be said of Coldnesse, Moisture, and Drinesse; although of these qualities, two have the title of Active, that is, Heat, and Coldnesse, because they are the more powerfull; the other two Passive, because they may seeme more dull and slow, being compared to the former. The temperaments of all sublunarie bodies arise from the commixture of these substances & elementary qualities, which hath bin the principall cause that moved me to treat of the Elements. But I leave the force and effects of the Elementary qualities

qualities to some higher contemplation, content to have noted this, that of these first qualities, (so called, because they are primarily and naturally in the four first bodies) others arise and proceed, which are therefore called the second qualities: as of many these, Heaviness, Lightness, variously distributed by the four Elements, as the Heat, or Coldness, Moistness or Drienesse, have more power over them. For of the Elements, two are called light, because they naturally affect to move upwards: the other two heavy, by reason they are carried downward by their own weight. So we thinke the fire the lightest, because it holds the highest place of this lower world; the Aire which is next to it in site, wee account light; for the water which lies next to the Aire, we judge heavy; and the earth the center of the rest we judge to be the heaviest of them all. Hereupon it is, that light bodies, and the light parts in bodies, have most of the lighter Elements; as on the contrary heavy bodies have more of the heavier. This is a briefe description of the Elements of this fraile world, which are onely to be discerned by the understanding, to which I thinke good to adjoyne another description of other Elements, as it were arising or flowing from the commixture of the first; for besides these, there are said to be Elements of generation and Elements of mans body. Which as they are more corporall, so also are they more manifest to the sense. By which reason *Hippocrates* being moved, in his Booke *de Natura humana*, after he had described the nature of Hot, Cold, Moist and Drie, he comes to take notice of these by the order of composition. Wherefore the Elements of our generation, as also of all creatures which have blood, are seed and mensstruous blood. But the Elements of our bodies are the solid and similar parts arising from those Elements of generation. Of this kind are bones, membranes, ligaments, veines, arteries, and many others manifest to the eyes, which wee will describe at large in our Treatise of Anatomie.

Why the first qualities are so called.
What the second qualities are.
What Elements are light, what heavy.

What the Elements of generation are.

What the Elements of mixt bodies.

CHAP. V.

Of Temperaments.

Temperament is defined a proportionable mixture of hot, cold, moist and drie; or, it is a concord of the first disagreeing faculties. That harmony springs from the mixture of the four first bodies of the world. This whether Temperament or concord is given to Plants and brute beasts for the beginning of their life, and so consequently for their * life and forme. But as Plants are inferior in order and dignitie to beasts, so their * life is more base and infirme, for they have onely a growing facultie by which they may draw an Alimentarie joyce from the Earth, as from their mothers breasts, to preserve them and their life, by which they may grow to a certaine bignesse; and lastly, by which they may bring forth their like for the perpetuall continuance of their kind. But the * life of beasts have to the three former the gift of sense annexed; by benefit whereof, as by a certaine inward knowledge, they shun those things that are hurtfull, and follow those which profit them, and by the power of their will, they move themselves whither they please. But the soule of man farre more perfect and noble than the rest, ariseth not from that earthly mixture and temper of the Elements, but acknowledgeth and hath a farre more divine offspring, as we shall teach hereafter.

What a Temperament is.

* *Anima*.
What the life performs in Plants.

* *Anima*.
What in beasts.

Mans soule comes from above.

The manifold division of a Temperament.

They divide a Temperament at the first division into two kinds; as one a temperate, another an untemperate. The untemperate is of two sorts; the one wholly vicious, which hath altogether exceeded the bounds of mediocritie: the other which hath somewhat strayed from the mediocritie of temper, but notwithstanding is yet contained within the limits of health: as that which brings no such evident harme to the actions, but that it somewhat hinders them, so that they cannot so well and perfectly performe their duties. But the vicious Temperament doth three manner of wayes corrupt the functions, either by weakning, depraving or abolishing them. For so stupor, or astonishment, diminisheth and sloweth the quicknesse of motion; convulsion depraves it; the Palsie abolisheth it, and taketh it away. The temperate Temperament

A Temperament, and Power.

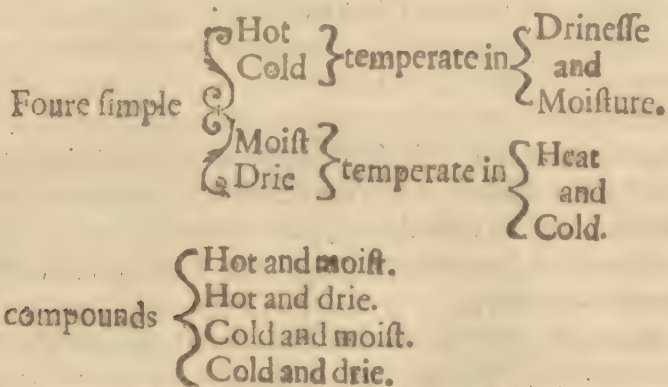

* *Ad pondus,
vel ad iustitiam.*

A tempera-
ment *ad iustitiam*.

The tempera-
ment of a
bone.

perament is also divided into two kinds; which is either to equality of weight, or Iustice. It is called a temperature to weight which ariseth from the equall force of exactly concurring qualities, and as placed in a perfect ballance, drawes downe neither to this nor that part. They thinke the example of this Temperament to appeare in the inner skinne of the fingers ends of a man tempered to Iustice. For seeing the most exquisite touch resides there, they ought to be farre from all excesse of contrariety; for otherwise being corrupted by too much heat or cold, moisure, or drinesse, they could give no certaine judgement of the tangible qualities. For which thing nature hath excellently provided in the fabricke and coagmentation of the parts of which the skinne consists. For it is composed of hot and moist flesh, and therefore soft, and of a tendon and nerve cold and drie, and therefore hard, which are not onely equally fitted and conjoynd, but wholly confused and mixed together, by which it comes that removed from all extremes of opposition, it is placed in the midst, as a rule to judge of all the excessees that happen to the touch. So it was fit the eye, which was to be the instrument of sight, should be tinctured with no certaine colour, that it might be the lesse deceived in the judgement of colours. So it was convenient the hearing should not be troubled with any distinct sound, whereby it might more certainly judge of equall and unequall sounds, not distinguished by a ratable proportion; neither was it fit the tongue should have any certaine taste, lest the access of that taste should deceive it in knowing and judging of so many different tastes. The Temperature tempered to iustice is that, which although it is a little absent from the exact and severe parity of mixed qualities, yet hath that equalitie which doth fully and abundantly suffice for to performe all the functions fitly and perfectly which nature doth require, wherefore we can judge no otherwise of it than by the integritie of the Actions. For hence it tooke its name, for as distributive Iustice equally gives to every one rewards, or punishment according to their deserts; so nature having regard to all the parts of the bodie, gives them all that temper which may suffice to performe those duties, for which they are ordained. Let us for an example consider a Bone; no man doubts but that, like as the other similar parts of the body proceeds from the mixture of the foure Elements: but neverthelesse nature waighing the use of it, and ordaining it to support the rest of the body, would have more of the terrene and drie Element infused into it, that it might be the stronger and firmer to sustaine weight. But a Ligament, seeing it was made for other uses, hath lesse of that earthly drienesse than the bone, but more than the flesh, altogether fitted to its nature. So it hath seemed good to nature to endue all the parts of the body, not onely with an equall portion, but also proportion of Elements and qualities; wee call that a temperament to Iustice: and wee say that it is in Plants, Brute beasts, and all naturall bodies, which enjoy that temper and mediocritie, which may be agreeable to their nature. Hereupon by comparison arise eight kindes of intemperate tempers, as

The kindes of
intemperate
tempers.

But these temperaments are either of the whole body, or of some part thereof

and that either { principall, as { the Braine.
the Heart.
the Liver.
the Stones.
or { of the rest of the parts composed of other which have no principality in the body.

Again, such temperaments are either healthfull, which suffice perfectly to performe their actions; or unhealthfull, which manifestly hurt them, the signes whereof may be read described by *Galen*. And you must observe that when we say the body, or any part of it is hot, wee understand more hot than is fit for one of that kinde which is tempered to justice; as when we say a man hath a hot liver, wee meane his liver is hotter, than a man justly tempered should have; for all other tempers, whether of the whole body, or any of the parts thereof, are to be referred to this; and in the cure of diseases we must looke upon it, as the marke, and labour to preserve it by the use of convenient things, as much as lies in our power. Wherefore because it is very necessary to know the distinction of temperaments, I have thought good in this place, briefly to handle the temperaments of the parts of the body, ages, seasons of the yeare, humors, and medicines. Therefore the temperaments of the parts of our body are of this nature, not onely by the judgement of the touch of a mans hand which is justly tempered / who is often deceived by flowing heate, which spread from the heart into all the body, imparts a certaine kinde of heate to all the parts, / but also by the rule of their reason, composition and substance, as

Lib. 2. de Temper. & in Ar. se m. 68.

What the temperaments of mans body are.

A Bone is the most drie and cold.

A Gristle lesse than it.

A Ligament lesse than a Gristle.

A Tendon is so much drier and colder than the membrane, by how much it in the same temper exceeds a Veine and Arterie. Then follow the harder veines, for the softer are in a middle temper of driness and moisture, like as the skinne; although all both soft and hard, are of a cold temper. Wherefore all these parts of their owne nature are cold and without bloud: although the veines and arteries waxe hot, by reason of the heate of the bloud they containe, which notwithstanding also borroweth that heat from the heart, as a part most hot, and softer than the skinne; the liver next followeth the heart, in the order of the hotter parts, which is far softer than the skinne it selfe: for if, according to *Galen's* opinion, the heart is somewhat lesse hard than the skinne, and that is farre harder than the liver, as appeares by touching them, it must necessarily follow that the liver much exceeds the skinne in softnesse; I understand the skinne simple, and separated from the flesh lying under it, to which it firmly cleaves. The flesh is more moist and hot than the skinne, by reason of the bloud dispersed in it. The spiall marrow is colder and moister than the skinne; but the braine so much exceeds it in moisture, as it is exceeded by the fat. The lungs are not so moist as the fat, and the spleene, and kidnies, are of the like nature, and nevertheless they are all moister than the skinne.

Ad finem lib. de temper.

According to the diversities of ages, the temperaments both of the whole body, and all its parts, undergoe great mutations; for the bones are farre harder in old men than in children, because our life is, as it were a certaine progresse to driness, which when it comes to the height consequently causeth death. Wherefore in this place we must speake of the Temperaments of ages, when first we shall have defined what an age is. Therefore an age is defined, a space of life in which the constitution of the bodie of its selfe and owne accord, undergoeth manifest changes; the whole course of life hath foure such ages. The first is childhood, which extends from the birth to the eighteenth yeare of age, and hath a hot and moist temper, because it is next to the hot and moist beginnings of life, seed and bloud: Youth followeth this which is prolonged from the eighteenth, to the twentie fift yeare, and is temperate, and in the midst of all excesses; Mans estate succeedeth youth, which they deny to extend beyond the thirtie fift yeare of age, in its proper temper it is hot and drie: whereby it commeth to passe that then the heate is felt more acride and biting, which in childhood seemed milde; because the progresse of the life to driness hath much waisted the native humiditie.

The temperaments of ages.

What an age is.

Then succedes old age ever devided into two parts; the first whereof extends from the thirtie fift, to the fortie ninth yeare; those of this age are called old men (* but we commonly call them middle aged men.) The latter is as it were devided by *Galen* into three degrees; the first whereof are those, who having their strength sound and firme undergoe civill affaires and busineses: which things those which are in the second de-

Old age devided into two parts. * Three degrees of the second part of old age.

gree

Old men have
their solid
parts drie.

gree of old age cannot doe, because of the debilitie of their now decaying strength: but those which are in the last degree are afflicted with most extreme weaknesse and miserie, and are as much deprived of their senses and understanding, as of the strength of their bodies; whereof arose this Proverbe, *Old men twice children*. Those old men of the first ranke are pleasant, and courteous, and those we say are beginning to grow old, or in their greene old-age; those of the second sort delight in nothing but the beord and bed; but old decrepit men of the last order, thinke of nothing else, than their graves and monuments. Their firme and solid parts are of a cold and drie temperature, by reason of the decay of the radicall moisture, which the inbred heate causeth in the continuance of so many years. Which thing may happen in a short space, by the vehement flame of the same natural heate, turned by feavours into a fiery heate. But if any to prove old men moist, will object, that they cough up, and spit much, I will answer him, as an old Doctor once said; That a pitcher filled with water may powre forth much moisture; yet no man will deny but that such a vessell of its owne terrene nature and matter is most drie; so old men may plainly be affirmed to be moist, by reason of their defect of heate, and abundance of excrements. But this description of ages, is not to be taken so strictly, as alwayes to be measured by the spaces and distances of yeares, for there are many which by their owne mildemour, seeme elder at fortie, than others doe at fiftie.

A comparison
of the foure
ages to the
foure seasons
of the yeare.

Lastly, the famous Philosopher *Pythagoras*, devided mans life into foure ages, and by a certaine proportion compared the whole course thereof to the foure seasons of the yeare; as childhood to the Spring, in which all things grow and sprout out, by reason of plenty and abundance of moisture. And youth to the Summer, because of the vigour and strength which men enjoy at that age. And mans estate, or constant age to Autumne, for that then after all the dangers of the forepassed life, the gifts of discretion and wit acquire a seasonableness, or ripeness, like as the fruits of the earth enjoy at that season. And lastly, he compares old age to the sterile and fruitlesse Winter, which can ease and console its tediousnesse by no other meanes, than the use of fruits gathered and stored up before, which then are of a cold and troublesome condition. But for extreme old age, which extends to eightie, or a hundred yeares, it is so cold and drie, that those which arrive at that decrepit age are troublesome, harsh, touchy, froward, crabby, and often complaining, untill at the length deprived of all their senses, tongue, feet, and understanding, they doting, returne againe to childishnesse, as from the stasse to the start. And thus much of the Temperaments of ages.

The temper
of the seasons
of the yeare.

But now in like manner we will explaine the temperatures of the seasons of the yeare, which are foure, the Spring, Summer, Autumne, Winter. The Spring continues almost from the twelfth or thirteenth day of March, to the midst of May, *Hippocrates* seemeth to make it hot and moist; which opinion seemeth not to have sprung from the thing it selfe, but from an inveterate error of the ancient Philosophers, who would fit the temperaments of the foure seasons of the yeare, as answering in proportion to the temperatures of the foure ages.

Now the
Spring is tem-
perate.

Apher. 9. sect. 3

Apher. 20. sect. 3

Autumne
quali.

For if the matter come to a just triall, all men will say the Spring is temperate, as that which is in the midst of the excesse of heate, cold, moisture and drincle; not onely by comparison because it is hotter than Summer, and colder than Winter; but because it hath that qualirie of its owne proper nature. Wherefore it is said of *Hippocrates*: The Spring is most holesome and least deadly; if so be that it keepe its native temper, from which if it decline, or succeed a former untemperate season, as Autumne, or Winter, it will give occasion to many diseases described by *Hippocrates*; not that it breeds them, but because it brings them to light, which before lay hid in the body. Summer is comprehended in the space of almost foure moneths; it is of a hot and drie temper, a breeder of such diseases as proceed from choler, because that humor at this time is heaped up in many bodies by adustion of bloud bred in the Spring; but all such diseases doe speedily runne their course. The beginning of Autumne, is from the time the Sunne enters into Libra, and endures the like space of time as the Spring. But when it is dry, it hath great inequality of heate and cold; for the mornings and evening being very cold, the noondayes on the contrary are exceeding

ding hot. Wherefore many diseases are in Autumn, and then long and deadly especially if they incline to wards winter: because all dayly and sodaine changes to heat and cold are dangerous. The winter possesse the remnant of the yeare, and is cold and moist, it encreases naturall heat, stirs up the appetite, and augments Phlegme. It encreases heat by *Antiperistasis*, or contrariety of the encompassing aire, which being then cold prohibits the breathing out of heate: whereby it happens that the heat being driven in and hindered from dissipation, is strengthened by counting its forces. But it augments Phlegme, for that men are more greedy, the Appetite being encreased by the strengthened heat: from whence proceeds much crudity and a large store of diseases, especially Chronicke or Long which spread and encrease rather in this winter season than in any other part of the yeare. To this discourse of the temper, of the seasons of the yeares, is to be revoked the variety of tempers which happens every day, which certainly is not to be neglected, that there may be place of election, especially if nothing urge. For hitherto belongs that saying of *Hippocrates*; When in the same day it is one while hot, another cold, Autumnall diseases are to be expected. Therefore an Indication taken from hence is of great consequence to the judgement of diseases; for if it agree with the disease, the disease is made more contumacious, and difficult to cure. Whereupon the Patient and Physicion will have much trouble; but if on the contrary it reclame and dissent, the health of the Patient is sooner to be expected. Neither is it a thing of lesse consequence to know the customes and habits of the places and Countries in which we live, as also the inclination of the Heavens and temperature of the Aire; but let vs leave these things to be considered by Naturall Philosophers, that we may deliver our judgement of the temperaments of *Humors*. blood, as that which answers to the Aire in proportion, is of a hot and moist nature, or rather temperate, as *Galen* testifies; for, saith he, it is certaine and sure that ~~the~~ The blood is neither hot, nor moist, but temperate as in its first composition none of the 4 first qualities exceeds other by any manifest excessse, as he repeats it upon the 39. sentence. Phlegme, as that which is of a waterish nature, is cold and moist; no other-wise than Choler being of a fiery temper, is hot and dry. But Melancholy assimilated to Earth, is cold and dry. This which we have spoke in generall of Phlegme and Melancholy, is not alwayes true in every kind of the said humors. For salte Phlegme is of a hot and dry temperature, as also all kinds of Melancholy which have arose, or sprung by adustion from the native and Alimentary, as we will teach in the following Chapter. Now the Temperaments of Medicines have not the same forme of judgement, as those things which we have before spoken of; as, not from the Elementary quality which conquering in the contention and mixture, obtains the dominion; but plainly from the effects which taken or applyed they imprint in a temperate body. For so we pronounce those things hot, cold, moist, or dry, which produce the effects of Heate, Coldnes, Moisture or Drynes. But we will defer the larger explication of these things to that place, where we have peculiarly appointed to treat of Medicines; where we will not simply enquire whether they be hot or cold, but what degree of heate and cold, or the like other quality: in which same place we will touch the temperature and all the Nature of tastes, because the certainest judgement of medicines is drawne from their tastes. Hitherto of Temperaments, now we must speake of Humors whose use in Physicall speculation is no lesse than that of Temperaments.

CHAP. VI.

Of Humors.

TO know the nature of *Humors* is a thing notonely necessary for Physicions, but also for Chirurgeons, because there is no disease with matter which arises from some one, or the mixture of more *Humors*. Which thing *Hippocrates* understanding, writ, every Creature to be either sicke or well according to the Con-

Hum.

ditation of the *Humors* in the body. And certainly all putride feavers proceed from the putrifaction of *Humors*. Neither doe any acknowledge any other originall or distinction of the differences of Abscesses or Tumors: neither do ulcerated, broke or otherwise wounded members hope for the restoration of continuity, from other than from the sweet falling downe of humors to the wounded part. Which is the cause that often in the cure of these effects, the Physicians are necessarily busied in tempering the Blood, that is, bringing to a mediocrity the 4 humors composing the masse of blood, if they at any time offend in quantity, or quality. For whether if any thing abound, or digresse from the wonted temper in any excessse of heat, cold, viscosity, grossenes, thionnes, or any such like quality, none of the accustomed functions will be well performed. For which cause those cheife helpes to preserve and restore health have beene divinely invented; *Phlebotomy*, or bloodletting which amends the quantity of too much blood; and purging which corrects and drawes away the vicious quality. But now let us begin to speak of the *Humors*, taking our beginning from the definition.

The helpes of
Health.

What an
humor is.

of Choler and
Melancholy.

Four unlike
Humors in the
Bloody.

A comparison
of blood and
new wine.

An Humor (is called by Physicians) what thing so ever is Liquide and flowing in the body of living Creatures endued with Blood, & that is either natural, or against nature. The naturall is so called because it is fit to defend, preserve and sustaine the life of a Creature. Quite different is the nature & reason of that which is against nature. Again the former is either Alimentary, or Excrementitious; The Alimentary which is fit to nourish the body, is that Humor which is contained in the veines and arteries of a man which is temperate & perfectly vel; & which is understood by the general name of blood which is let out at the opening of a veine. For blood otherwise taken is an Humor of a certaine kind, distinguished by heate and warmnesse from the other Humors comprehended together with it, in the whole masse of the blood. Which thing that it may the better be understood, I have thought good in this place to declare the generation of Blood by the efficient and materiall causes. All things which we eate or drink are the materialls of blood, which things drawne into the bottome of the ventricle by its attractive force, and there detained, are turned by the force of concoction implanted in it, into a substance like to Almond Butter. Which thing although it appeare one and like it selfe, yet it consists of parts of a different nature, which not only the variety of meats, but one & the same meate yeelds of it self. We terme this *Chylus* (when it is perfectly concocted in the stomacke). But the * Gate-veine receives it driven from thence into the small guts, and sucked in by the Meseraicke veins, and now having gotten a litle rudiment of Change in the way, carries it to the Liver, where by the blood making faculty which is proper and naturall to this part, it acquires the absolute and perfect forme of blood. But with that blood at one and the same time and action all the humors are made whether Alimentary or excrementitious. Therefore the blood that it may performe its office, that is, the faculty of nutrition, must necessarily be purged and clesed from the two excrementitious humors. Of which the bladder of Gall drawes one which we call Yellow Choler, and the Spleen the other which we terme Melancholy. These two humors are naturall, but not Alimentary, or nourishing, but of another use in the body, as afterwards we will shew more at large. The blood freed from these 2 kinds of excrements is sent by the veines and Arteries into all parts of the body for their nourishment. Which although then it seeme to be of one simple nature, yet notwithstanding it is truly such, that foure different and unlike substances may be observed in it, as blood properly so named, Phlegme Choler and Melancholy, not only distinct in colour, but also in taste effects and qualities. For as *Galen* notes in his booke *De Natura humana*, Melancholy is acide or soure, choler bitter, Blood sweet, Phlegme unsavory. But you may know the variety of their effects, both by the different temper of the nourished parts, as also by the various condition of the diseases springing from thence. For therefore such substances ought to be tempered and mixed amongst themselves in a certaine proportion, which remaining health remaines, but violated, diseases follow. For all acknowledge that an *Oedema* is caused by Phlegmatick, a *Scirrhus* by Melancholike, an *Erysipelas* by Cholericke, and a *Phlegmone* by pure and laudable blood. *Galen* reaches by a familiar example of new wine presently taken from the presse, that these 4 substances are contained in that one Masse, and mixture of the blood. In which every one observes

observes 4. distinct Essences ; for the flower of the wine working up swims at the top, the dregs fall downe to the bottome, but the crude and watery moisture mixed together with the sweet and vinous liquor, is every where diffused through the body of the wine, the flower of the wine represents Choler, which bubling up on the superficies of blood, as it concretes and growes cold, shineth with a golden colour; the dregs Melancholy, which by reason of its heaviness ever sinketh downward, as it were the Mudd of the blood; the crude and watery portion Phlegme: for as that crude humor, except it be rebellious in quantity, or stubborn by its quality, there is hope it may be changed into wine, by the naturall heate of the wine; so Phlegme which is blood halfe concocted, may by the force of native heat be changed into good and laudable blood. Which is the cause that nature decreed, or ordained no peculiar place, as to the other 2. humours, whereby it might be severed from the blood; But the true and perfect liquor of the wine represents the pure blood, which is the more laudable and perfect portion of both the humors of the confused Masse. It may easily appeare by the following scheme, of what kind they all are, and also what the distinction of these foure humors may be.

Phlegme is
blood halfe
concocted.
Why it hath
no proper re-
ceptacle.

| | NATURE | CONSISTANCE | COLOUR | TASTE | USE. |
|---------------------|---|--|--|---|---|
| Blood is | Of Nature sery, hot and moyst, or ra- ther tempe- rate, | Of indifferent con- sistence, neither too thicke nor too thin, | Of Colour red rosy or Crim- son, | Of Taste sweete, | Of such use, that it cheerly serves for the nourishment of the fleshy parts, and caried by the vessels im- parts heate to the whole body. |
| Phlegme is | Of Nature watery, cold and moist, | Of Consistence liquid, | Of Colour white | Of Taste sweet, or rather un- savory, for we com- mend that water which is unsavory | Fit to nourish the braine and all the other cold and moist parts, to temper the heate of the blood, and by its slipperines to helpe the moti- on of the joynts. |
| Choler is | Of Nature fiery, hot and drie, | Of Consistence Thin, | Of Colour yellow, or pale, | Of Taste bitter, | It provoketh the expulsive faculty of the guts, attenuates the Phlegme clea- ving to them, but the Alimentary is fit to nourish the parts of like tem- per with it. |
| Melan- choly is. | Of Nature earthly, cold and dry. | Of Consistence grosse and muddy, | Of Colour blackish | Of taste acide, sour or biting. | Stirs up the Ap- petite, nourishes the spleene and all the parts of like temper to it, as the Bones. |

Bloud hath its neereſt matter from the better portion of the *Chylus*: and being begunne to be laboured in the veines, at length gets forme and perfection in the liver; but it hath its remote matter from meates of good digestion and quality, seasonably eaten after moderate exercise; but for that, one age is better than another, and one time of the yeare more convenient than another. For bloud is made more copiously in the Spring, because that season of the yeare comes neereſt to the temper of the bloud, by reason of which the bloud is rather to be thought temperate, than hot and moist, for that *Galen* makes the Spring temperate, and besides, at that time bloud-letting is performed with the best successe: youth is an age very fit for the generation of bloud; or by *Galen's* opinion, rather that part of life, that continues from the 25. to the 35. yeare of our age. Those in whom this humor hath the dominion, are beautified with a fresh and roſie colour, gentle and well natured, pleasant, merry, and facetious. The generation of Phlegme is not by the imbecillity of heat, as some of the ancients thought; who were perswaded that choler was caused by a raging, bloud by a moderate, and phlegme and melancholy, by a remiſſe heate. But that opinion is full of manifest errour: for if it be true that the *Chylus* is laboured and made into bloud in the same part, and by the same fire, that is, the liver; from whence in the same moment of time should proceed that strong and weak heate, seeing the whole masse of the bloud different in its foure essentiall parts, is perfected and made at the same time, and by the same equall temper of the same part, action, and bloud-making facultie; therefore from whence have we this varietie of humors? From hence, for that those meates by which wee are nourished, enjoy the like condition that our bodies doe, from the foure Elements, and the foure first qualities; for it is certaine, and wee may often observe in what kind soever they be united or joyned together, they retaine a certain hot portion imitating the Fire, another cold, the water; another dry, the earth, and lastly, another moist like to the Aire. Neither can you name any kinde of nourishment, how cold soever it be, not Lettuce it selfe, in which there is not some fiery force of heate. Therefore it is no marvell, if one and the same heate working upon the same matter of *Chylus*, varying with so great dissimilitude of substances, doe by its power produce so unlike humors, as from the hot, Choler; from the cold, Phlegme; and of the others, such as their finery of temper will permit.

Lib. I. de temp.

One and the same heate is the efficient cause of all humors at the same time.

The heate of the Sunne alone doth melt waxe and harden clay.

The divers condition of the matter alone, is the cause of varietie.

The effects of Phlegme.

There is no cause that any one should thinke that varietie of humors to be caused in us, rather by the diversity of the active heate, than waxe and a flint placed at the same time, and in the same situation of climate and soile, this to melt by the heat of the Sunne, and that scarce to waxe warme. Therefore that diversitie of effects is not to be attributed to the force of the efficient cause, that is, of heate, which is one and of one kinde in all of us; but rather to the materiall cause, seeing it is composed of the conflux, or meeting together of various substances, gives the heate leave to worke, as it were out of its store, which may make and produce from the hotter part thereof Choler, and of the colder, and more rebellious Phlegme. Yet I will not deny but that more Phlegme, or Choler may be bred in one and the same body, according to the quicker, or slower provocation of the heate; yet nevertheless it is not consequent, that the originall of Choler should be from a more acride, and of Phlegme from a more dull heat in the same man. Every one of us naturally have a simple heate, and of one kinde, which is the worker of diverse operations, not of it selfe, seeing it is alwayes the same, and like it selfe, but by the different fitnessse, pliability, or resistance of the matter on which it workes. Wherefore phlegme is generated in the same moment of time, in the fire of the same part, by the efficiency of the same heate, with the rest of the bloud, of the more cold, liquide, crude, and watery portion of the *Chylus*. Whereby it comes to passe, that it shewes an expresse figure of a certaine rude or unperfect bloud, for which occasion nature hath made it no peculiar receptacle, but would have it to run friendly with the bloud in the same passages of the veines, that any necessitie happening by famine, or indigency, and in defect of better nourishment, it may by a perfecter elaboration quickly assume the forme of bloud. Cold & rude nourishment make this humor to abound principally in winter, and in those which incline to old age, by reason of the similitude which phlegme hath with that season and age. It makes a man drowsie, dull, fat, and swollen up, and hasteneth gray haire. Choler

is as it were a certaine heate and fury of humors, which generated in the liver, together with the blood is carried by the veines and arteries through the whole body. That of it which abounds, is sent, partly into the guts, and partly into the bladder of the gall; or is consumed by transpiration, or sweates; It is somewhat probable that the Arteriall blood is made more thinne, hot, quicke and pallid, than the blood of the veines, by the commixture of this Alimentarie choler. This humor is chiefly bred and expeld in youth, and acrid and bitter meates give matter to it: but great labours of bodie and minde give the occasion. It maketh a man nimble, quicke, ready for all performance, leane, and quicke to anger, and also to concoct meates. The Melancholicke humor, or Melancholy, being the grosser portion of the blood, is partly sent from the Liver to the Spleene to nourish it, and partly carried by the vessels into the rest of the body, and spent in the nourishment of the parts endued with an earthly drinesse; it is made of meates of grosse juyce, and by the perturbations of the minde, turned to feare and sadnesse. It is augmented in Autumne, and in the first and crude old age; it makes men sad, harsh, constant, froward, envious and fearefull. All men ought to thinke, that such humors are wont to move at set houres of the day, as by a certaine peculiar motion or tide. Therefore the blood flowes from the ninth houre of the night, to the third houre of the day; then Choler to the ninth of the day; then Melancholy to the third of the night, the rest of the night that remaines, is under the dominion of Phlegme. Manifest examples hereof appeares in the French-Poxe. From the elaborate and absolute masse of the blood (as we said before) two kindes of humors, as excrements of the second concoction, are commonly and naturally separated, the one more grosse, the other more thinne. This is called either absolutely choler, or with an adjunct, yellow choler. That is called Melancholy, which drawne by the Spleene in a thinner portion, and elaborate by the heate of the Arteries, which in that part are both many and large, becomes nourishment to the part; the remnant thereof is carried by the veiny vessell into the orifice of the ventricle, whereby it may not cause, but whet the appetite, and by its astringent strengthen the actions thereof. But yellow Choler drawne into the bladder of the gall, remains there so long, till being troublesome, either in quantitie or qualitie, it is excluded into the guts, whereby it may cast forth the excrements residing in them; the expulsive faculcie being provoked by its acrimony, and by its bitternesse kills the wormes that are bred there. This same humor is accustomed to die the urine of a yellow colour. There is another serous humor, which truly is not fit to nourish, but profitable for many other things, which is not an excrement of the second, but of the first concoction. Therefore nature would that mixed with the *Chylus*, it should come to the Liver, and not be voided with the excrements, whereby it might alay the grossenesse of the blood, and serve it for a vehicle; for otherwise the blood could scarce passe through the capillary veines of the Liver, and passing the sinous and gibbous parts thereof, come to the hollow veine. Part of this serous humor separated together with the blood which serves for the nourishment of the Reines, and straight carried into the bladder, is turned into that urine which we daily make; the other part therefore carried through all the body together with the blood, performing the like duty of transportation, is excluded by sweats into which it degenerates. Besides the forenamed, the Arabians have mentioned foure other humors, which they terme Alimentary and secondary, as being the next matter of nourishment, as those foure the blood contains, the remote. They have given no name to the first kinde, but imagine it to be that humor, which hangs ready to fall like to little drops in the utmost orifices of the veines. They call the second kinde, * Dew; being that humor, which entred already into the substance of the part, doth moisten it. The third they call by a Barbarous name *Cambium*, which already put to the part to be nourished, is there fastened. The fourth named *Gluten*, or *Glew*, is onely the proper and substance-making humidity of the simular parts, not their substance. The distinction of the degrees of nutrition recited by *Galen* in his Bookes of Naturall faculties, answer in proportion to this distinction of humors. The first is, that the blood flow to the part that requires nourishment; then that being there arrived, it may be agglutinated; then lastly, that having lost its former forme of nourishment, it may be assimilated.

The effects of Choler.

The effects of Melancholy.

What motions are in each quarter of the body.

The Melancholy humor doth not cause, but whet the appetite.

A Serous or wheylike humor.

Secondary humors.

* Ros.

Those

Humors a-
gainst nature.

Those humors are against nature, which being corrupted, infect the body and the parts in which they are contained by the contagion of their corruption, retaining the names and titles of the humors, from whose perfection and nature they have revolted, they all grow hot by putrification, although they were formerly by their own nature cold. And they are corrupted, either in the veines onely, or within and without the veines; In the veines Bloud and Melancholy; but both without and within the veines, Choler and Phlegme. When bloud is corrupted in its thinner portion, it turnes into choler, when in its thicker, into Melancholy; for the bloud becomes faultie two manner of waies, either by the corruption of its proper substance by putrification, or by admixtion of another substance by infection. The Melancholy humor which is corrupted in the veines, is of three sorts: the 1. is of a Melancholy juice putrifying, and by the force of a strange heate, turned as it were into ashes, by which it becomes adust, acride and biting. The other ariseth from that Choler which resembles the yolkes of egges, which by adustion becomes lecke-coloured, then æruginous, or of a blewish greene, then red, and lastly blacke, which is the very worst kinde of Melancholy, hot, maligne, eating and exulcerating, and which is never seene or voided with safetie. The third comes from Phlegme putrifying in the veines, which first degenerates into false Phlegme, but straight by the strength of extraneous heate degenerates into Melancholy.

Into what
humors the
bloud when
it corrupts
doth degene-
rate.
The Melan-
choly humor
corrupted, is
of three kinds.

In the veines,
and is either

Acide and very crude, as which hath had none or very litle impressiō of heate, but that which it first had in the stomacke.

Salt, which is bred by the sweet, putrifying and adust, or mixture of adust and salt particles.

Phlegme not naturall
is bred, either

Waterish, as is that thinne moisture which distills from the braine by the nostrills.

Mucous, as when that waterish is thickened into filth by the helpe of some accidentall or small heate.

Glassie, or * *Albuminous*, resembling molten glassie, or rather the white of an egge, and is most cold.

Gypsea, or Plaster-like, which is concrete into the hardnesse and forme of chalke, as you may see in the joints of the fingers in a knotty goutte, or in inveterate distillations upon the Lungs.

or without
the veines,
and is of 4.
sorts, either

In the veines, as the * vitelline (like in consistence to the yolke of a raw egge) which the acrimony of strange heate breeds of yellow choler, which same in diseases altogether deadly, degenerates into greene, æruginous, and lastly into a blue, or colourlike that which is dried by woad.

Choler not naturall
is bred, either

Or in the capacite of
the upper belly as the
ventricle, and this is
of five kinds

The first is called *Porracea* or leek-coloured, resembling the juyce of a lecke in greenenesse.

The 2. *æruginesa*, or æruginous, like in colour to verdigreasse.

The 3. blewish, or woad-coloured, like the colour died by woad.

The 4. red, differing in this from bloud, whose colour it imitates, that it never cometh into knots, or clods like bloud.

The 5. very red, generated by the excessse of the former, which causeth burning feavers.

* *Albuminea*.

* *Vitellina*.

The

The kinds of such choler, are often cast forth by vomit in diseases, the strength of the disease being past; being troublesome to the parts through which they are evacuated, by their bitterneſſe, acrimony and biting.

The Signes of a Sanguine Person.

I thinke it manifest, because the matter and generation of flesh is principally from blood, that a man of a fleshy, dense, and solid habite of body, and full of a sweete and vaporous juice, is of a Sanguine complexion. And the same party hath a flourishing and roaſie colour in his face, tempered as with an equall mixture of white and red; of white, by reason of the skinned lying utmost; of red, because of the blood spread underneath the skinned; for alwayes such as the humor is, such is the colour in the face. In manners hee is courteous, gentle, easie to be spoken to, not altogether estranged from the love of women, of a lovely countenance and smoothe forehead, ſeldome angry, but taking all things in good part; for as the inclination of humors is, so also is the disposition of manners. But blood is thought the mildest of all humors, but the strong heate of the inward parts maketh him to eate and drinke freely. Their dreames are pleasant, they are troubled with diseases arising from blood, as frequent Phlegmons, and many Sanguine puſtles breaking through the skinned, much bleeding, and menſtruous fluxes. Wherefore they can well endure blood-letting, and delight in the moderate use of cold and drie things; and lastly, are offended by hot and moist things. They have a great and strong Pulse, and much urine in quantitie, but milde of qualitie, of an indifferent colour and substance.

Such as the humor is, such is the colour.

The manners and diseases of Sanguine persons.

The Signes of a Cholericke Person.

Cholericke men are of a pale or yellowish colour, of a leane, slender and rough habit of body, with faire veines and large Arteries, and a strong and quicke Pulse: their skinned being touched, feels hot, dry, hard, rough and harsh, with a pricking and acrid exhalation which breathes forth of their whole body. They cast forth much choler by ſtoole, vomite and urine. They are of a quicke and nimble wit, stout, hardy and sharpe vindicators of received injuries, liberall even to prodigalitie, and somewhat too desirous of glory. Their sleepe is light, and from which they are quickly waked; their dreames are fiery, burning, quicke and full of furie; they are delighted with meates and dringes which are somewhat more cold and moist, and are ſubject to Tertian and burning feavers, the Phrenſie, Jaundise, Inflammations, and other cholericke puſtles, the Laſke, Bloody fluxe, and bitterneſſe of the mouth.

Cholericke are not commonly fat.

The manners and diseases of Cholericke persons.

The Signes of a Phlegmaticke Person.

Those in whom Phlegme hath the dominion, are of a whitish coloured face, and sometimes livide and swollen, with their body fat, soft and cold to touch.

They are moleſted with Phlegmaticke diseases, as oedematous tumors, the Dropſie, Quotidian feavers, falling away of the haire, and catarrhes falling downe upon the Lungs, and the *Aspera Arteria*, or Wheaſon; they are of a ſlow capacitie, dull, ſlothfull, drouſie, they doe dreame of raines, ſnowes, floods, ſwimming, and ſuch like, that they often imagine themſelves overwhelmed with waters; they vomite up much waterie, and Phlegmaticke matter, or otherwiſe ſpit and evacuate it, and have a ſoft and moiſt tongue.

The manners and diseases of Phlegmaticke persons.

And they are troubled with a dogge-like hunger, if it at any time ſhould happen that their inſipide Phlegme become acide; and they are ſlow of digeſtion, by reaſon of which they have great ſtore of cold and Phlegmaticke humors, which if they be carried downe into the windings of the cholicke-gut, they cauſe murmuring and noiſe, and ſometimes the Cholicke.

From whence noiſe, or rumbling in the belly proceeds

For much wind is eaſily cauſed of ſuch like Phlegmatick excrements wrought upon by

by a small and weake heate, such as Phlegmaticke persons have, which by its naturall lightnesse is diversly carried through the turnings of the guts, and distends and swells them up, and whiles it strives for passage out, it causeth murmurings and noises in the belly, like winde breaking through narrow passages.

Signes of a Melancholike person.

Diseases familiar to Melancholy persons.

THe face of Melancholy persons is swart, their countenance cloudy and often cruell, their aspect is sad and froward; frequent Schirrhus, or hard swellings, tumors of the spleene, Hæmorrhoids, *Varices* (or swollen veines) *Quartaine* feavers, whether continuall or intermitting, *Quintaine*, *Sextaine*, and *Septimane* feavours; and to conclude, all such wandering feavers or agues set upon them. But when it happens the Melancholy humor is sharpened, either by adustion, or commixture of Choler, then Tetters, the blacke Morpew, the Cancer simple and ulcerated, the Leprous and filthy scabbe, sending forth certaine scaly and branlike excrescences, (being vulgarly called Saint *Maries* evill) and the Leprosie it selfe invades them: They have small veines and arteries, because coldnesse hath dominion over them, whose proper tie is to straiten, as the qualitie of heate is to dilate. But if at any time their veines seeme bigge, that largenesse is not by reason of the laudable blood, contained in them, but from much windinesse; by occasion whereof it is somewhat difficult to let them blood; not onely because that when the veine is opened, the blood flowes slowly forth, by reason of the cold slownesse of the humors; but much the rather, for that the veine doth not receive the impression of the Lancet, sliding this way and that way, by reason of the windinesse contained in it, and because that the harsh drinessse of the upper skinne, resists the edge of the instrument. Their bodies seeme cold and hard to the touch, and they are troubled with terrible dreames, for they are observed to seeme to see in the night Devils, Serpents, darke dens and caves, sepulchers, dead corpses, and many other such things full of horror, by reason of a blacke vapour, deversly moving and disturbing the Braine, which also wee see happens to those, * who feare the water, by reason of the biting of a mad dogge. You shall finde them froward, fraudulent, parsimonious, and covetous, even to basenesse, slow speakers, fearefull, sad, complainers, carefull, ingenious, lovers of solitarinesse, man-haters, obstinate maintainers of opinions once conceived, slow to anger, but angered not be pacified. But when Melancholy hath exceeded natures and its owne bounds, then by reason of putrefaction and inflammation all things appeare full of extreme fury and madnesse, so that they often cast themselves headlong downe from some high place, or are otherwise guilty of their owne death, with feare of which notwithstanding they are terrified.

From or by what their veines are swollen.

Their dreames

* *Hydrophobi.*

Their manners.

From whence the change of the native temper.

How one may become cholericke.

How melancholick.

How Phlegmaticke.

But we must note that changes of the native temperament, doe often happen in the course of a mans life, so that hee which a while agoe was Sanguine, may now bee Cholericke, Melancholick, or Phlegmatick; not truly by the changing of the blood into such humors, but by the mutation of Diet, and the course or vocation of life. For none of a Sanguine complexion but will prove Cholericke if he eate hot and drie meates, (as all like things are cherished and preserved by the use of their like, and contraries are destroyed by their contraries) and weary his body by violent exercises, and continuall labours; and if there be a suppression of Cholericke excrements, which before did freely flow, either by nature, or art. But whosoever feeds upon meates generating grosse blood, as Beefe, Venison, Hare, old Cheese, and all salt meates, he without all doubt sliding from his nature, will fall into a Melancholy temper; especially if to that manner of diet, he shall have a vocation full of cares, turmoiles, miseries, strong and much study, carefull thoughts and feares; and also if he sit much, wanting exercise, for so the inward heate as it were defrauded of its nourishment, faints, and growes dull, whereupon grosse and droisie humors abound in the body. To this also the cold and drie condition of the place, in which we live, doth conduce, and the suppression of the Melancholy humor accustomed to be evacuated by the Hæmorrhoides, courses, and stools.

But he acquires a Phlegmaricke temper whosoever useth cold & moist nourishment, much

much feeding, who before the former meate is gone out of the belly, shall stuffe his paunch with more, who presently after meate runs into violent exercises, who inhabite cold and moist places, who leade their life at ease in all idlenesse; and lastly, who suffer a suppression of the Phlegmaticke humour accustomely evacuated by vomite, cough, or blowing the nose, or any other way either by nature or arte. Certainly it is very convenient to know these things, that we may discern if any at the present be Phlegmaticke, Melancholicke or of any other temper, whether he be such by nature, or necessary. Having declared those things which concerne the nature of Temperaments, and deferred the description of the parts of the body to our Anatomy, we will begin to speake of the faculties governing this our life, when first we shall have shoven by a practicall demonstration of examples, the use and certainty of the aforesaid rules of Temperaments.

CHAP. VII.

Of the Practise of the aforesaid rules of Temperaments.

THat we may draw the Theoricke of the Temperaments into practise, it hath seemed good for avoyding of confusion, which might make this our Introduction seeme obscure, if we would prosecute the differences of the Temperaments of all men of all Nations, to take those Limits, which nature hath placed in the world; as South, North, East and West, and as it were the Center of those bounds, that the described variety of Tempers, in colour, habit, manners, studies, actions, and forme of life of men that inhabit those Regions scituated so farre distant one from another, may be as a sure rule, by which we may certainly judge of every mans temperature in particuler, as he shall appeare to be nearer, or further off from this, or that region. Those which inhabite the South as the Affricans, Æthiopians, Arabians and Egyptians, are for the most part deformed, leane, dusky coloured and pale, with blacke eyes and great lippes, curled haire, and a small and shrill voyce. Those which inhabite the Northren parts as the Scythians, Muscovites, Polonians and Germanes, have their faces of colour white, mixed with a convenient quantity of blood, their skin soft and delicate, their haire long, hanging downe and spreading abroad, and of a yellowish, or reddish colour; of stature they are commonly tall, & of a well proportioned, fat and compact habite of body, their eyes gray, their voyce strong, loud and bigge. But those who are scituated betweene these two former, as the Italians and French, have their faces somewhat swart, are well favoured, nimble, strong, hairy, slender, well in flesh, with their eyes resembling the colour of Goates-eyes, and often hollow eyed, having a cleere shrill and pleasing voyce.

The Southerne people are exceeded so much by the Northerne in strength and ability of body, as they surpass them in witt and the faculties of the minde. Hence is it you may reade in Histories, that the Scythians, Gothes and Vandals vexed Affricke and Spaine with infinite incursions, and most large and famous Empires have beene founded from the North to the South; but few or none from the South to the North. Therefore the Northren people thinking all right and law to consist in Armes, did by Duell onely determine all causes and controversies arising amongst the inhabitants, as wee may gather by the ancient lawes, and customes of the Lumbards, English, Burgonians, Danes and Germanes; and we may see in Saxo the Grammarian that such a law was once made by Fronto king of Denmarke. The which custome at this day is every where in force amongst the Muskovits. But the Southerne people have alwayes much abhorred that fashion, and have thought it more agreeable to Beasts than Men. Wherefore we never heard of any such thing used by the Assyrians, Egyptians, Persians or Iewes. But moved by the goodnes of their wit, they erected Kingdomes and Empires by the onely helpe of Learning and hidden sciences. For seeing by nature they are Melancholicke by reason of the drynesse of their temperature, they willingly addict themselves to

drinkers.

solitarineffe and contemplation, being endued with a singular sharpnesse of wit. Wherefore the *Æthiopians*, *Egyptians*, *Africans*, *Iewes*, *Phœnicians*, *Persians*, *Assyrians*, and *Indians*, have invented many curious sciences, revealed the Mysteries and secrets of Nature, digested the *Mathematiques* into order, observed the motions of the heavens, and first brought in the worship and religious sacrifices of the gods: Even so farre that the *Arabians* who live onely by stealth, and have onely a Waggon for their house, do boast that they have many things diligently and accurately observed in *Astrology* by their Ancestors, which every day made more accurate and copious, they, as by an hereditary right, commend to posterity, as it is recorded by *Leo* the *Africane*. But the Northern people, as the *Germanes*, by reason of the abundance of humours and blood, by which the minde is as it were oppressed, apply themselves to workes obvious to the senses, and which may be done by the hand. For their minds oppressed with the earthly masse of their bodies, are easily drawne from heaven and the contemplation of Celestiall things, to these inferior things, as to find out Mines by digging, to buy and cast mettals, to draw and hammer out workes of Iron, Steele and brasse. In which things they have proved so excellent, that the glory of the Invention of Guns and Printing belongs to them.

The people who inhabite the middle regions betweene these, are neither naturally fit for the more abstruse sciences, as the Southerne people are, nor for Mechanicke workes, as the Northern, but intermeddle with civil affaires, commerce and Merchandizing. But are endued with such strength of body as may suffice to avoid and delude the crafts and arts of the Southerne Inhabitants; and with such wisdom as may be sufficient to restrain the fury and violence of the Northern. How true this is, any one may understand by the example of the *Carthaginians* and *Africans*, who when they had held *Italy* for some yeares by their subtille counsels, crafty sleights and devices; yet could not escape but at the length their Arts being deluded, and they spoiled of all their fortunes, were brought in subjection to the Romans. The *Gothes*, *Hunnes* and other Northern people have spoiled & overrun the *Romane Empire* by many incursions and inroades, but destitute of counsell & providence, they could not keepe those things which they had gotten by Armes and valour. Therefore the opinion of all Historians is agreeing in this, that good lawes, the forme of governing a Commonwealth, all politicke ordinances, the Arts of disputing and speaking, have had their beginning from the *Greeks*, *Romans* and *French*. And from hence in times past and at this day a greater number of Writers, Lawyers and Counsellors of State have sprung up, than in all the world besides. Therefore that we may attribute their gifts to each Region, we affirme that, The Southerne people are borne and fit for the studies of learning; the Northern for warres, and those which be betweene them both for Empire and rule. The Italian is naturally wise, the Spaniard grave and constant; the French quicke and diligent, for you would say he runs when he goes, being compared to the slow and womanish pace of the Spaniard, which is the cause that Spaniards are delighted with French servants for their quicke agillity in dispatching busines. The Easterne people are specially endued with a good, firme and well tempered wit, not keeping their counsels secret and hid. For the haste is of the nature of the Sunne, and that part of the day which is next to the rising of the Sunne is counted the right-side and stronger; and verily in all living things the right side is alwayes the more strong and vigorous. But the Western people are more tender and effeminate, and more close in their carriage and minde, not easily making any one partaker of their secrets. For the West is, as it were subject to the Moone, because at the change it alwayes inclines to the West, wherby it happens, that it is reputed as no Æternall, sinister and opposite to the East; and the West is lesse temperate and wholesome. Therefore of the windes none is more wholesome than the Eastwinde which blowes from the west with a most fresh and healthfull gale, yet it feldome blowes, and but onely at Sun-set.

The Northern people are good eaters, but much better drinkers, witty when they are a litle moistened with wine, and talkers of things both to be spoken and concealed, not very constant in their promises and agreements, but principall keepers and preservers of shamefastnes and chastity, farre different from the inhabitants of the South, who

who are wonderfull sparing, sober, secret and subtle, and much addicted to all sorts of wicked Lust. *Aristotle* in his Problemes saith that those nations are barbarous and cruell, both which are burnt with immoderate heate, and which are oppressed with excessive cold, because a soft temper of the Heavens softens the Manners and the minde. Wherefore both, as well the Northerne, as Scythians and Germans; and the Southerne, as Africans are cruell; but these have this of a certaine naturall stourne, and souldierlike boldnes, and rather of anger, than a wilfull desire of revenge; because they cannot restrain by the power of reason the first violent motions of their anger by reason of the heat of their blood. But those of a certaine inbred and inhumane pravity of manners, wilfully and willingly premeditating they performe the workes of cruelty, because they are of a sad and melancholy nature. You may have an example of the Northerne cruelty from the Transilvanians against their seditious Captaine *George*, whom they gave to be torne in peeces alive and devoured by his Soldiers, (being kept fasting for three dayes before for that purpose) who was then unbowelled, and roasted, and so by them eaten up. The Cruelty of *Hannibal* the Captaine of the Carthaginians may suffice for an instance of the Southerne cruelty. He left the Romane Captives wearied with burdens and the length of the way, with the soles of their feet cut off; But those he brought into his tents, joyning brethren and kinsmen together he caused to fight, neither was satisfied with blood before he brought all the victors to one man. Also we may see the cruell nature of the Southerne Americans, who dip their children in the blood of their slaine enemies, then sucke their blood, and banquet with their broken and squeased Limbs.

who are to be counted Bar-
barous.

The Northerne
and Southerne
have each their
Cruelties.

Valer. Max.
lib. 9. cap. 2.

And as the Inhabitants of the South are free from divers Plethoricke diseases, which are caused by abundance of blood, to which the Northerne people are subject, as Feavers, Defluxions, Tumors, Madnesse with laughter which causeth those which have it to leape and dance (The people commonly terme it *S. vitus his Evill*) which admits of no remedy but Muticke: So they are often molested with the Frensie invading with madnesse and fury; by the heat whereof they are often so ravished and carried besides themselves that they foretell things to come; they are terrified with horrible dreames, and in their fits they speake in strange and forraigne tongues, but they are so subject to the scurfe and all kind of scabbs and to the Leprosie as their homebred disease, that no houses are so frequently mett withall by such as travell through either of the Mauritania's, as Hospitals provided for the Lodging of Lepers.

The diseases
of the Sou-
therne people.

Those who inhabit rough and Mountainous places, are more brutish, tough & able to endure labour: but such as dwell in plaines, especially if they be moorish, or fennish are of a tender body, and sweate much with a litle labour; the truth of which is confirmed by the Hollanders and Frizlanders. But if the plaine be such as is scorched by the heate of the Sunne, and blowne upon by much contrariety of windes, it breeds men who are turbulent, not to be tamed, desirous of sedition and novelty, stubborne, impatient of servitude, as may be perceived by the sole example of the inhabitants of Narbona province of France.

Mountainers.

Those who dwell in poore and barren places are commonly more witty and diligent and most patient of labours; the truth of which the famous witts of the Athenians, Ligurians and Romanes. and the plaine country of the Boeotians in Greece, of the Campanians in Italy, and of the rest of the inhabitors adjoyning to the Ligurian sea, approves.

CHAP. VIII.

Of the Faculties.

Faculty is a certaine power, and efficient cause, proceeding from the temperament of the part, and the performer of some actions of the body. There are three principall Faculties governing mans body as long as it enjoys its integrity;

What a faculty
is.
3. Faculties.

tegrity; the Animall, Virall and Naturall. The Animall is seated in the proper temperament of the Braine, from whence it is distributed by the Nerves into all parts of the body which have sense and motion. This is of three kinds, for one is Moving, another sensative; the third principall The sensative consists in the five externall senses, sight, hearing, taste, smell and touch. The Moving principally remaines in the Muscles and nerves, as the fit instruments of voluntary motion. The Principall comprehends the Reasoning faculty, the Memory and Fantasie. *Galen* would have the Common or inward sense to be comprehended within the compasse of the Fantasie, although *Aristotle* distinguisheth betweene them.

The triple use
of the Pulse.

The naturall
faculty is three-
fold.

What Nutri-
tion is.

Four other
faculties attend
upon the nour-
ishing faculty

The necessity
of the reten-
tive faculty.

Two excre-
ments of every
concoction.

The Vitall abides in the Hart, from whence heat and life is distributed by the Arteries to the whole body: this is principally hindered in the diseases of the Brest; as the Principall is, when any disease assailes the Braine; the prime action of the vitall faculty is Pulsation, and that continued agitation of the Heart and Arteries, which is of threefold use to the body: for by the dilatation of the Heart and Arteries the vitall spirit is cherished by the benefit of the Aire which is drawne in; by the contraction thereof the vapours of it are purged and sent forth, and the native heat of the whole body is tempered by them both.

The last is the Naturall faculty which hath chosen its principall seate in the Liver, it spreads or carries the nourishment over the whole body; but it is distinguished into 3. other faculties; The Generative which serves for the generation and forming of the Issue in the wombe; the Growing or increasing facultie which flourisheth from the time the Issue is formed, untill the perfect growth of the solid parts into their full dimensions of Length, height and breadth. The nourishing facultie which as servant to both the other repaires and repays the continuall efflux, and waste of the threefold substance; for Nutrition is nothing else but a replenishing, or repairing whatsoever is wasted or emptied This nourishing facultie endures from that time the Infant is formed in the wombe untill the end of life. It is a matter of great consequence in Physicke to know the 4 other faculties, which as servants attend upon the nourishing faculty; which are the Attractive, Retentive, Digestive, and Expulsive faculty. The Attractive drawes that juice which is fit to nourish the body, that I say which by application may be assimilated to the part. This is that faculty which in such as are hungry drawes downe the meat scarce chewed, and the drinke scarce tasted, into the gnawing and empty stomacke. The Retentive faculty is that which retaines the nourishment once attracted untill it be fully laboured and perfectly concocted; And by that meanes it yeelds no small assistance to the Digestive faculty. For the naturall heat cannot performe the office of concoction, unless the meat be embraced by the part, and make some stay therein. For otherwise the meate carryed into the stomacke never acquires the forme of *Chylus*, unless it stay detained in the wrinkles thereof, as in a rough passage, untill the full time of *Chylification*. The Digestive faculty assimilates the nourishment, being attracted and detained, into the substance of that part whose Faculty it is, by the force of the inbred heate & proper disposition or temper of the part. So the stomacke plainly changes all things which are eat and drunke into *Chylus*, & the Liver turnes the *Chylus* into blood. But the Bones & Nerves convert the red and liquid blood which is brought down unto them by the capillary or small veins, into a white & solid substance. Such concoction is far more laborious in a Bone and nerve, than in the Musculous flesh. For the blood being not much different from its nature, by a light change and concretion turnes into flesh. But this Concoction will never satisfie the desire of Nature and the parts, unless the nourishment purged from its excrements, put away the filth and drosse, which must never enter into the substance of the part. Wherefore there do not onely two sorts of excrements remaine of the first and second Concoction, the one thicke, the other thin, as we have said before; but also from the third Concoction which is performed in every part. The one of which we conceive onely by reason, being that which vanisheth into Aire by insensible Transpiration. The other is knowne sometimes by sweats, sometimes by a thicke fatty substance stayning the shirt; sometimes by the generation of haire and nailes, whose matter is from fuliginous and earthly excrements of the third Concoction. Wherefore the fourth Faculty was necessary which might yeeld no small helpe

helpe to nourishment; it is called the Expulsive, appointed to expell those superfluous excrements which by no action of heate, can obtaine the forme of the part. Such faculties serving for nutrition are in some parts two-fold; as some common, the benefit of which redounds to the whole body, as in the ventricle, liver & veines; Others onely attending the service of those parts in which they remaine, and in some parts all these 4. as well common as proper, are abiding and resident, as in those parts we now mentioned: some with the 4. proper have onely two common, as the Gall, Spleene, Kidnies and Bladder. Others are content onely with the proper, as the simular and Muscous parts, who if they want any of these 4. faculties, their health is decayed either by want of nourishment, an ulcer, or other wise. The like unnatural affects happen by the deficiency of just and laudable nourishment. But if it happen those faculties do rightly performe their duty, the nourishment is changed into the proper substance of the part, and is truly assimilated, as by these degrees. First it must flow to the part, then be joynted to it, then agglutinated, and lastly as we have said, assimilated. Now we must speake of the Actions which arise from the faculties.

The worke of the expulsive faculty.

By what degrees the nourishment is assimilated.

CHAP. IX.

Of the Actions.

AN Action or Function is an active motion proceeding from a faculty; for as the facultie depends on the Temperament, so the Action on the faculty, and the Act or worke depends upon the Action by a certaine order of consequence. But although that the words Actions and Act or worke are often confounded, yet there is this difference betweene them, as that the Action signifies the motion used in the performance of any thing; but the Act or worke, the thing already done and performed: for example, Nutrition and the Generating of flesh are naturall Actions; but the parts nourished, and a hollow ulcer filled with flesh are the workes of that motion, or action. Wherefore the Act ariseth from the Action, as the Action ariseth from the faculty, the integrity or perfection of the instruments concurring in both. For as, if the facultie be either defective, or hurt, no Action will be well performed: so unlesse the Instruments keepe their native and due conformitie (which is their perfect health, the operator of the Action proper to the instrument) none of those things, which ought to be, will be well performed. Therefore for the performance of blamelesse and perfect actions, it is fit a due conformity of the Instrument concur with the faculty. But Actions are two-fold; for they are either Naturall, or Voluntary. They are termed Naturall, because they are performed not by our will, but by their owne accord and against our will: As are that continuall motion of the Heart, the beating of the Arteries, the expulsion of the Excrements, and such other like which are done in us by the Law of Nature whether we will, or no. These Actions flow either from the Liver and veines, or from the Heart and Arteries. Wherefore we may comprehend them under the names of Naturall and Vitall Actions. For we must attribute his Action to each faculty, lest we may seeme to constitute an idle faculty, and no way profitable for use. The unvoluntary vitall actions are the dilatation & contraction of the Heart and Arteries, the which we comprehend under the sole name of the Pulse: by that they draw in, and by this they expell, or drive forth. The unvoluntary vitall actions be,

What an Action is,

An Action and an Act are different.

Natural Actions.

Generation } which proceed from the } Generative, }
Growth and } } Growing, and } facultie.
Nutrition } } Nourishing }

Generation is nothing else than a certaine producing, or acquiring of matter, and an introducing of a substantiall forme into that matter; this is performed by the assistance of 2. faculties; of the Altering which doth diversly prepare and dispose the seed and menstruous blood to put on the forme of a Bone, nerve, spleene, flesh and such

Generation what it is,

such like : of the Forming faculty which adorne with figure, site and composition, the matter ordered by so various a preparation.

What Growth is,

Growth is an enlarging of the solide parts into all the dimensions, the pristine and ancient forme remaining safe and sound in figure and solidity. For the perfection of every growth is judged onely by the solid parts; for if the body swell into a masse of flesh, or fat, it shall not therefore be said to be growne : but then onely when the solid parts doe in like manner increase, especially the bones, because the growth of the whole body followes their increase, even although at the same time it waxe leane, and pine away.

What Nutrition is,

Nutrition is a perfect assimilation of that nourishment which is digested, into the nature of the part which digests. It is performed by the assistance of 4. subsidiary or helping actions, Attractive, Retentive, Digestive and Expulsive.

Action voluntary,

* *Anima sensiens.*

The voluntary actions which we willingly performe, are so called, because we can at our pleasure hinder, stir up, slow or quicken them. They are three in generall, the sensitive, mooving, and principall Action. The sensitive * Soule comprehends all things in five senses, in Sight, Hearing, Smell, Taste and Touch. Three things must necessarily concur to the performance of them, the Organe, the *Medium* or meane, and the Object. The principall Organe, or Instrument, is the Animall spirit diffused by the nerves into each severall part of the body, by which such actions are performed. Wherefore for the present we will use the Parts themselves for their Organes. The Meane is a body, which carries the Object to the Instrument. The Object is a certaine externall quality, which hath power by a fit *Medium* or Meane to stirre up and alter the Organe. This will be more manifest by relating the particular functions of the senses by the necessary concurring of these three.

How sight is performed.

Sight, is an action of the seeing facultie, which is done by the Eye fitly composed of its coates and humors, and so consequently the Organically body of this Action. The Object is a visible quality brought to the Eye. But such an Object is two-fold; for either it is absolutely visible of its selfe, and by its owne Nature, as the Sun, the fire, the Moone and Starres : or desires as it were the helpe of another that it may be actually such, for so by the comming of light the colours, which were visible in power onely, being brought to the Eye doe seeme and appeare such as they actually are. But such Objects cannot arrive at the Eye, but thorough a cleere and illuminate *Medium*, as the Aire, Water, Glasse and all sorts of Cryshall.

How hearing.

The Hearing hath for its Organe the Eare and Auditory passage, which goes to the stony bone furnished with a Membrane investing it, an Auditory Nerve, and a certaine inward spirit there contained. The Object is every sound arising from the smitten or broken Aire, and the Collision of two bodies meeting together. The *Medium* is the encompassing Aire which carries the sound to the Eare.

How smelling

Smelling (according to *Galens* opinion) is performed in the Mamillary processes produced from the proper substance of the braine, and seated in the upper part of the nose : although others had rather smelling should be made in the very foremost ventricles of the braine. This Action is weake in man in comparison of other Creatures : the Object thereof is every smell, or fumide exhalation breathing out of bodies. The *Medium* by which the Object is carried to the noses of Men, Beasts and Birds, is the Aire, but to Fishes the Water it selfe. The Action of

How the taste

* *Sapor.*

taste is performed by the tongue being tempered well and according to nature, and furnished with a nerve spread over its upper part from the third and fourth conjugation of the Braine. The Object is * Taste, of whose nature and kindes we will treat more at large in our Antidotary. The *Medium* by which the Object is so carried to the Organ, that it may affect it, is either externall, or internall : The externall is that spittle which doth as it were anoynt and supple the tongue ; the internall is the Spongy flesh of the tongue it selfe, which affected with the quality of the Object doth presently so possesse the nerve that is implanted in it, that the kinde and quality thereof by the force of the spirit may be carryed into the common sense. All parts endued with a nerve enjoy the sense of touching, which is chiefly done, when a tractable quality doth

How touching.

penetrate

penetrate even to the true and nervous skinned, which lyeth under the Cuticle, or scarfe-skinned; we have formerly noted, that it is most exquisite in the skinned which invests the ends of the fingers. The Object is every tractable quality, whether it be of the first ranke of qualities, as Heate, Cold, Moisture, Drynesse, or of the second, as Roughnesse, Smoothnesse, Heavinessse, Lightnesse, Hardnesse, Softnesse, Rarity, Density, Friability, Vnctuosity, Grossenesse, Thinnesse. The *Medium* by whose procurement the instrument is affected, is either the skinned or the flesh interwoven with many Nerves.

The next Action, is that Motion, which by a peculiar name wee call voluntary; this is performed and accomplished by a Muscle, being the proper Instrument of voluntary Motion. Furthermore every motion of a member possessing a Muscle is made either by bending and contraction, or by extension. Although generally there be so many differences of voluntary motion, as there are kinds of site in place; therefore Motion is said to be made upward, downward, to the righthand, to the left, forward and backward; Hither are referred the many kinds of motions, which the infinite variety of Muscles produce in the body. Into this ranke of Voluntary Actions, comes Respiration, or breathing because it is done by the helpe of the Muscles; although it be chiefly to temper the heate of the Heart. For wee can make it more quicke, or slow as wee please, which are the conditions of a voluntary Motion.

Of action.

How Respiration may be, a voluntary motion.

Lastly, that wee may have somewhat in which wee may safely rest and defend our selves against the many questions which are commonly moved concerning this thing, we must hold, that Respiration is undergone and performed by the Animall faculty, but chiefly instituted for the vitall.

The Principall Action and prime amongst the Voluntary is absolutely divided in three, Imagination, Reasoning and Memory.

The third principall Action.

Imagination is a certaine expressing, and apprehension which discernes and distinguisheth betweene the formes and shapes of things sensible, or which are knowne by the senses.

Reasoning is a certaine judiciall estimation of conceived or apprehended formes or figures, by a mutuall collating, or comparing them together.

Memory is the sure storer of all things, and as it were the Treasure which the minde often unfolds and opens, the other faculties of the minde being idle and not employed. But because all the forementioned Actions whether they be Naturall, or Animall and voluntary, are done and performed by the helpe and assistance of the Spirits; Therefore now wee must speake of the Spirits.

CHAP. X.

Of the Spirits.

The spirit is a subtile and Aery substance, raised from the purer blood that it might be a vehicle for the faculties (by whose power the whole body is governed,) to all the parts, and the prime instrument for the performance of their office. For they being destitute of its sweet approach doe presently cease from action, and as dead do rest from their accustomed labours. From hence it is that making a variety of Spirits according to the number of the faculties, they have divided them into three; as one Animall, another Vitall, another Naturall.

What a spirit is,

Spirits threefold,

The Animall spirit,

The Animall hath taken his seate in the braine; for there it is prepared and made, that from thence conveyed by the Nerves it may impart the power of sense and Motion to all the rest of the members. An argument heereof is, that in the great Cold of Winter, whether by the intercepting them in their way, or by the concretion, or as it were freezing of those spirits,

the joynts grow stiffe, the hands numme, and all the other parts are dull, destitute of their accustomed agility of motion, and quicknesse of sense. It is called *Animall* not because it is the * Life, but the cheife and prime instrument thereof; wherefore it hath a most subtile and Aery substance: and enjoyes divers names according to the various condition of the Sensories or seates of the senses into which it enters; for that which causeth the sight, is named the Visive; you may see this by night, rubbing your eyes, as sparkling like fire. That which is conveyed to the Auditorie passage, is called the Auditive or Hearing; That which is carried to the Instruments of Touching, is termed the Tactive; and so of the rest.

How it is made. This Animall spirit is made and laboured in the windings and foldings of the veines and Arteries of the braine, of an exquisite subtile portion of the vitall brought thither by the *Carotida Arteria*, or sleepey Arteries, and sometimes also of the pure aire, or sweete vapour drawne in by the Nose in breathing. Hence it is, that with Ligatures we stoppe the passage of this spirit, from the parts we intend to cut off. An Humor which obstructs or stopps its passage, doth the like in Apoplexies and Palsies, whereby it happens that the members scituate under that place doe languish and seeme dead, sometimes destitute of motion, sometimes wanting both sense and motion.

The Vitall spirit. The Vitall spirit is next to it in dignitie and excellency, which hath its cheife mansion in the left ventricle of the Heart, from whence through the Channells of the Arteries it flowes into the whole body, to nourish the heate which resides fixed in the substance of each part, which would perish in short time unlesse it should be refreshed by heat flowing thither together with the spirit. And because it is the most subtile next to the Animall, Nature (lest it should vanish away) would have it contained in the Nervous coat of an Artery, which is five time more thicke, than the Coate of the veines, as *Galen*, out of *Herophilus*, hath recorded.

What the matter of it is. It is furnished with matter from the subtile exhalation of the blood, and that aire which we draw in breathing. Wherefore it doth easily and quickly perish by immoderate dissipations of the spirituous substance, and great evacuations; so it is easily corrupted by the putrifaction of Humors, or breathing in of pestilent aire and filthy vapours, which thing is the cause of the so suddaine death of those which are infected with the Plague. This spirit is often hindred from entering into some part by reason of obstruction, fulnesse, or great inflammations, whereby it followes that in a short space, by reason of the decay of the fixed and inbred heat, the parts doe easily fall into a Gangrene and become mortified.

There is some doubt of the Naturall spirit. The Naturall spirit (if such there be any) hath its station in the Liver and Veines. It is more grosse and dull than the other, and inferior to them in the dignitie of the Action, and the excellencie of the use. The use thereof is to helpe the concoction both of the whole body, as also of each severall part, and to carry blood and heate to them.

Fixed spirits. Besides those already mentioned, there are other spirits fixed and implanted in the simular and prime parts of the body, which also are naturall, and Natives of the same place in which they are seated and placed. And because they are also of an Aery and fiery nature, they are so joyned or rather united to the Native heate, that they can no more be separated from it, than flame from heate; wherefore they with these that flow to them are the principall Instruments of the Actions, which are performed in each severall part; And these fixed spirits have their nourishment and maintenance from the radicall and first bred moisture, which is of an Aery and oyle substance and is as it were the foundation of these Spirits and the inbred heat. Therefore without this moisture no man can live a moment. But also the Cheife Instruments of life are these Spirits together with the native heate. Wherefore this radicall Moisture being dissipated and wasted, (which is the seate, fodder and nourishment of the Spirits and heate) how can they any longer subsist and remaine? Therefore the consumption of the naturall heate followeth the decay of this sweet and substance-making moisture, and consequently death, which happens by the dissipating and resolving of naturall heate.

But

But since then these kinde of Spirits with the naturall heate, is contained in the substance of each simular part of our body (for otherwise it could not persist) it must necessarily follow, that there be as many kinds of fixed Spirits, as of simular parts. For because each part hath its proper temper and encrease, it hath also its proper spirit, and also its owne proper fixed and implanted heat, which heere hath its abode, as well as its Originall. Wherefore the spirit and heate which is seated in the bone, is different from that, which is impact into the substance of a Nerve, Veine or such other simular part; because the temper of these parts is different, as also the mixture of the Elements from which they first arose and sprung up. Neither is this contemplation of spirits of small account, for in these consist all the force and efficacy of our Nature.

These being by any chance dissipated or wasted, wee languish, neither is any health to be hoped for, the floure of life withering and decaying by little and little. Which thing ought to make us more diligent, to defend them against the continuall efflux of the threefold substance. For if they be decayed, there is left no proper Indication of curing the disease, so that we are often constrained, all other care laid aside, to betake our selves to the restoring and repaying the decayed powers. Which is done by meats of good juyce, easie to be concocted and distributed, good Wines and fragrant smells.

But sometimes these Spirits are not dissipated, but driven in and returned to their fountaines, and so both oppresse and are oppressed; whereupon it happens we are often forced to dilate and spread them abroad by binding and rubbing the parts. Hitherto wee have spoke of these things which are called Naturall, because we naturally consist of them; it remaines that we now say somewhat of their Adjuncts and associates by familiarity of Condition.

The use and necessity of the Spirits.

What the remedy for the dissipation of the Spirits.

What the remedy for oppression of the spirits is.

The Adjuncts and Associates to things Naturall, are

Age: of which, by reason of the similitude of the Argument, wee were constrained to speake when we handled the Temperatures.

Sexe.

Colour; of which we have already spoken.

The Conformation of the instrumentall parts;

Time, whose force we have also considered.

Region.

Order of Diet and Condition of life.

CHAP. XI.

Of the Adjuncts of things Naturall.

SExe is no other thing than the distinction of Male and Female, in which this is most observable, that for the parts of the body, and the fire of these parts, their is little difference betweene them; but the Female is colder than the Male. Wherefore their spermatieall parts are more cold, soft and moyst, and all there naturall actions lesse vigorous, and more depraved.

What sexe is.

The nature of weomen.

The Nature of Eunuches is to be referred to that of weomen, as who may seeme to have degenerated into a womanish nature, by deficiency of heate; their smooth body and soft and shrill voyce doe very much assimilate weomen. Notwithstanding you must consider that there be some Manly weomen, which their manly voyce and chinne covered with a little hairinesse doe argue; and on the contrary, there are some womanizing, or womanish men, which therefore we terme dainty and effeminate.

Of Eunuches.

Of Hermaphrodites.

Colour sheweth the wrapper of the Temperament

The Hermaphrodite as of a doubtfull nature and in the middle of both sexes seemes to participate of both Male and Female.

The Colour which is predominante in the habite and superficies of the body and lyes next under the skinne, shewes the temperament of what kinde soever it be; for as *Galen* notes in *Comment. ad Aphor. 2. sect. 1.* Such a colour appeares in us, as the contained humor hath. Wherefore if a rosie hew colour the cheekes, it is a signe the body abounds with blood, and that it is carryed abroad by the plenty of Spirits. But if the skinne be dyed with a yellow colour, it argues Choler, is predominante; if with a whitish and pallide hew, Phlegme; with a sable and dusky, Melancholy. So the colour of the excrements which are according to Nature is not of the least consideration. For thus, if an ulcer being broken send forth white matter, it argues the soundnesse of the part from whence it flowes; but if sanious or bloody, Greene, blackish, or of divers colours, it shewes the weaknes of the solide part, which could not assimilate by concoction the colour of the excrementitious humor. The like reason is of unnaturall Tumors; For, as the colour, so the Dominion of the Humor causing or accompanying the swelling commonly is.

The perfection of the organically parts consists in 4. things.

The Conformitie, and integrity of the Organically parts is considered by their figure, greatnesse, number, situation and mutuall connexion. Wee consider the figure, when wee say almost all the externall parts of the body are naturally round, not onely for shew, but for necessitie, that being smooth, and no way cornered, they should be lesse obnoxious to externall injuries; wee speake of Greatnesse, when wee say, some are large and thicke, some lancke and leane. But wee consider their number, when we observe some parts to abound, some to want, or nothing to be defective or wanting. Wee insinuate site and connexion when wee search, whether every thing be in its proper place, and whether they be decently fitted, and well joyned together.

We have handled the varyeties of the foure seasons of the yeare, when we treated of Temperaments. But the consideration of Region (because it hath the same judgment that the Aire) shall be referred to that disquisition, or enquiry which we intend to make of the Aire, amongst the Things not naturall.

Diet.

The Manner of life and order of Diet are to be diligently observed by us, because they have great power either to alter, or preserve the Temperament. But because they are of almost infinite variety, therefore they scarce seeme possible to fall into Arte, which may prosecute all the differences of Diet and vocations of life. Wherefore if the Calling of Life be laborious, as that of husbandmen, Marriners, and other such trades, it strengthens and dries the parts of the body. Although those which labour much about Waters, are most commonly troubled with cold and moyst diseases although they almost kill themselves with labour.

Againe, those which deale with Mettalls, as all sorts of Smithes, and those which cast and worke brasse, are more troubled with hotte diseases, as feavers. But if their Calling be such as they sit much, and worke all the day long sitting at home, as shoemakers; it makes the body tender, the flesh effeminate and causeth great quantity of excrements. A life as well idle and negligent in body, as quiet in minde, in all riotousnes and excesses of Dyet, doth the same. For from hence the body is made subject to the stone, gravell and Gout.

The common duties of an indifferent Diet.

That calling of life which is performed with moderate labour, clothing and dyet, seemes very fit and convenient to preserve the naturall temper of the body. The Ingenious Chirurgeon may frame more of himselfe that may more particularly conduce to the examination of these things. Therefore, the things naturall, and those which are neere or Neighbouring to them being thus briefly declared, the Order seemes to require that wee make enquiry of Things not Naturall.

CHAP. XII.

Of things not Naturall.

THe things which wee must now treat of, have by the latter Physitions beene termed, Not naturall; because they are not of the number of those which enter into the constitution, or composure of mans body; as the Elements, Humors, and all such things which we formerly comprehended vnder the name of Naturall: Although they be such as are necessary to preserve and defend the body already made and composed. Wherefore they were called by *Galen* Preservers, because by the due use of them the body is preserved in health. Also they may be called doubtfull; and Neuters, for that rightly and fitly used they keepe the body healthfull; but inconsiderately, they cause diseases. Whereby it comes to passe that they may be thought to pertaine to that part of Physicke which is of preserving health, not because some of these things should be absolutely and of their owne nature wholsome, and others unwholsome, but onely by this, that they are, or prove so by their convenient, or preposterous use. Therefore we consider the use of such like things from 4 conditions, quantitie, quality, occasion, and manner of using; if thou shalt observe these, thou shalt attaine and effect this, that those things which of themselves are as it were, doubtfull, shall bring certaine and undoubted health. For these 4. Circumstances doe so farre extend, that in them as in the perfection of Arte, the Rules which may be prescribed to preserve health are contained. But *Galen* in another place hath in 4. words comprehended these things not Naturall; as things Taken, Applied, Expelled, and to be Done. Things Taken are those which are put into the body, either by the mouth or any other way, as the Aire, meate and drinke. Things Applied are these which must touch the body, as the Aire now mentioned, affecting the body with a diverse touch of its qualities of heat, cold, moisture or drynesse. Expelled are, what things soever being unprofitable are generated in the body and require to be expelled. To be Done are labour, rest, sleepe, watching and the like. We may more distinctly and by expression of proper names revoke all these things to sixe; which are

Why they are called things not naturall.

Galen. 1. ad Glauconem.

1. de sanitat. tuenda.

Aire,
Meat and Drinke,
Labour and Rest,
Sleepe and Watching,
Repletion and Inanition, or things to be expelled, or retained and kept,
Perturbations of the Minde.

CHAP. XIII.

Of the Aire.

Aire is so necessary to life, that we cannot live a moment without it, if so be that breathing, and much more transpiration, be not to be separated from life. Wherefore it much conduceth to know, what Aire is wholsome, what unwholsome, and which by contrariety of qualities fights for the Patient against the disease; or on the contrary by a similitude of qualities shall nourish the disease, that if it may seeme to burden the Patient by increasing or adding to the disease, we may correct it by Arte. So in curing the wounds of the head, especially in Winter, we labour by all the means we may to make the aire warme. For cold is hurtfull to the Braine, Bones, and the wounds of these parts; and heat is comfortable and friendly. But also the aire being drawne into the body by breathing when it

How necessary for life the aire is.

is hotter than ordinarie, doth with a new warmth overheate the heart, lungs and spirits, and weaken the strength by the dissipation of the spirits too much attenuated; so being too cold, in like manner the strength of the faculties faints and growes dull, either by suppression of the vapours, or by the inspissation, or thickning of the spirits.

What Aire is
hurtfull,

Therefore to conclude, that Aire is to be esteemed healthfull, which is cleere, subtile, and pure, free and open on evcry side, and which is farre remote from all carrion-like smells of dead carcases, or the stench of any putrifying thing whatsoever: the which is farre distant from standing pooles, and fennes and caves, sending forth strong and ill vapours; neither too cloudy nor moist by the nearenesse of some river.

Such an Aire, I say, if it have a vernall temper, is good against all diseases. That aire which is contrary to this is altogether unhealthfull, as that which is putrid, shut up, and prest, by the straitnesse of neighbouring mountaines, infected with some noysome vapour. And because I cannot prosecute all the conditions of aires, fit for the expelling of all diseases, as which are almost infinite, it shall suffice here to have set downe, what we must understand by this word Aire.

Three things
are unders-
stood by the
name of the
aires

Physitions commonly use to understand three things, by the name of Aire; The present state of the Aire; The Region in which wee live; and the season of the yeare. Wee spoke of the last, when wee treated of Temperaments. Wherefore wee will now speake of the two former. The present state of the Aire, one while for some small time, is like the Spring, that is temperate; otherwhiles like the Summer, that is hot and drie; otherwhiles like the Winter, that is cold and moist; and sometimes like the Autumne which is unequall; and this last constitution of the Aire, is the cause of many diseases. When upon the same day, it is one while hot, another cold, we must expect Autumnaill diseases. These tempers and varieties of constitutions of the Aire, are chiefly and principally stirred up by the windes; as which being diffused over all the Aire, shew no small force by their sodaine change. Wherefore we will briefly touch their natures: That which blowes from the East, is called the Eastwinde, and is of a hot and drie nature, and therefore healthfull. But the Westerne winde is cold and moist, and therefore sickly. The South winde is hot and moist, the Author of putrifaction and putride diseases. The North winde is cold and drie, therefore healthy: wherefore it is thought, if it happen to blow in the dogge-dayes, that it makes the whole yeare healthfull, and purges and takes away the seedes of putrifaction, if any chance to be in the aire. But this description of the foure windes, is then onely thought to be true, if we consider the windes in their owne proper nature, which they borrow from these Regions, from which they first proceede. For otherwise they affect the aire quite contrarie, according to the disposition of the places over which they came, as snowie places, Seaes, Lakes, Rivers, Woods, or sandy plaines, from whence they may borrow new qualities, with which they may afterwards possesse the aire, and so consequently our bodies.

How the
windes ac-
quite other
faculties, than
they naturally
have.
The West-
winde of it
felte unwhol-
some.

Hence it is we have noted the Westerne winde unwholsome, and breeding diseases, by reason of the proper conditio[n] of the Region from whence it came; and such, that is cold and moist; the *Gasconies* finde it, truly to their so great harme, that it seldom blowes with them, but it brings some manifest and great harme, either to their bodies, or fruits of the earth. And yet the *Greekes*, and *Latines* are wont to commend it for healthfulness, more than the rest. But also the rising and setting of some more eminent stars, doe often cause such cold windes, that the whole aire is cooled, or infected with some other maligne qualitie. For vapours and exhalations are often raised by the force of the stars, from whence windes, cloudes, stormes, whirlwindes, lightnings, thunders, haile, snow, raine, earthquakes, inundations, and violent raging of the sea, have their original. The exact contemplation of which things, although it be proper to Astronomers, Cosmographers, and Geographers, yet *Hippocrates* could not omit it, but that he must speake something in his book *De aëre & aquis*, where he touches by the way, the description of the neighbouring Regions, and such as hee knew.

What force
stars have up-
on the aire,

From this force of the aire, either hurtfull, or helping in diseases, came that famous observation of *Guido* of Caulias, That wounds of the head are more difficult to cure at Paris, than at Avignon, and the plaine contrarie of wounds of the legges; for the

the aire of Paris compared to that of Avignon is cold and moist, wherefore hurt full and offensive to the wounds of the head. On the contrary, the same aire, because it obscures the spirits, incrassates the blood, condensates the humors, and makes them lesse fit for defluxions, makes the wounds of the legges more easie to be healed, by reason it hinders the course of the humors, by whose defluxion the cure is hindered. But it is manifest, that hot and drie places make a greater dissipation of the naturall heate, from whence the weakenesse of the powers; by which same reason the Inhabitants of such places doe not so well endure bloodletting; but more easily suffer purgations, though vehement, by reason of the contumacie of the humor, caused by drie-nesse. To conclude, the aire changes the constitutions of our bodies, either by its qualities, as if it be hotter, colder, moister, or drier; or by its matter, as if it be grosser, or more subtile than is fit, or corrupted by exhalations from the earth; or by a sodaine and unaccustomed alteration, which any man may prove, who makes a sodaine change out of a quiet aire into a stormy and troubled with many windes. But because, next to the aire, nothing is so necessary to nourish mans body, as meate and drinke, I will now beginne to speake of them both.

How the aire of Paris comes to be ill for wounds of the head, and good for those of the legges.

By what means the aire changes our bodies.

CHAP. XIII.

Of Meate and Drinke.

THat this our Treatise of meate and drinke may be more briefe and plaine, I have thought good to part it into these heads, as to consider the goodnesse and illnesse of both of them, their quantitie, qualitie, custom, delight, order, time, and to accommodate them all to the ages and seasons of the year. We judge of the goodnesse and pravity of meates and drinckes from the condition of the good or vicious humors, or juyce which they beget in us. For evill juyce causeth many diseases. As on the contrary, good juyce drives away all diseases from the body, except the fault happen from some other occasion, as from quantity, or too much excesse. Wherefore it is principally necessary, that those who will preserve their present health, and hinder the access of diseases, feede upon things of good nourishment and digestion, as are good wine, the yolkes of egges, good milke, wheaten bread well baked, the flesh of Capons, Pertridge, Thrushes, Larkes, Veale, Mutton, Kid, and such like other, which you may finde mentioned in the Bookes which *Galen* writ *de Alimentorum facultatibus*; where also he examines those which are of evill juyce by their manifest qualities, as acrimony, bitternesse, saltnesse, aciditie, harshnesse and such like.

The goodnesse of nourishments.

But unlesse we use a convenient quantitie and measure in our meates, howsoever laudable they be, we shal never reape these fruits of health we hoped for. For they yeild matter of diseases, by the onely excesse of their quantitie; but wee may by this know the force of quantitie on both parts, because often the poisonous quality of meates of ill nourishment doth not hurt, by reason they were not taken into the body into a great quantitie. That measure of quantitie is chiefly to be regarded in diseases: for as *Hippocrates* saith, if any give meate to one sick of a feaver, he gives strength to the well, and increases the disease to the sicke, especially if he doe not use a meane. Wherefore it is a thing of no small consequence, to know what diseases require a slender and what a large diet, of which thing there is large relation made in our Section of the Aphorismes of *Hippocrates*; where he teacheth, the sicke must feed more largely in the beginnings of long diseases, wherby they may be enabled to indure the length of the disease, and last to the state thereof. But in sharpe and violent diseases, which presently come to their height, wee must use a slender diet; but most slender, when the disease is in the height; and besides, all our consultations in this kinde, must be referred to the strength of the patients. But those who enjoy their perfect health, must use a quantitie of meate, agreeable to their evacuation and transpiration; for men by reason of the strength of their heate, and the more copious dissipation of the triple substance, have greater appetite, than women; altogether by the same reason, that young people, and such

Their quantitie.

The quantitie of meates must be esteemed, according to the nature of the disease, and strength of the Patient.

such as grow, need more frequent and plentiful nourishment, than old men; and also amongst young men of the like age, some doe rightly require more copious nourishment than othersome, that is, according to the quantitie of their evacuations and custome. Certainly for gluttony, it is such as may be extended to all; but we all should take so much meate and drinke, that our powers may be refreshed and not oppressed: for by the decree of *Hippocrates*, these be the two compendiary wayes of preserving health; not to be over-filled with meate, and to be quicke to worke; and thus much of the quantity of meates. Neither must these who are either sound, or sicke, have lesse regard to the qualities of their meates; and those are either the first, as heating, cooling, moistening, drying; or the second, attenuating, incrassating, obstructing, opening, or some other like, working according to the condition of their nature. The manner of our diet is not onely to be framed according to these, but also to be varied; for the present state of such as be in health, requires to be preserved by the use of like things. As hot and moist nourishment is to be prescribed to children, as to those which are hot and moist: and cold, and drie, to old men, as to those who are cold and drie; if so be that vulgar saying be true, that, Health delights in the use of like things. Yet because old age how greene and new begun howsoever it be, is of it selfe as it were, a disease, it seemes to be more convenient, both to truth and for health, that old people should eat meates contrary to their nature, that is, hot, and moist, that so wee may deferre as much as we can, the causes of death, cold and driness, which hasten the destruction of that age. For wee must resist diseases by the use of their contraries, as those things which are contrary to nature. For otherwise, as much meate as you give to the sicke, you adde so much strength to the disease. And the same is the cause why *Hippocrates* said, that a moist diet is convenient for all such as are sicke of feavers, because a feaver is a drie distemperature. Therefore wee must diligently prie into the nature of the disease, that knowing it, wee may endeavour to abate its fury by the use of contraries.

The qualities
of meate.

Old age is a
disease.

Aphor. 16.
sect. 1.

The force of
Custome.

Aphor. 91.
sect. 2.

Aphor. 38.
sect. 2.

Accustomed
meates are
more grate-
full, and so by
that meane
more nourish-
ing.

But if custome (as they say) be another nature, the Physition must have a great care of it, both in sound and sicke. For this sometimes by little and little and insensibly, changes our naturall temperament, and instead thereof gives us a borrowed temper. Wherefore if any would presently or sodainely change a custome which is sometimes ill, into a better, truly hee will bring more harme, than good; because all sodaine changes (according the opinion of *Hippocrates*) are dangerous. Wherefore if necessitie require, that we should withdraw any thing from our custome, we must doe it by little and little, that so nature may by degrees be accustomed to contraries without violence, or the disturbance of its usuall government. For that meate and drinke which is somewhat worse, but more pleasant and familiar by custome, is to be preferred (in *Hippocrates* opinion) before better, but lesse pleasant and accustomed. Hence is it, that Countrey-men doe very well digest Beefe and Bacon, which commonly they use; but will turne into nidorulent vapours, Partridge, Capons, and other meate of good nourishment, sooner than change them into good and laudable *Chylus*. The cause of which thing is not onely to be attributed unto the propertie of their stronger, and as it were burning heate, but much more to custome, which by a certaine kinde of familiarity, causeth that meates of hard digestion are easily turned into laudable blood. For the force of custome is so great, that accustomed meates are more acceptable; whereby it comes to passe, that while the stomacke delights in them, it more streightly embraces them, and happily digests them, without any trouble of loathing, vomiting, or heaviness. All the contrary meete and happen in the use of meates which are unpleasant to the taste and stomacke. For the ventricle abhorring those things, makes manifest how it is troubled by its acide and nidorulent belchings, loathing, nauseousnesse, vomite, heaviness, paine of the head, and trouble of the whole body.

Wherefore we must diligently enquire, what meates the Patient chiefly delighted in, that by offering them, his appetite languishing by reason of some great evacuation, vomit, or the like, may be stirred up. For it will be better and more readily restored by things acceptable, though they be somewhat worse, as we noted a little before out of *Hippocrates*. By which words hee plainly taught, that it is the part of a good

good and prudent Physitian to subscribe to, and please the palate of his patient.

But seeing that order is most beautifull in all things, it is truly very necessary in eating our meate: for how laudable soever the meates bee in their quantity and quality, howsoever familiar by use, and gratefull by custome, yet unlesse they be eaten in due order, they will either trouble or molest the stomacke, or be ill, or slowly and difficultly concocted; wherefore we must diligently observe, what meates must be eaten at the first, and what at the second course; for those meates which be hard to concoct, are not to be eaten before those which are easy of digestion; neither drie and astringent things, before moistening and loosing.

The order of eating our meats.

But on the contrary, all slippery, fat, and liquid things, and which are quickly changed ought to goe before, that so the belly may be moistened; and then astringent things must follow, that the stomacke, by their helpe, being shut, and drawne together, may more straitly comprehend the meate on every side, and better performe the Chylification by its proper heate united and joyned together.

We must begin our meales with moist or liquid meat.

For this cause *Hippocrates Lib. de victu in acutis*, commands those things to be alwayes eaten in the morning, which are fit to loosen the belly, and in the evenings such as nourish the body. Yet notwithstanding drinke ought not to preceede, or goe before meate, but on the contrary meate must preceede drinke, by the order prescribed by him.

Whether ought wee in our eating to have lesse care of the time, than wee have of the order: for the time of eating of such as are healthfull, ought to be certaine and fixt; for at the accustomed houre, and when hunger presses, any sound man, and which is at his owne disposure may eat, but exercise and accustomed laboures ought to goe before; for it is fit, according to the precept of *Hippocrates*, that labour preceed meate, whereby the excrements of the third concoction may be evacuated, the native heate encreased, and the solid parts confirmed and strengthened, which are three commodities of exercise very necessary to the convenient taking of meate. But in sicke persons we can scarce attend, and give heed to these circumstance of time, and accustomed houre of feeding; for that indication of giving meate to the sicke, is the best of all, which is drawne from the motion of the disease, and the declining of the fit: for if you give meate in feavers, specially the fit then taking the Patient, you nourish not him, but the disease. For the meate then eaten, is corrupted in the stomacke, and yeelds fit matter for the disease. For meate (as we noted before out of *Hippocrates*) is strength to the sound, and a disease to the sicke, unlesse it be eaten at convenient time, and diligent care be had of the strength of the Patient, and greatness of the disease.

The time of eating.

The profit of labour before meate.

But neither is it convenient that the meate should be simple, and of one kinde, but of many sorts, and of divers dishes dressed after different formes, lest nature by the continuall and hatefull feeding upon the same meate, may at the length loath it, and so neither straitly containe it, nor well digest it; or the stomacke accustomed to one meate, taking any loathing thereat, may abhorre all other: and as there is no desire of that we doe not know, so the dejected appetite cannot be delighted and stirred up, with the pleasure of any meate which can be offered. For wee must not credit those superstitious, or too nice Physitions, who thinke the digestion is hindered by the much varietie of meates.

We must not give meat in a fit of a Fever.

The matter is farre otherwise, for by the pleasure of what things soever the stomacke allured doth require, it embraces them more straitly, and concocts them more perfectly. And our nature is desirous of varietie.

Variety of meats.

Moreover, seeing our body is composed of a solid, moist, and airy substance, and it may happen, that by so many laboures, which we are compelled to undergoe, and sustaine in this life, one of these may suffer a greater dissipation and losse than another; therefore the stomacke is necessarily compelled to seeke more varietie, lest any thing should be wanting to repaire that which is wasted. But also the age and season of the year, yeeld Indications of feeding, for some things are convenient for a young man, some for an old, some in Summer, some in Winter. Wherefore wee ought to know what befits each age and season. Children need hot, moist, and much nourishment, which may not onely suffice to nourish, but encrease the body. Wherefore

Why varietie of meats is good.

Indications of feeding, taken from the age.

fore we ought to know what befits each age and season. Children need hot, moist, and much nourishment, which may not onely suffice to nourish, but encrease the body. Wherefore they worst endure fasting, and of them, especially those who are the most lively and spiritfull. With old men it is otherwise, for because their heate is small, they neede little nourishment, and are extinguished by much. Wherefore old men easily endure to fast, they ought to be nourished with hot and moist meates, by which their solid parts, now growing cold and drie, may be heated and moistened, as by the sweet nourishment of such like meates. Middle aged men delight in the moderate use of contraries to temper the excesse of their too acride heate. Young people as temperate are to be preserved by the use of like things.

Indication
from the time
of the year.

The manner of diet in Winter must be hot and inclining to drinesse. Wherefore then we may more plentifully use roast-meates, strong wines and spices; because in the Winter season we are troubled with the cold and moist aire, and at the same time, have much heate inwardly; for the inner parts, according to *Hippocrates*, are naturally most hot in the Winter and the Spring, but feaverish in Summer; so the heat of Summer is to be tempered by the use of cold and moist things, and much drinke. In the temperate Spring all things must be moderate; but in Autumne, by little and little, we must passe from our Summer, to our Winter diet.

CHAP. XV.

Of Motion and Rest.

What motion
signifies.

Here Physitians admonish us, that by the name of Motion, we must understand all sorts of exercises, as walking, leaping, running, riding, playing at tennis, carrying a burden, and the like. Friction or rubbing is of this kinde, which in times past was in great use and esteeme, neither at this day is it altogether neglected by Physitians. They mention many kinds of it, but they may be all reduced to three, as one gentle, another hard, a third indifferent; and that of the whole body, or onely of some part thereof. The friction is called hard, which is made by the rough, or strong pressure of the hands, sponges, or a course and new linnen cloth: it drawes together, condensates, bindes and hardens the flesh, yet if it bee often and long used, at length it rarifies, dissolves, attenuates and diminishes the flesh, and any other substance of the body; and also it causeth revulsion, and drawes the defluxion of humors from one part to another. The gentle friction which is performed by the light rubbing of the hand, and such like, doth the contrarie, as softens, relaxes, and makes the skinn smooth and unwrinkled, yet unlesse it be long continued it doth none of these, worthy to be spoken of. The indifferent kinds consisting in the meane betwixt the other two, increaseth the flesh, swells or puffes up the habite of the body, because it retaines the bloud and spirits which it drawes and suffers them not to be dissipated.

The use of
exercises.

The benefit of exercise is great, for it increaseth naturall heate, whereby better digestion followes, and by that meanes nourishment, and the expulsion of the excrements, and lastly, a quicker motion of the spirits, to performe their offices in the bodie, all the wayes and passages being cleansed. Besides, it strengthens the respiration, and the other actions of the body, confirms the habite, and all the limbes of the body, by the mutuall attrition of the one with the other; whereby it comes to passe they are not so quickly wearied with labour. Hence we see that Country people are not to be tired with labour.

What the fit
rest time for
exercise.

If any will reape these benefits by exercise, it is necessary that he take opportunity to beginne his exercise, and that he seasonably desist from it, not exercising himselfe violently and without discretion; but at certaine times according to reason.

Wherefore the best time for exercise will be before meate (that the appetite may be encreased by augmenting the naturall heate) all the excrements being evacuated, lest nature being hungry and empty, doe draw and infuse the ill humors contained in the guts, and other parts of the body, into the whole habite, the liver, and other

noble

noble parts. Neither is it fit presently, after meate, to runne into exercise, lest the crude humors and meats not well concocted be carried into the veines. The measure and bounds of exercise must be, when the body appeares more full, the face looks red, sweat beginnes to breake forth, we breathe more strongly and quicke, and begin to grow weary; if any continue exercise longer, stiffness, and weariness affayles his joints, and the body flowing with sweate suffers a losse of the spiruous and humid substance which is not easily repaired; by which it becomes more cold, and leane even to deformitie.

The qualitie of exercise which we require, is in the midst of exercise, so that the exercise must be neither too slow and idle, neither too strong, nor too weake, neither too hasty, nor remisse, but which may move all the members alike. Such exercise is very fit for sound bodies. But if they be distempered, that sort of exercise is to be made choise of, which by the qualitie of its excess, may correct the distemper of the body, and reduce it to a certaine mediocritie. Wherefore such men as are stuffed with cold, grosse, and viscous humors, shall hold that kinde of exercise most fit for them, which is more laborious, vehement, strong, and longer continued. Yet so, that they doe not enter into it before the first and second concoction, which they may know by the yellownesse of their urine. But let such as abound with thinne and cholericke humors chuse gentle exercises, and such as are free from contention, not expecting the finishing of the second concoction, for the more acride heate of the solid parts delights in such halfe concocted juices, which otherwise it would so burne up, all the glutinous substance thereof being wasted, that they could not be adjoynded, or fastened to the parts. For the repeating, or renewing of exercise, the body should bee so often exercised, as there is a desire to eate. For exercise stirres up and revives the heate which lies buried and hid in the body: For digestion cannot be well performed by a sluggish heate; neither have we any benefit by the meate we eate, unlesse wee use exercise before.

The qualitie of exercise.

For whom strong exercises are convenient.

The last part of exercise begun and performed according to reason, is named * the *ordering of the body*, which is performed by an indifferent rubbing, and drying of the members; that so the sweat breake forth, the filth of the body, and such excrements lying under the skinne, may be allured and drawne out; and also that the members may be freed from stiffness and weariness. At this time it is commonly used by such as play at tennis.

* *Amo Deg-mia.*

But, as many and great commodities arise from exercise conveniently begunne and performed, so great harme proceeds of idleness; for grosse and vicious juyces heaped up in the body commonly produce crudities, obstructions, stones both in the reines and bladder, the Goute, Apoplexie, and a thousand other diseases.

What discommodities proceed from idleness.

CHAP. XVI.

Of Sleepe and Watching.

THat this our speech of Sleepe and Watching, which we now intend, may be more plaine, we will briefly declare, what commoditie or discommoditie they bring, what time and what houre is convenient for both, what the manner of lying must bee, and the choise thereof; what the dreames in sleeping, and what paines or heaviness and cheerefulness after sleepe may portend.

Sleepe is nothing else than the rest of the whole body, and the cessation of the Animall facultie from sense and motion. Sleepe is caused, when the substance of the braine is possessed, and after some sort overcome and dulled by a certaine vaporous, sweete and delightfome humidity; or when the spirits almost exhaust by performance of some labour, cannot any longer sustaine the weight of the body, but cause rest by a necessary consequence, by which meanes nature may produce other from the meate by concoction turned into blood.

What sleepe is.

Sleepe

The use of
Sleepe.

Sleepe fitly taken much helps the digestion of the parts, because in the time of rest, the heat, being the worker of all concoction, is carryed backe to them, together with the spirits. Neither doth sleepe only give ease to the wearyed members, but also lessens our cares and makes us to forget our labours.

Fit time for
Sleepe and the
nature of the
night.

The night is a fit time to sleepe and to take our rest in, as inviting sleepe by its moisture, silence and darknesse. For the Heat and Spirits in the thick obscurity of night, are driven in and retained in the center of the body; as on the contrary by the daily and as it were friendly and familiar light of the Sun, they are allured & drawne forth into the superficies, and outward part of the body; from whence they leave sleeping and begin to wake. Besides also, which makes not a little, to that opportunity and benefit which wee looke for from sleepe, the night season suffices for the worke of just and perfect concoction. Which is one reason amongst many that sleep on the day time may be hurtfull. For wee are wakened from our sleepe by the heat and spirits called forth to the skinn either by the light, or noise on the day time, before that the concoction which was begun be finished. But that sleepe cannot but be light which comes without necessity of sleeping. Wherefore the concoction being attempted, but not perfected, the stomacke is filled with crudities, distended with acide or soure belchings, and the braine troubled with grosse vapours and excrementitious humidities. From whence proceeds paine and heavines of the head, and store of cold diseases. But although sleepe on the night time be wholesome, yet it is fit, that it be restrained within the limits of an indifferent time. For that which exceeds hinders the evacuation of excrements both upwards and downewards: but in the meane time the heate which is neuer idle, drawes from them some portion or vapour into the veines, principall parts and habite of the body, to become matter for some disease. We must measure this time, not by the space of houres, but by the finishing the worke of concoction, which is performed in some, sooner than in other some. Yet that which is longest is perfected and done in seaven, or eight houres. The ventricle subsiding and falling into its selfe and its proper coats, and the urine tintured yeallow, gives perfect judgment thereof. For on the contrary the extension of the stomacke, acide belching, paine of the head, and heavines of the whole body, shew that the concoction is unperfect.

Sleepe on the
day-time.

There ought
to be a moderate
ration of our
nights sleepe.

How to be
knowne.

What the
forme and site
of our body
ought to be
while we sleep

In sleeping we must have speciall care of our lying downe, for first we must lye on our right side, that so the meat may fall into the bottome of our stomacke, which being fleshy and lesse membranous, is the hotter, and more powerfull to assimilate. Then a litle after we must turne upon our left side, that so the Liver with its Lobes, as with hands may on every side embrace the ventricle, and as fire put under a Kettle, hasten the concoction. Lastly, towards morning it will not be unprofitable to turne againe upon our right side, that by this scituation the mouth of the stomacke being opened, the vapours which arise from the elixation of the *Chylus* may have freer passage. Lying upon the backe is wholly to be avoided; for from hence the Reines are inflamed, the Stone is bred, Palsies, Convulsion, and all diseases which have their originall from the defluxion into the spinall marrow, and to the Nerves taking beginning from thence. To lye upon the belly is not unprofitable for such as have used to lye so, if they be not troubled with defluxions into the eyes; for so the humor will more easily flow into the part affected. But thus the worke of concoction is not a litle furthered, because by that forme of lying, not onely the inward heate is contained and gathered together about the ventricle, but the encompassing warmnesse of the soft feathers of the bed, aides and assists it.

The harme of
lying on our
backes.

Upon our bel-
lies.

The consider-
ation of
dreames.

Neither are the Dreames which we have in our sleepe to be neglected, for by the diligent consideration of these, the affections and superfluous humors which have chiefe power in the body are marvailously knowne. For those who have raging Choler running up and downe their bodyes while they sleepe, all things to them appeare bright, shining, fiery, burning, full of noyse and contention. Those who abound with Phlegme dreame of floods, shewes, showers and inundations and falling from high places. Those who are Melancholy dreame of gapings and gulfes in the earth, thicke and obscure darknesse, smokes, caves, and all blacke and dismall things. But those whose bodyes abound in blood dreame of marriages, dances, embracing

bracings of women, feasts, jests, laughter, of orchards and gardens; and to conclude, of all things pleasant and splendid.

Also we must observe how the Patient doth after sleepe, whether more lively and cheerefull, or more heavy, for by the opinion of *Hippocrates*,

*Cum labor à sommo est, lethalem collige morbum :
Sin profit somnus, nihil hinc lethale timendum est.*

Aphor. I. sect.
2.

Paine sleepe ensuing, an ill disease doth show :
But if sleepe profit bring, no harme from thence will flow.

And as sleepe so watching, if it exceede measure, is hurtfull; for it hurts the temperance of the braine, weakens the senses, wastes the spirits, breeds crudities, heavinesse of the head, falling away of the flesh, and leanenesse over all the body, and to conclude, it makes ulcers more dry, and so consequently rebellious, difficult to heale, and maligne. There are many other things may be spoken of sleepe and watching, but these may suffice a Chirurgion.

CHAP. XVII.

Of Repletion, and Inanition, or Emptinesse.

Here are, to bee short, two sorts of Repletion, or of all excesse; one is of a simple qualitie, without any defluxion, or societie of any humor, as appeares in distempers without matter: the other is of quantitie and masse, the body being distended with too much meate, or too great quantitie of humors; from whence proceed an infinite number of diseases. They call the Repletion of meates, satietie or fulnesse, and it is of two kinds; the one which is called * Repletion or Fulnesse to the vessels; the other * Repletion to the strength.

The kinds of
Repletions
or rather of
Excesses,

* Re-
ple- { ad vasa
tio { ad vires

Wee judge of satietie to the vessels, by the distention and swelling of the veines and intrailles, as the stomacke. Wee call satietie to the strength, when the body is loaded with more meates, than it can well beare. But also there is a double Repletion of humors. For either it is of some one humor, or of all the humors; they call this by a peculiar name *Plethora*. For *Galen* defines *Plethora* an equall excesse of all the humors. For if at any time he define a *Plethora* to be an excesse of bloud onely, then verily by the name of bloud, he understands an equall comprehension of the foure humors; as it is taught in Physicke schooles.

Gal. Meth. 13.
cap. 6.

The Repletion which is caused by some one humor, is termed by *Galen* in the place before mentioned, *Cacoehymia*, (that is, an evill juyce) whether the Repletion proceede of a Cholericke, Melancholicke, Phlegmaticke, or serous humor.

What Caco-
ehymia.

Now Inanition, or evacuation is no other thing than the expulsion, or effusion, of humors which are troublesome, either in quantitie, or qualitie. Of evacuations, some are universall, which expell superfluous humors from the whole body; such are purging, vomiting, transpiration, sweats, phlebotomie. Some particular which are performed onely to evacuate some part, as the braine by the nose, palate, eyes, eares; the lungs by the weazon; the stomacke by vomite and stoole, the guts by stoole, the liver and the spleene by urine and ordure. These evacuations are sometimes performed by nature, freeing it selfe of that which is troublesome to it; otherwhiles by the Art of the Physicion in imitation of nature.

The kinds of
evacuation. 8

And againe, one of these is good and requisite, when onely the humor which is hurtfull, either in quantitie or qualitie, is evacuated; The other not requisite, or

immoderate, when the profitable humors together with the unprofitable, are expelled.

The commodities of moderate scratching.

But what evacuations soever these be, they are performed and done, either by the scratching and rubbing of the skinne, as when a cholericke, salt, or serous humor, or some windinesse lying betwene the skinne and the flesh, cause itching. For by scratching the skinne, it gets passage out, which is manifest by the efflux of a serous matter burning, or causing scabbs and ulcers, if the humor be somewhat grosse, but insensible and not so manifest, if it be windinesse, the skinne by that rubbing being rarefied, and the grosse flatulency attenuated. Wherefore they doe ill who hinder their Patients from scratching, unlesse they scratch so cruelly and hard, that there may bee danger, (by reason of the great heate and paine thereby caused) of some defluxion or falling downe of humors into the part.

The force of vomits.

Salivation.

The whole body is also purged by urines.

Or these evacuations are performed by much matter evacuated from an opened Bile, or running ulcer, a Fistula, or such like sores. Or by sweats which are very good and healthfull, especially in sharpe diseases, if they proceede from the whole body, and happen on the criticall dayes. By vomit, which often violently drawes these humors from the whole body, even from the utmost joints, which purging medicins could not evacuate, as wee may see in the Palsie, and Sciatica, or Hip-goute. By spitting, as in all who are suppurated either in the sides or lungs. By Salivation, or a Flegmaticke fluxe by the mouth, as in those who are troubled with the French Pockes. By sneezing and blowing the nose; for by these the braine oppressed with moisture, disburdeneth its selfe, whether it be done without, or with the helpe of sternutatories and errhines; wherefore children, and such as have somewhat moist braines purge themselves often this way. By hicket and belching; for by these the windinesse contained in the stomacke, is often expelled. By urine, for by this not onely Feavers, but which is more to bee admired, the French-Pockes hath often bene terminated and cured.

For there have bene some troubled with the Pockes, in whom a fluxe of the vicious and venenate humor could not by unctions of quicksilver be procured, either from the mouth, or belly; yet have bene wonderfully freed by abundance of urine, both from danger of death and their disease. By bleeding; for nature hath often found a way for grievous diseases, especially in young bodies, by bleeding at the nose, and by their courses in women. By a fluxe, or laske, purgation, sweats, insensible evacuation and transpiration; for so tumors, the matter being brought to suppuration, doe sometimes vanish away and are dissolved, both of their owne accord, as also by dissolving, or discussing medicins. We doe the same by exercise, diet, hot-houses, long sleepe, waking, and shedding of teares. By sucking, as with cupping glasses and horse-leaches in wounds made by venomous bitings.

We must observe three things in every evacuation.

In all such kinds of evacuations, wee must consider three things, the quantity, quality, and manner of evacuation. As for an example, when an *Empyema* is opened, the matter which runnes out, ought to bee answerable in proportion to the purulent matter, which was contained in the capacity of the breasts; otherwise, unlesse all the matter bee emptied, there may happen a relapse; the matter should be white, soft, equall, and nothing stinking: Lastly, you must let it forth not altogether, and at one time, but by little and little, and at severall times, otherwise not a little quantity of the spirits and heate doth flow out together, with the unprofitable matter, and so consequently a dissolution of all the powers.

CHAP. XVIII.

Of the Perturbations, or Passions of the minde.

He Perturbations, are commonly called the accidents of the minde; because, as bodily accidents from the body, so may these be present and absent from the minde, without the corruption of the subject. The knowledge of these must not be lightly passed over by the Chirurgeon; for they stir up great troubles in the bodies, and yeeld occasion of many & great diseases; of which things, Ioy, Hope and Love, may give a apparent testimony. For by these motions the heate and spirits are sometimes gently, sometimes violently diffused over all the body, for the enjoying of the present, or hoped for good. For then the heart is dilated, as to embrace the thing beloved, and the face is died with a rosy and lively colour. For it is likely, that the facultie it selfe is stirred by the object, by whose power the heart it selfe is moved.

Why the Passions of the minde, are called Accidents. Their force.

For it is first necessary, before wee be moved by any Passions, that the senses in their proper seates, in which they are seldome deceived, apprehend the objects, and strait as messengers carrie them to the common sense, which sends their conceived formes to all the faculties. And then, that each facultie, as a Iudge may a fresh examine the whole matter, how it is, and conceive in the presented objects some shew of good, or ill, to bee desired, or shunned. For what man that was well in his wits, did ever fall into a laughter, unlesse he formerly knew, or saw somewhat said or done, which might yeeld occasion of laughter? Therefore Ioy proceeds from the heart, for the thing causing mirth or joy, being conceived, the facultie moves the heart, which shaken and moved by the faculty which hath dominion over it, is dilated and opened, as ready to embrace the exhilarating object. But in the meane time by the force of that dilatation, it sends forth much heate, and spirits together with the bloud into all the body. A great part of which coming to the face, dilates it, the forehead is smooth and plaine, the eyes looke bright, the cheekes become red, as died with Vermilion, the lips and mouth are drawen together, and made plaine and smoth; some have their cheekes dented with two little pits (which from the effects are called laughing cheekes) because of the contraction or curling, which the muscles suffer by reason of their fulnesse of bloud and spirits, all which to be brieve is nothing but to laugh.

From whence they have their force.

The reason of Ioy.

Ioy recreates and quickens all the faculties, stirres up the spirits, helps concoction, makes the body to bee better likeing, and fattens it, the heate, bloud, and spirits flowing thither, and the nourishing dew or moisture, watering and refreshing all the members; from whence it is, that of all the Passions of the minde, this onely is profitable, so that it exceed not measure; for immoderate and unaccustomed joy, carries so violently the bloud and spirits from the heart, into the habit of the body, that sodaine and unlookt for death ensues, by a speedy decay of the strength, the lasting fountaine of the vitall humour being exhausted. Which thing principally happens to those who are lesse heartie, as women and old men.

The effects of Ioy.

Anger causeth the same effusion of heate in us, but farre speedier than joy; therefore the spirits and humors are so inflamed by it, that it often causes putrid feavers, especially if the body abound with any ill humor.

Anger.

Sorrow, or grieve dries the body by a way quite contrary to that of anger, because by this the heart is so straitened, the heate being almost extinct, that the accustomed generation of spirits cannot be performed; and if any be generated, they cannot freely passe into the members with the bloud; wherefore the vitall facultie is weakened, the lively colour of the face withers and decaies, and the body wastes away with a lingering consumption.

Sorrow.

Feare in like sort drawes in and calls backe the spirits, and not by little and little as in sorrow, but sodainely and violently; hereupon the face growes sodainely pale,

Feare.

the extreame parts cold, all the body trembles or shakes, the belly in some is loosed, the voice as it were staies in the jawes, the heart beate with a violent pulsation, because it is almost opprest by the heate, strangled by the plentie of bloud, and spirits abundantly rushing thither; The haire also stands upright, because the heate and bloud are retired to the inner parts, and the utmost parts are more cold and drie than stone; by reason whereof the utmost skinne and the pores, in which the rootes of the haire are fastened, are drawne together.

Hippocrat. lib.
4. de morb.

Shame.

Shame is a certaine affection mixed, as it were, of Anger and Feare; therefore if, in that conflict of, as it were, contending passions, Feare prevaile over Anger, the face waxeth pale, (the bloud flying backe to the heart,) and these or these Symptomes rise, according to the vehemency of the contracted and abated heat. But if on the contrary, Anger get the dominion over Feare, the bloud runnes violently to the face, the eyes looke red, and sometimes they even come at the mouth.

Shamefast-
nesse.

There is another kinde of shame, which the Latines call *Verecundia* (wee Shamefastnesse) in which there is a certaine fluxe, and refluxe of the heate, and bloud first recoiling to the heart, then presently rebounding from thence againe. But that motion is so gentle, that the heart thereby suffers no oppression, nor defect of spirits; wherefore no accidents worthy to be spoken of, arise from hence: this affect is familiar to young maid es and boyes; who if they blush for a fault committed unawares, or through carelesnesse, it is thought an argument of a vertuous and good disposition.

An agonie.

But an agony, which is a mixt passion of a strong feare, and vehement anger, involves the heart in the danger of both motions; wherefore by this passion, the vitall facultie is brought into very great danger. To these sixe Passions of the minde, all other may be revoked, as Hatred and Discord to Anger: Mirth and Boasting, to Ioy; Terrors, Frights and Swooundings, to Feare; Envy, Despaire and Mourning, to Sorrow.

By these it is evident, how much the passions of the minde can prevaile, to alter and overthrow the state of the body; and that by no other meanes, than that by the compression and dilatation of the heart, they diffuse and contract the spirits bloud, and heate; from whence happens the dissipation, or oppressions of these spirits.

Why the first
signes of pas-
sions of the
minde appeare
in the face.

The signes of these Symptomes quickly shew themselves in the face; the heart, by reason of the thinnesse of the skinne in that part, as it were painting forth the notes of its affections. And certainly the face is a part so fit to disclose all the affections of the inward parts, that by it you may manifestly know an old man from a young, a woman from a man, a temperate person from an untemperate, an Ethiopian from an Indian, a Frenchman from a Spaniard, a sad man from a merry, a sound from a sicke, a living from a dead. Wherefore many affirme that the manners, and those things which we keepe secret and hid in our hearts, may be understood by the face and countenance.

The use of
passions of the
minde.

Now wee have declared what commoditie and discommoditie may redound to man from these forementioned passions, and have shewed that anger is profitable to none, unlesse by chance to some dull by reason of idlenesse, or opprest with some cold, clammy and phlegmaticke humor; and feare convenient for none, unlesse peradventure for such as are brought into manifest and extreme danger of their life by some extraordinary sweat, immoderate bleeding, or the like unbridled evacuation, Wherefore it behoves a wise Chirurgion to have a care, lest he inconsiderately put any Patient committed to his charge into any of these passions, unlesse there bee some necessitie thereof, by reason of any of the forementioned occasions.

CHAP. XIX.

Of things against Nature, and first of the Cause of a Disease.

Having intreated of things naturall, and not naturall, now it remaines wee speake of things (which are called) against nature, because that they are such as are apt to weaken and corrupt the state of our body. And they bee three in number; The cause of a disease, a Disease, and a Symptome. The cause of a disease is an affect against nature, which causes the disease. Which is divided into Internall and Externall. The Externall, originall or primitive comes from some other place, and out wardly into the body, such be meates of ill nourishment, and such weapons and hostilely wound the body.

What things against nature are.

What, and how many the causes of diseases be. The primitive cause.

Internall antecedent.

The Internall have their essence and seate in the body, and are subdivided into antecedent and conjunct. That is called an antecedent cause, which as yet doth not actually make a disease, but goes neare to cause one; so humors copiously flowing, or ready to flow into any part, are the antecedent causes of diseases; The conjunct cause is that which actually causes the disease, and is so immediately joined in affinitie to the disease, that the disease being present, it is present, and being absent, it is absent.

Internall conjunct.

Againe, of all such causes, some are borne together with us, as the over-great quantitie, and maligne qualitie of both the seedes, and the menstruous bloud, from diseased Parents are causes of many diseases, and specially of those which are called Hereditary.

Other happen to us after wee bee borne, by our diet and manner of life, a stroke, fall, or such other like. Those which bee bred with us, cannot be wholly avoided or amended, but some of the other may be avoided, as a stroke and fall; some not, as those which necessarily enter into our body, as Aire, Meate, Drinke, and the like.

But if any will reckon up amongst the internall, inherent, and inevitable causes, the daily, nay hourelly dissipation of the radicall moisture, which the naturall heate continually preyes upon; I doe not gainsay it, no more than that division of causes celebrated and received of Philosophers, divided into Materiall, Formall, Efficient, and Finall; for such a curious contemplation belongs not to a Chirurgion, whom I onely intend plainely to instruct. Wherefore that wee have written may suffice him.

The congenit, or inevitable cause of death.

CHAP. XX.

Of a Disease.

Disease is an affect against nature, principally and by it selfe, hurting and depraving the action of the part in which it resides. The division of a Disease is threefold; Distemperature, ill Conformation, and the Solution of Continuity.

What a disease is, and how various.

Distemperature is a disease of the simular parts dissenting, and changed from their proper and native temper. That digression from the native temper, happens two wayes; either by a simple distemperature from the excesse of one qualitie; and this is fourefold; Hot, Cold, Moist, and Drie; or by a compound distemperature, by the excesse of two qualities, which also is fourefold, Hot and Moist; Hot and Drie, Cold and Moist; Cold and Drie. Againe, every distemper is the fault of one simple and single qualitie, as an inflammation; or hath some vicious humors joyned with it, as a Phlegmon; Againe, a Distemperature is either equall, as in a *Sphacelle*; or unequall, as in a *Phlegmon*, beginning, or increasing.

A Distemperature.

Ill Conformity is a fault of the organick parts, whose composure is

Ill conformation.

Solution of
Continuitie:

is thereby depraved. This hath foure kindes; the first is when the figure of the part is faultie, either by nature or accident, or some cavitie abolished, as if a part, which nature would have hollow for some certaine use, doe grow or close up; or lastly, if they be rough, or smooth otherwise than they should, as if that part which should be rough, be smooth, or the contrary. Another is in the magnitude of the part increased, or diminished contrarie to nature. The third is in the number of the parts, increased, or diminished; as if a hand have but foure or else fixe fingers. The fourth is in the site and mutuall connexion of the parts, as if the parts which should be naturally united and continued bee pluckt asunder, as happens in luxations; or the contrary. The third generall kinde of disease, is the solution of continuitie, a disease common, both to the simular and organicall parts, acquiring diversitie of names, according to the varietie of the parts in which it resides.

CHAP. XXI.

Of a Symptome.

What a Symptome is.

WE doe not in this place take the word Symptome in the most generall acceptation, for every change or accident which happens to man besides his owne nature; but more reservedly and specially, onely for that change which the disease brings, and which followes the disease, as a shadow doth the body.

Three kindes thereof.

There be three kindes of a Symptome properly taken. The first is, when the action is hurt; I say hurt, because it is either abolished, weakened, or depraved; so blindnesse is a deprivation, or abolishing of the action of seeing; dulnesse of sight, is a diminution, or weakening thereof; and a suffusion, such as happens at the beginning of a Cataract, when they thinke flies, haire, and such like bodies flie too and fro before their eyes, is a depravation of the sight.

The second is a simple affect of the body, and a full fault of the habite thereof being changed, happening by the mutation of some qualities, such is the changing of the native colour into a red by a Phlegmon, and into a livide and blacke by a Gangrene; such is the filthy stench the nose affected with a *Polypus* sends forth; the bitter taste, in such as have the laundise; and the rough and rugged skinne in them which are Leprous.

The third is the fault of the overmuch retention of excrements which should be expelled, and expulsion of such as should be retained; for the evacuation of an humor profitable both in quantitie and qualitie, is against nature, as bleeding in a body not full of ill humors, nor Plethoricke; and also the retention of things hurtfull in substance, quantitie and qualitie, as the Courses in women, the urine, and the stone in the bladder.

CHAP. XXII.

Of Indications.

What an Indication is.

His knowledge and exercise of Indications befits that Chirurgion, whom no blinde rashnesse of fortune, but reason; no chance, but counsell directs in the undertaking and performing the workes of his Art. For an Indication is a certaine safe and short way, which leades the Physition, as by the hand, to the attainment of his purposed end, of preserving the sound, or curing the sicke.

Sec. method.
Cap. 7. lib. de
op. secta,
Cap. 11.

For *Galen* doth define an Indication to be a certaine insinuation of what is to be done, or a quick & judicious apprehension of that which may profit or hurt. And as *Faulconers*,

ners, Mariners, Plowmen, Soldiers, & all manner of Artizans, have their peculiar termes and words, which are neither knowne, nor used by the vulgar; so this word Indication is proper and peculiar to Physicians and Chirurgeons, as a Terme of Arte not vulgar; by consideration of which, as by some signe, or secret token, they are admonished what is to be done to restore health, or repell an imminent danger.

There are three prime and principall kinds of Indications, every of which is subdivided into many other. The first is from things naturall. The second from these things which are termed not naturall. The third from those things which are contrary to nature. Things naturall shew they must be preserved by their like, and in the compasse of these are contained all the Indications which are drawne from the nature of the Patient, that is, from his strength, temper, age, sexe, habit, custome, diet.

The kinds of
Indications.

Things not naturall may be doubted as uncertaine, for one while they indicate the same things with things naturall, that is, they coindicate with the strength, temper and the rest; other whiles they consent with things against nature, that is, they coindicate with the disease. Wherefore *Galen* when he saith, that Indications are drawn from three things; The disease; The nature of the Patient, and the encompassing aire, by proposing the familiar example of the aire, hee would have us to understand the other things not naturall; because wee may shun, or embrace them more or lesse as we will our selves, but we must, whether we will or no, endure the present state of the aire. Therefore the aire indicates something to us, or rather coindicates; for if it nourish the disease, as conspiring with it, it will indicate the same that the disease, that is, that it must be preserved in the same state.

Lib. 9. Method.
cap. 9.

Things contrary to nature indicate they must be taken away by their contraries; therefore that we may more accurately and fully handle all the Indications drawne from things naturall, we must note, that some of these are concerning the strength of the Patient, by care to preserve which, we are often compelled for a time to forsake the cure of the proper disease: for so a great shaking happening at the beginning of an ague or feaver, we are often forced to give sustenance to the Patient, to strengthen the powers shaken by the vehemency of the shaking, which thing notwithstanding lengthens both the generall and particular fits of the ague. Other pertaine to the temper, other respect the habite, if the Patient be slender, if fat, if well flesht, if of a rare, or dense constitution of body. Other respect the condition of the part affected in substance, consistence, softnesse, hardnesse, quicke or dull sense, forme, figure, magnitude, site, connexion, principallity, service, function and use. From all these, as from notes the skilfull Chirurgeon will draw Indications according to the time and part affected: for the same things are not fit for fore eyes, which were convenient for the eares, neither doth a Phlegmon in the jawes and throat admit the same forme of cure, as it doth in other parts of the body. For none can there outwardly apply repercussives, without present danger of suffocation. So there is no use of repercussives in defluxions of those parts which in site are neere the principall. Neither must thou cure a wounded Nerve and Muscle, after one manner. The temperature of a part, as Moisture, alwayes indicates its preservation, although the disease be moist and give Indication of drying, as an ulcer. The principallity of a part alwayes insinuates an Indication of astringent things, although the disease require dissolving, as an Obstruction of the Liver; for otherwise unlesse you mixe astringent things with dissolving, you will so dissolve the strength of the part, that hereafter it cannot suffice for sanguification. If the texture of a part be rare, it shewes it is lesse apt, or prone to obstruction; if dense, it is more abnoxious to that disease; hence it is that the Liver is oftener obstructed than the Spleene. If the part be scituate more deepe, or remote, it indicates the medicines must be more vigorous and liquid, that they may send their force so farre. The sensiblenesse, or quicke-sense of the part, gives Indication of milder medicines, than peradventur the signes, or notes of a great disease require. For the Physician which applies things equally sharpe to the Horny tunicle of the eye being ulcerated, and to the Legge, must needs be accounted either cruell, or ignorant. Each sexe and Age hath its Indications, for some diseases are curable in youth, which we must not hope to cure in old age; for hoarsenesse and great distillations in very old men, admit no digestion, as *Hippocrates* saith;

Indications
drawne from
things naturall.

What the con-
ditions of the
parts affected
do indicate.

Indications
from the ages.

Apher. 40. li. 2.

Nunquam

Nunquam decrepitus Branchum coquit, atque Coryzam.

The feeble Sire, for age that hardly goes,
Ne're well digests, the hurtfull Rheume or pose.

Moreover according to his decree the diseases of the Reines, and whatsoever paines molest the bladder, are difficultly healed in old men; and also reason persuades that a Quartaine admits no cure in Winter, and scarce a Quotidian, and ulcers in like manner are more hard to heale in Winter; that hence we may understand certaine Indications to be drawne from time; and to increase the credit of the variety and certainty of Indications, some certaine time, and seasons in those times command us to make choise of Medicines; for as *Hipocrates* testifies;

Ad Canis ardorem facilis purgatio non est.

In Dogdayes heat it is not good,
By purging for to cleanse the blood.

Neither shalt thou so well prescribe a slender diet in Winter, as in the Spring, for the aire hath its Indications. For experience teaches us, that wounds of the head are farre more difficultly and hardly cured, at Rome, Naples, and Rochell in Xantaigne. But the times of diseases yeeld the principall Indications, for some Medicines are onely to be used at the beginning and end of diseases, others at the encrease and vigour of the disease. We must not contemne those Indications which are drawn from the vocation of life, and manner of Diet; for you must otherwise deale with the painfull Husbandman (when he is your Patient) which leades his life sparingly and hardly, than with the Citizen who lives daintily and idly. To this manner of life and Diet may be referred a certaine secret and occult property, by which many are not onely ready to vomite at eating of some meats, but tremble over all their bodies when they heare them but spoken of. I knew a prime Nobleman of the French Nobility, who was so perplexed at the serving in of an Eele to the Table, at the middst of dinner & amongst his friends, that he fell into a swoond, all his powers failing him. *Galen* in his booke *de Consuetudine* tells that *Arius* the *Peripateticke* died suddenly, because compelled by the advise of those Physicians he used, he dranke a great draught of cold water in the intollerable heat of a Feaver. For no other reason saith *Galen*, than that, because he knowing he had naturally a cold stomacke from his childhood, perpetually abstained from cold water.

For as much as belongs to Indications taken from things against nature; the Length and depth of a wound or ulcer indicates one way; the figure cornered, round, equall and smooth, unequall and rough, with a hollownesse straight or winding, indicate otherwise; the site right, left, upper, lower in another manner, and otherwise the force and violence of antecedent and conjunct causes. For oftentimes the condition of the cause indicates contrary to the disease, as when abundance of cold and grosse humors cause and nourish a Feaver. So also a Symptome often indicates contrary to the disease, in which contradiction, that Indication must be most esteemed, which doth most urge; as for example sake, if swoounding happen in a Feaver, the feaverish burning shall not hinder us from giving wine to the Patient.

Wherefore these Indications are the Principallest and most noble which leade us, as by the hand, to doe these things which pertaine to the cure, prevention and mitigating of diseases. But if any object, that so curious a search of so many Indications is to no purpose, because there are many Chirurgions, which setting onely one before their eyes, which is drawne from the Essence of the disease, have the report and fame of skillfull Chirurgions, in the opinion of the vulgar; but let him know that it doth not therefore follow, that, this indication is sufficient for the cure of all diseases; for we doe not alwayes follow that which the Essence of the disease doth indicate to be done. But chiefly then, where none of the fore-recited Indications doth resist or gainsay; you may understand this by the example of a *Plethora*, which by the Indication drawne from the Essence of the thing requires Phlebotomy; yet who

is

wayes follow
the Indication
which is from
the disease.

is it, that will draw blood from a child of three monethes old? Besides, such an Indication is not artificiall but common to the Chirurgion with the common people. For who is it that is ignorant, that contraries are the remedies of contraries? and that broken bones must be united by joyning them together? but how it must be performed and done, this is of Arte and peculiar to a Chirurgion, and not knowne to the vulgar. Which the Indications drawn from those fountaines we pointed at before, abundantly teaches, which, as by certaine limits of circumstances, encompass the Indication which is taken from the Essence of the disease, lest any should thinke, we must trust to that onely. For there is some great and principall matter in it, but not all. For so the meanest of the common people is not ignorant, that the solution of continuity is to be cured by repairing that which is lost. But in what parts we may hope for restitution of the lost substance, and in which not, is the part of a skilfull Chirurgion to know and pronounce. Wherefore hee will not vainly bestow his labour to cure the Nervous part of the *Diaphragma*, or Midriff being wounded, or the Heart, small Gutts, Lungs, Liver, Stomacke, braine or bladder; and that, I may speake in a word, Emperickes are not much more skilfull than the common people, although they do so much extoll themselves above others by the name of experience. For although experience be another instrument to find out things with reason, yet without reason, it will never teach, what the substance of the part in which the disease lyes, may be; or what the action, use, site, connexion, from whence speciall and proper Indications are drawne; With which the Chirurgion being provided and instructed shall not onely know by what meanes to finde out a remedye, but also, lest he may seeme to mocke any with vaine promises, he shall discerne what diseases are uncureable, and therefore not to be medled withall.

In what parts we cannot hope for restoring of solution of continuity.

Experience without reason is like a blind man without a guide.

But implicate, or intricate diseases require each to be cured in their severall order, except some one of them be desperate, or so urge and presse that the Physition think it necessary after a preposterous order, to begin with it, although often he be forced to make some one of these diseases incurable, or give occasion of causing some new one, into which straits we are necessarily compelled to fall, when, (for example) we determine to pull, or take away some extraneous body; for the performance whereof we are compelled to enlarge the wound. So we are forced by necessitie to open the necke of the bladder, (that so we may draw forth the stone therein contained) with a wound which often degenerates into an incurable Fistula. For that disease which threatens danger of present death is of such moment, that to shun that, it may be counted a smal matter, and commodious for the sicke to bring in other diseases, though uncureable. For if a convulsion happen by pricking a Nerve which we cannot heale by any remedies, then by cutting the Nerve asunder wee end the convulsion, but deprive the part into which that Nerve did goe, of the use of some voluntary motion. So if in any great joynt there happen a Luxation with a wound, because there is danger of convulsion by trying to restore and set right the Luxated part, wee are forced for shunning thereof, to attend the wound onely, and in the meane time to let alone the Luxation. Otherwise in implicate diseases if there be nothing which may urge, or call us from the ordinary cure, we must observe this order, that beginning with that affect, which hinders the cure of the principall disease, we prosecute the rest in the same and their proper order, untill all the diseases being overcome we shall restore the part affected to its integrity. Therefore let us take for an example, an ulcer in the Leg, a *Varix* (or big swollen veine) and a Phlegmonous tumor round about it; and lastly, a body wholly plethoricke and filled with ill humors; order and reason require this, that using the advise of some learned Physition we prescribe a convenient diet, and by what meanes we may, bring him to an equality by purging and blood-letting, and then we will scarifie in divers places the part where it is most swollen, then presently apply Leaches that so we may free it from the burden of the conjunct matter; then use Cauteryes to helpe the corruption of the bone, and in the meane time change the circular figure of the ulcer into an ovall, or triangular; then at the length we will undertake the cutting of the *Varix*, and cure the ulcer which remains according to Arte, and so at the length cicatrize it. In all this whole time the Patient shall neither walke, nor stand, nor sit, but lye quietly, having his Leg orderly and decently rowled up. But

if (as it often happens) the temper of the hurt part, be different from the temper of the whole body, the manner of curing must be so tempered, that we increase the Dosis of hot or Cold medicines, according to the ratable proportion of the Indications requiring this, or that. Therefore imagine the part ulcerated to be such, as that it is two degrees dryer than the just temper; but the whole body to exceed the same temper in one degree of humidity: reason and Arte will require, that the medicine applyed to the ulcer be dryer by one degree than that which the part would otherwise require if it were temperate; but on the contrary let us suppose thus. The whole body to be one degree more moist than the temper requires, & the ulcerated part to be one degree dryer, truly in this case the medicine that is applyed to the ulcer by reason of the part it selfe, shall not be encreased in drynesse, but wholly composed and tempered to the Indication of the ulcer, because the force of the moisture exceeding in the like degree, doth counterpoise the superfluous degree of drynesse. But it is more easie by an artificiall conjecture to determine of all such things, than by any rules or precepts.

To these so many and various Indications, I thinke good to add two other; the One from similitude; the Other of a certaine crafty device, and as the latter Physitions terme it, of a certaine subtile stratageme. We draw Indication from similitude, in diseases which newly spring up and arise, as which cannot be cured by Indications drawne from their contraries, as long as their Essence is unknowne and hid; wherefore they thinke it necessary to cure them by a way and Arte like those diseases, with which they seeme to have an agreeing similitude of Symptomes and Accidents; Our Ancestors did the same in curing the French Pockes, at the first beginning thereof, as long as they assimilated the cure to that of the Leprosie, by reason of that affinity, which both the diseases seeme to have. But we follow crafty devices and subtile counsells, when the Essence of the disease wee meet with is wholly secret and hid, either because it is altogether of a hidden and secret nature, and which cannot be unfolded by manifest qualities, or else resides in a subject which is not sufficiently knowne to us, nor of a Physicall contemplation, as the Minde. For then we being destitute of Indications taken from the nature of the thing, are compelled to turne our cogitations to impostures and crafty counsells; and they say this Arte and Craft is of cheife use in Melancholy affects and fictions, which are often more monstrous and deformed than the Chimera so much mentioned in the fables of the Ancients; to which purpose, I will not thinke much to recite two Examples. A certaine man troubled with a Melancholike disease, I know not by what error of opinion, had strongly perswaded himself that he was without a head; the Physitions omitted nothing, by which they might hope to take this madd opinion out of his minde. But when they had in vaine tryed all medicines, at length they devised this crafty, but profitable device, they fastened and put upon his head a most heavy helmet, that so by the paine and trouble of his head nodding and drawne downe by that weight, he might be admonished of his error.

It is reported, another molested by the obscurity and darknesse of the same disease, did verily beleieve, that he had hornes upon his head; neither could he be drawne or diverted from that absurd and monstrous opinion, untill that binding up his eyes, they miserably bruised and seratched his forehead with the bony roughnesse of the lower parts of an oxes hornes, that so he begun to beleieve by the painefull drawing of the blood that ran downe his face, that those bloody hornes, were forcibly plucked from him. Ingenious Chirurgions in imitation of these examples may in like cases doe the like. For that case requires a man of a quicke apprehension and advice, who may give manifest proove of his diligence and skill by medicinall stratagems, as who forthwith can politickly device stratagems of divers sorts.

But, now comming to the end of this our tract of Indications, we must cheifly and principally observe; That of Indications some are Indicative; which absolutely and of themselves command this to be done; other coindicative, which indicate the same with the Indicative, and joyntly shew it to be done, but in some sort secundarily and not primitively; some are repaguant, which of themselves and their owne nature perswade quite contrary to that the indicative primitively did; or which disswade us from doing that, to performe which the indicative did perswade us; other correpugnant,

correpugnant, which give their voyce after the same forme and manner with the repugnant against the indicative, as the coindicative consent to and maintaine them. Let this serve for an example of them all.

A *Plethora*, or plenitude of humors of its owne nature, requires and indicates blood-letting, the Spring-time perswades and coindicatives the same, but to this counsell is quite opposite and repugnant, a weake faculty, and childhood is correpugnant.

Wherefore these foure must be diligently waighed and considered when we deliberate what is to be done, and we must rather follow that which the indicative, or repugnant shew and declare, as what the disease and strength of the Patient require, than that which the coindicative, or correpugnant shall perswade, because they have a weaker and but secundary power of indicating, and not essentiall and primitive. But because the kinds of Indications are so many and divers, therefore that the knowledge of them may be more perspicuous and lesse confused, I have thought good to describe & distinguish them by this following scheme.

A

A Table of Indications.

An Indication is a certaine plaine and compendious way which leades the Chirurgion to a certaine, determinate and proposed end for the cure of the present diseases of which there are 3. kinds,

The first is drawne from things natural which indicate their preservation by their like; of this kind are many other which are drawne,

either

- From the strength and faculties of the patient. For whose preservation, oftentimes the proper cure of the disease must be neglected; for where these faile, it is impossible the Chirurgion should performe what he desires and expects.
- From the temperment, as if the Patient shall be—Sanguine, Cholericke, Flemmaticke, Melancholicke. Of preservation of which the Chirurgion must have care, and if they swarve from equallitie, to reduce them to that which formerly they naturally were.
- From the habite of the body, as the patient shall be—Dainty and delicate, Slender and weak, Low of stature, Rare, or else dense and compacte.
- From the native condition of the hurt or affected part, in which we consider, either—The substance thereof, as for as much as it is simular we consider whether it be hot, cold, moist, dry, or as it is organickall, and then whether it be a principall and noble part, or a subordinate and ignoble part. Or, the sense whether quicke, or dull, by reason whereof the eye cannot endure such sharpe & acride medicines, as simple flesh can. Or the forme, figure, magnitude, number, site, connexion, action, use.
- From the Age, for each age yeelds his peculiar Indications, hence you may observe most diseases to be incureable in old men, which are easily cured in yong, others which in youth admit of no cure, unless by the change of age and th' ensuing temperament.
- From Sexe, for medicines work upon weomen farre more easily than upon men.
- From the time of the yeare, for some meats and medicines are fit in Winter, some in Summer.
- From the Region, for as there are diversities of situations and habits of places, so also there are motions of humors, and manners of diseases: hence it is that wounds on the head at Paris, & sore shins at Avignon are more difficult to be cured.
- From the times of diseases, for some things in the beginnings, others in the encrease, state and declining of the disease, are more convenient.
- From the manner of diet, for this, as the proper temper, must be preserved. Wherefore such must be fed otherwise who live daintily, than those who leade their lives sparingly and hardly. Hereunto adde certaine peculiar natures, which by a certaine hidden property are offended at this, or that kinde of meate. For there are some which not onely, cannot concoct Ptisane, Apples, Soles, Pertridge, Water and such like, but can scarce behold them without Nauseousnes.

The second is drawne from things not naturall, which one while indicate their preservation by their like, another while their change by their contraries; for so

If the Aire, have as it were conspired with the disease by a certaine similitude of qualities to the destruction of the Patient, it must be corrected by its contraries according to Arte. But if by the disagreement of qualities it resist the disease, it must be kept in the same temper.

The third from things contrary to nature which shew they must be taken away by the use of their contraries, as

The disease, the Indication being drawne from these

The greatest The complication or commixtion with others so

In implicate, or mixed diseases we may draw Indications from these 3. heads,

From that which is most urgent

From the cause

and From that, without which the disease can not be taken away

such are

Bitternesse of paine, a defluxion into a part, a Varix, or bigge swollen veine, a distemperature if they be joyned with a disease.

Cause of the disease

Symptomes

which two oft indicate & require medicines contrary to the disease.

CHAP. XXIII.

Of certaine wonderfull and extravagant wayes of Curing diseases.

 S Monsters sometimes happen in nature, so also in diseases, and in the events and cures of diseases. I understand by monsters certaine marvellous successes in diseases, or certaine wayes of curing them, which swarve from Arte, and happen besides reason, nature, and common use.

Monstrous diseases,

Alexander ab Alexandro, and *Peter Gilius* tell, that in *Apulia* a part of *Italy*, they have a certaine kind of Spider very frequent, the natives call it *Tarentula*, *Petrus Rhodius* calls it *Phalangium*; The Inhabitants finde these Spiders in the first heate of Summer so venenate and deadly, that whomsoever they touch with their virulent biting, he presently, without he have speedy remedy, deprived of all sense and motion falls downe, or certainly if he escape the danger of death, he leades the remnant of his life in madnesse. Experience hath found a remedy by Musicke for this so speedy and deadly a disease; Wherefore as soone as they can they fetch Fiddlers and Pipers of divers kinds, who by playing and piping may make Musicke, at the hearing whereof, he which was fallen downe by reason of the venomous bite, rises cheerfully and dances so long to their measures and tunes, untill by the painfull & continued shaking and agitation of the whole body, all the malignity is dissipated by transpiration and sweates.

The wonders full force of the bite of a certaine Spider,

Musicke the remedy therof.

Alexander adds that it happened once in his sight, that the Musitions their winde & hands failing them ceased playing, and then the Danser presently fell downe as if hee had beene dead; But by and by the Musicke beginning anew, he rise up againe and continued his dancing till the perfect dissipation of the venome. And that it hath happened besides, that one not so perfectly healed, certaine reliques of the disease yet remaining, when a long time after he heard by chance a noise of Musitions, he presently fell a leaping and dancing, neither could he be made to leave before he was perfectly cured.

Some affirme according to the opinion of *Asclepiades*, that such as are Franticke are much helped with a sweet and Musicall harmony. *Theophrastus* and *Aulus Gellius* say that the paine of the Goute and Sciatica are taken away by Musicke. And the Sacred Scripture testifies, that *David* was wont by the sweet sound of the Harpe to refresh and ease King *Saul* when he was miserably tormented by his evill spirit. *Herodotus* in *Clio* tells, that *Craesus* the King of *Lydia* had a Sonne, which of a long time could not speake, and when hee came to mans estate was accounted dumbe: but when an Enemy with his drawne sword invaded his father (overcome in a great fight, and the City being take in which hee was) not knowing that hee was the King, the young man opened his mouth endeavoring to cry out, and with that striving and forcing of the Spirit hee broke the bonds and hinderances of his tongue, and spoke plainly and Articulately, crying out to the Enemy that hee should not kill King *Craesus*. So both the Enemy withheld his sword, and the King had his life, and his Sonne had his speech alwayes after. *Plutarch* in his booke, Of the benefit to be received from our Enemies, tells that a Theſſalian called *Proteus*, had a certaine inveterate and incurable ulcer in a certaine part of his body, which could not be healed, before hee received a wound in a conflict in the same place, and by that meanes the cure being begun afresh, the wound and ulcer were both healed.

Musicke gives ease to paine.

A strong perturbation of the minde helps by moving the spirits.

Quintus Fabius Maximus, as *Livy* writes, was long and very sicke of a quartaine Ague, neither could have wished successe from medicines administred according to Arte, untill skirmishing with the *Allobroges* hee shook off his old feaverish heate, by a new heate and ardent desire of fighting. It was credibly reported to me of late by a Gentleman of the Lord of *Lansackes* Chamber, that there was a French Gentleman in *Polonia* who was greivously tormented with a quartaine

Chance sometimes exceeds Arte.

Feaver, who on a time walking upon the banke of the River Wixell to take away the irkesomenesse of his fit, was thrust in jeast into the River by a friend of his that met him by chance, by which (although hee could swim, as hee also knew that thrust him in) hee conceived so great feare, that the Quartaine never troubled him after. King Henry the second commanded me to goe from the Campe at Amiens to the City Dorlan, that I might cure those that were hurt in the conflict with the Spaniards, the Captaine S. Arbin although at that time he had a fit of a quartaine ague, yet would hee be present at the fight, in which being shot through the side of his necke with a Bulle, hee was stricken with such a terror of death, that the heate of the Feaver was asswaged by the cold feare, and he afterwards lived freed from his Ague.

Observat. 4.
lib. 2.

Franciscus Valleriola the famous Physition of Arles, tells that John Berlam his fellow Citizen troubled with a Palsey of one side of his body for many yeares, his house taking fire, and the flame comming neere the bed in which he lay, he stricken with a great feare, suddenly raised himselfe with all the force hee had, and presently recovering the strength of his body, leapes out at the window from the top of the house, and was presently cured of his disease, sense and motion being restored to the part, so that afterward hee went upright without any sense of paine, who lay unmoveable for many yeares before. Hee tells the like in the same place of his cosen John Sobiratus; hee was a long time lame at Auignion, by reason that the nerves of his hams were shrunk and drawne up so that hee could not goe; being moved with a vehement and suddaine passion of anger against one of his servants whom hee endeavored to beate, hee so stirred his body that forthwith the Nerves of his hams being distended, and his knees made plyant hee began to goe and stand upright without any sense of paine, when hee had beene crooked about the space of six yeares before, and all his life after he remained sound.

Galen by a
dreame cures
the Sciatica.

Galen tells hee was once fetched to stanch the bleeding, for one who had an Artery cut nere his ancle, and that by his meanes hee was cured without any danger of an *Aneurisma* (i) a relaxation of a veinous vessell, and besides by that accidentall wound hee was freed from most greivous paine of his hippe, with which he was tormented for foure yeares before; but although this easing of the paine of the Sciatica happened according to reason by the evacuation of the conjunct matter, by the artery of the ancle of the same side being opened; yet because it was not cut for this purpose, but happened onely by chance, I judged it was not much dissenting from this argument.

Pliny writes that there was one named Phalereus, which casting up blood at his mouth, and at the length medicines nothing availing, being weary of his life, went unarmed in the front of the battell against the enemy, and there receiving a wound in his breast, shed a great quantity of blood, which gave an end to his spitting of blood, the wound being healed, and the veine which could not containe the blood being condensate.

At Paris Anno 1572. in July a certaine Gentleman being of a modest and courteous cariage fell into a continuall Feaver, and by that meanes became Franticke, moved with the violence of which hee cast himselfe headlong out of a window two storyes high, and fell first upon the shoulder of Vatterra the Duke of Alenzons Physition, and then upon the pavement; with which fall hee cruelly bruized his ribbs and hippe, but was restored to his former judgment and reason. There were present with the Patient besides Vatterra, witnesses of this accident these Physitions, Alexis, Magnus, Duretus, and Martinus. The same hapened in the like disease, and by the like chance to a certaine Gascoyne lying at the house of Agrippa in the Paved streete.

Othomannus Doctor of Physicke of Mompelier and the Kings professor, told me that a certaine Carpenter at Broquer a village in Switzerland, being franticke cast himselfe headlong out of an high window into a river, and being taken out of the water was presently restored to his understanding.

But if we may convert casualties into counsell and Arte, I would not cast the Patient

Patient headlong out of a window. But would rather cast them sodainely and thinking of no such thing into a great cesterne filled with cold water, with their heads foremost, neither would I take them out untill they had drunke a good quantitie of water, that by that sodaine fall and strong feare, the matter causing the Frenzy might be carryed from above downewards, from the noble parts to the igno- noble; the possibility of which is manifest by the forerelated examples, as also by the example of such as bit by a mad Dogge, fearing the water are often ducked into it to cure them.

The cause of the last recited cures.

CHAP. XXIIII.

Of Certaine juggling and deceiptfull wayes of Curing.

Here I determine to treat of those Impostors, who taking upon them the person of a Chirurgeon, doe by any meanes either right or wrong put themselves upon the workes of the Arte; but they principally boast themselves amongst the ignorant common sort, of setting bones which are out of joynt and broken, affirming as falsly as impudently that they have the knowledge of those things from their Ancestors; as by a certaine hereditary right; which is a most ridiculous fiction; for our mindes when we are borne, is as a smoth table, upon which nothing is painted. Otherwise what need wee take such labour and paines to acquire and exercise sciences? God hath endued all brute beasts with an inbred knowledge of certaine things necessary for to preserve their life, more than man.

Sciences are not hereditary

But on the contrary hee hath enriched him with a wit furnished with incredible celerity and judgment, by whose diligent and laborious agitation he subjects all things to his knowledge. For it is no more likely, that any man should have skill in Chirurgery because his father was a Chirurgeon, than that one who never endured sweat, dust nor Sunne in the field, should know how to ride and governe a great horse, and know how to carry away the credite in tilting, onely because hee was begot by a Gentleman and one famous in the Arte of Warre.

There is another sort of Impostors farre more pernicious and lesse sufferable, boldly and insolently promising to restore to their proper unity and seate, bones which are broken and out of joynt, by the onely murmuring of some conceited charmes, so that they may but have the Patients name and his girdle. In which thing I cannot sufficiently admire the idlenesse of our Country-men so easily crediting so great and pernicious an error; not observing the inviolable law of the ancient Physitions, and principally of Divine Hippocrates, by which it is determined, that three things are necessary to the setting of bones dislocated and out of joynt; to draw the bones asunder; to hold the bone receiving, firmly immoveable with a strong and stedy hand; to put the bone to be received into the cavity of the receiving. For which purpose the diligence of the Ancients hath invented so many engines, Glossocomies and bands, lest that the hand should not be sufficient for that laborious worke; What therefore is the madnesse of such Impostures to undertake to doe that by words, which can scarce be done by the strong hands of so many Servants, and by many artificial engines?

A most impudent sort of Impostors.

Three things necessary for the cure of a Luxation,

Of late yeares another kind of Imposture hath sprung up in Germany, they beate into fine powder a stone within there mother tongue they call *Bembruch*, and give it in drinke, to any who have a bone broken, or dislocated, and affirme that it is sufficient to cure them. Through the same Germanie there wander other Impostors who bid to bring to them the Weapons with which any is hurt; they lay it up in a secret place and free from noise, and put and apply medicines to it, as if they had the patient in distress, and in the meane time they suffer him to go about his busines, & impudently

affirme

affirme that the wound heales by litle and litle by reason of the medicine applyed to the weapon,

But it is not likely that a thing inanimate which is destitute of all manner of sence, should feele the effect of any medicine; and lesse probable by much, that the wounded party should receive any benefit from thence. Neither if any should let mee see the truth of such juggling by the events themselves and my owne eyes, would I therefore beleieve that it were done naturally and by reason, but rather by charmes and Magicke.

In the last assault of the Castle of *Hisdin* the Lord of *Martignes* the elder was shot through the breast with a Musket bullet. I had him in cure together with the Physitions, and Chirurgions of the Emperoure *Charles* the first and *Emanuel Philibert* the Duke of Savoy, who because hee entirely loved the wounded prisoner, caused an assembly of Physitions and Chirurgions to consult of the best meanes for his cure. They all were of one opinion, that the wound was deadly and incurable, because it passed through the midst of his lungs, and besides had cast forth a great quantity of knotted blood into the hollownesse of his brest.

There was found at that time a certaine Spaniard, a notable Knave, and one of those Impostors who would pawne his life, that hee would make him sound; wherefore this Honorable Personage being in this desperate case was committed to his care. First of all hee bid they should give him the Patients shirte, which hee tore into shreds and peeces, which presently framing into a Crosse, hee laid upon the wounds whispering some conceived or coined words, with a low murmure. For all other things hee wished the Patient to rest content, and to use what diet hee pleased, for hee would doe that for him, which truly, he did. For hee eate nothing but a few Prunes, and drunke nothing but small beere, yet for all this the wounded Prince died within two dayes; the Spaniard slipt away, and so scaped hanging. And whilst I opened the body in the sight of the Physitions and Chirurgions to embalme him, the signes and accidents of the wound did evidently and plainly appeare to be as we had pronounced before.

What wounds
may be cured
onely by lint,
or by tents and
water.

And there be also other Iugling companions of this tribe, who promise to cure all wounds with linte, or Tents either dry, or macerated in oyle, or water, and bound to the wound, having murmured over some charme or other, who have had sometimes, good successe, as I can witnesse. But the wounds upon which triall was made were simple ones, which onely required union, or closing for to perfect the cure. So verily the bones of beasts when they be broke, grow together by the onely benefit of Nature. But when the affect shall be compound by diversity of Symptomes, as a wound with an ulcer, inflammation, contusion and fracture of a bone, you must hope for no other from Tents or Lints, nor charmes than death. Therefore the common sort who commit themselves to these Impostors to be cured, doe not onely injure themselves, but also hurt the Common-wealth, and the common profit of the Citizens; for whose good and justice sake a prudent Magistrate ought to deprive impostors of all freedome in a free and Christian common-weale.

Witches, Conjurers, Diviners, Soothsayers, Magitians and such like, boast of curing many diseases; but if they doe or performe any thing in this kind, they doe it all by slights, subtilties and forbidden Arts, as Charmes, conjurations, Wircherics, Characters, Knots, Magicall Ligatures, Rings, Images, Poysons, laces tyed a-crosse, and other damnable trickes, with which they pollute, pervert and defame the prime and sacred Arte of Physick & that with the danger of mens lives. Who certainly are to be banished by the lawes of our country, especially seeing it is decreed in

Deuteron. 18. *Moses Law.* Let none be found among you that useth witchcraft, or a regarder of times, or a marker of the flying of Fowles, or a Sorcerer or a Charmer, or that counselleth with Spirits, or a Soothsayer, or that asketh counsell at the dead; for all that doe such things, are abomination to the Lord, and because of these abominations the Lord thy God doth cast them out before thee. But the Miracles of our

our Lord Iesus Christ the Sonne of God, and of his Saints and Apostles in curing diseases beyond nature and all Arte, are of another kind, which we ought to beleieve to firmly and constantly, that it should be counted an impiety for a Christian to doubt of them. All holy writings are full of these, as to give sight to the blinde, hearing to the deafe, power to goe to those sicke of the Palsey, to drive forth Devils, to cure the Leprosy, to give fruitfullnesse to weomen, to raise the Dead, and performe by the holy Ghost other Miracles which exceed the condition and law of Nature: whom here we earnestly intreat to free and protect us from uncleane Divels and the spirits of diabolicall deceit, and to give us the minde that we may will and be able alwayes to aspire to Heaven and fasten the hope, safety and anchor of all our fortunes in God alone. Amen.

*The End of the first
Booke.*

F 3

T H E

THE SECOND BOOKE OF LIVING CREATVRES, AND OF THE EXCELLENCY Of Man.

Efore I come to speake of the Anatomic of mans body; I have thought fit to say a little of the nature of brute Beasts. The difference of brute beasts. There is betweene beastes a great deale of difference by nature; for of these, some are hardy and bold, others fearefull; some wilde and savage, others tame; some walking in heards, others wandring alone; some covered and defended with shels and scales, as the Crocodile, the Tortois and many kinds of fish, others have stings and prickles.

The Horse hath his hard and strong hooves, his crest (as being a generous beast) beset with a thicke and harsh mane, The defence of the magnanimous Lion, are his teeth, his crooked pawes and taile; Bulls are formidable by their hornes; the Boare by his tuskes standing out, as it were naturall hunting speares. The Hare being a timorous creature, is naked and unarmed, but in recompence thereof nature hath made her nimble and swift of foot. For what the more noble and couragious beasts have in armes, is supplied in the fearefull by nimbleness and celerity. Infinite are the other endowments of brute beasts, and such as can hardly be imagined, or described. For if wee diligently search into their nature, wee shall observe the impressions and shadowes of many vertues, as of magnanimitie, prudence, fortitude, clemency, and docillitie: for they entirely love one another, follow those things that are good, shunne those that are hurtfull, and gather and lay up in store those things that are necessary for life and food. Lastly, they give undoubted presages of the weather, and Aire. They have taught men many things, and are of a most exquisite and quicke sense; of rare Art in vocall musicke, prudent and carefull for their young, and faithfull lovers of their native soile. They are religiously observant of the rights of friendship and chastitie. They have their weapons whereby they are prepared, both to invade, and to defend themselves being invaded; they submit themselves to the discipline of man, practise and imitate his speech, and mutually prattle and chant one to another. They have a kind of weale-publique amongst themselves, and know

Some shadow
of vertue in
beasts.

know how to preserve their present welfare, and to depell the contrary, being in this their owne Counsellors, and not tutored by man. Yea man is beholden to them for the knowledge of many wholesome things. The consideration of which bred so great a doubt amongst the ancient Philosophers, that it was a question amongst them, whether beasts had use of reason, or no? Therefore also the wise *Salomon* sends us for examples of parsimonie and diligence unto the Ant or Pismire; and *Esaïas* in exprobration of the people of Israel for their ingratitude and rebellion against God, sends them to the Oxe and Ass; for they doe not onely know, but reverence their Maisters.

Lib. 8. cap. 27.

The crafti-
nesse of Beares,

The bird Ibis
the first inven-
ter, or shewer
of Clusters.

The invention
of removing
a Cataract.

The invention
of Phleboto-
mie,

A preservative
against thun-
der,

But from whence is the knowledge of these medicines, wherewith the Art of Physicke is so richly adorned, but from brute beasts, as *Pliny* affirmeth. The infallible vertue of the herbe *Dictamnus*, in drawing darts out of the flesh, was taught us by the Hart, who wounded with the Huntsmans darts or arrowes, by meanes hereof drawes out the weapons which remaines sticking in her. Which is likewise practised by the Goates of Candie, as *Aristotle* writeth. The wonderfull effect which *Celandine* hath upon the sight, was learnt by the practise of Swallowes, who have bin observed with it to have beineared, and so strengthened the eyes of their young. Serpents rubbe their eyelids with fennell, and are thought by that meanes to quicken and restore the decaying sight of their eyes. The Tortois doth defend & strengthen her selfe against the biting of Vipers, by eating of favorie. Beares by eating of Pismires, expell that poison that they have contracted by their use of Mandrakes. And for correction of that drowzinesse and sloth which growes upon them by their long sleepe in their dens, they eate the herbe *Aron* (i) Cuckepint. But the Art they use in the entising and catching of Pismires is very pretty, They goe softly to the holes or hilles of the Pismires, and there lay themselves all their length upon the ground, as if they were dead, hanging out their tongue wet with their foame, which they draw not againe into their mouth, before they feele them full of Pismires, which are intised by the sweetnesse of the foame: And having taken this as a purging medicine, they expell by the guts, those ill humors wherewith they were offended. Wee see that Dogges give themselves a vomit, by eating of a kinde of grasse, which is from thence called Dogge-grasse. Swine, when they finde themselves sicke, will hunt after smalt or river lobsters. Stockdoves, Blackbirds, and Partridges, purge themselves by bay leaves. Pigeons, Turtels, and all sort of Pullen, disburden themselves of grosse humors, by taking of Pellitory of the wall. The bird Ibis (being not much unlike the Storke) taught us the use of Clusters. For when he finds himselfe oppressed with a burden of hurtfull humors, he fills his bill with saltwater, and so purgeth himselfe by that part, by which the belly is best discharged. The invention of the way of removing the Cataract of the eye, wee must yeeld unto the Goate, who by striking by chance against the thorny bushes, pulls off the Cataract which hinders the sight, and covers the ball of the eye, and so recovers his sight. The benefit of Phlebotomie, we owe unto the Hipporamus or River-horse, being a kinde of Horse, and the inhabitant of the river Nilus; who being a great devourer, when hee finds himselfe surcharged with a great deale of bloud, doth by rubbing his thigh against the sharpe sands on the bankeside, open a veine, whereby the superfluous bloud is discharged, which he stoppeth likewise when it is fit, by rowling himselfe in the thicke mudde. The Tortois having chanced to eate any of the flesh of a Serpent, doth make *origanum* and marjerom her Antidote. The ancients found helpe from brute beasts, even against the dreadfull and none-sparing force of lightning; for they were of opinion that the wings of an Eagle were never stricke with lightning, and therefore they put about their heads little wreathes of these feathers. They were perswaded the same thing of the Scale, or Sea-calse, and therefore were wont to encompasse their bodies with his skinne, as a most certaine safeguard against lightning. It were a thing too long, and laborious, to speake of all those other muniments of life and health (observed here and there by *Aristotle* and *Plinie*) which we have learnt of brute beasts. I will therefore end this Chapter, after that I have first added this; That we are beholding to beasts not onely for the skill of curing diseases, and of preservation of health, but for our soode, our raiment, and the ornament and beautifying the bodies.

Of the Faculty of brute Beasts in Presaging.

THe first knowledge and skill of Prognostication, and observation of weather by the Aire, was first delivered unto us from beasts of the land and water, and from fowle. For we see in daily observation, that it is a signe of change of weather, when Lambes and Rammes doe butt at one another with their hornes, and playing wantonly doe kicke, and keepe up their heeles. The same is thought to bee presaged when the Oxe lickes himselfe against the haire, and on the sodaine fills the Aire with his lowing, and smells to the ground, and when he feedes more greedily than he used to doe. But if the Pismires in great multitudes fetch their prey so hastily, that they runne and tumble one upon another in their narrow pathes, it is thought a signe of raine; As is also the busie working of Moales, and the Cats rubbing and stroaking of her head and necke, and above her eares, with the bottome of her feete. Also when Fishes play and leape a little above the water, it is taken for a signe of raine. But if the Dolphins doe the same in the sea, and in great companies, it is thought to presage a sodaine storme and tempest. Whereby the Marriners forewarned, use all care possible for the safetie of themselves and their shippes, and if they can, cast Anchor. And it is sufficiently knowne what the louder croaking of Frogges than ordinary portends.

What the butting of Rams signifies.

Presages of raine.

The signe at sea of a storme at hand.

But the facultie of birds in this kinde of presaging is wonderfull. If Cranes flie through the aire without noise, it is a signe of faire weather, and of the contrary, if they make a great noise and flie stragglingly. As also if Sea-fowle flie farre from the sea, and light on the land. The crie or scritchling of Owles portends a change of the present weather, whether foule or faire. *Plutarch* saith, that the loude cawing of the Crow betokens windes and showres, as also when he flappes his side with his wings. Geese, and Duckes, when they dive much, and order, and prune, and picke their feathers with their beakes, and crie to one another, foretell raine; and in like manner Swallowes when they flie so low about the water, that they wet themselves, and their wings. And the Wren, when he is observed to sing more sweetly than usuall, and to hop up and downe. And the Cocke when he chants, or rather crows presently after the setting of the Sunne. And Gnats, and Fleas, when they bite more than ordinary. If the Herne soare aloft into the aire, it betokeneth faire weather, if on the contrary he flie close by the water, raine. If Pidgeons come late home to the Dove-house, it is a signe of raine. If Bats flie in the evening, they foreshew wet weather. And lastly, the Crocodile layes his egges in that place, which must be the bounds of the overflowing of the river Nilus; And therefore he that first meetes with these egges, tels the rest of the countrie people, and shewes them how high the floud will rise, and what inundation it will make upon their grounds. A thing most worthy of admiration, that in this monster, there should be that strong facultie of presaging.

The Crocodile by laying her egges, shewes the bounds of the increase of the river Nilus.

Of the Industry of Fishes.

MAny sea-Fishes, when they feele a tempest comming, doe gravell or balast themselves, to the end they may not be tossed up and downe at the pleasure of the waves. Others when the fury of the sea is at the hight, hide themselves in the holes of rockes. But in that they swim against the streame, they doe it, for this cause and reason, that the force of the streame, and the floud may not take from them, and strike off their scales, and that their gills may not fill with water which would hinder their swimming; and intercept their respiration. As by the same advise Cranes flie against the winde, whereas if they should flie downe the winde, their feathers would be displaced and broken, and they would not be able to flie.

How Fishes provide for their safetie against a storme:

How they swimme against the streame,

Of the industry of Birds in the building of their neasts.

Of what
things birds
build their
neasts.

In what shape.

With what
care Spar-
rowes breed
their young.

THe industrie of Birds in the building of their neasts, is such, that it doth farre exceede the art and skill of all Mafons, and Architects. From whence it is become a Proverbe, *That men know, and can doe all things but make Birds neasts.* They are built within with wooll, and feathers, and such kinde of soft things, which are as a kinde of a pallet for the young ones. Swallowes build their neasts in a round forme, that they may be the more firme, and lesse subject to be hurt by any thing that shall strike against them, and likewise more capacious. They chuse their matter out of dirt and chaffe (interlacing it with many strawes) as it were their plaster, or lime. Those that build in trees, doe make choise of the soundest boughes, as if they meant to have them as a sure foundation for the building which they should erect thereon. The Cocke and the Henne doe by turnes sit over their egges, and likewise fetch their meate, interchanging each others labour, neither doe they ever forsake their young, before they are able to get their owne living. I had at my house a great number of Sparrowes neasts in earthen pots, And when the young ones begun to waxe pretty bigge, and to be covered with feathers, I made the whole neast be taken down, and set upon the ground, that I and my friends might delight our selves in beholding the care of the old ones in the feeding of their young, for they feede them every one in order, skipping none, neither will they (to the wrong of the rest) give one two parts, although he gape, and be importunate for it.; dividing most justly to every one his owne share, according to the exact rule of distribution. And often times for experiment, I would make triall with a strange Sparrow of the same age, laid neere, or put among the rest of the young ones, whether the old ones would feede the stranger, as if it were legitimate. But this as a stranger and a bastard they would suffer to starve, skipping it when it gaped after the meate. And in like manner Lambes and young Kiddes doe in the fields, in the midst of a great flocke, runne every one to his owne damme, who being most certainly able to distinguish betweene the legitimate and a bastard, will not suffer her selfe to be suckt but by her owne young.

Of the industry of Spiders.

How the
Spiders weave

How they
catch their
prey.

THe Spider spinnes her web with wonderfull artifice, hanging and fastening it to every tacke or stay that is nigh, drawing of his thread, and running upwards, and downwards, and every way. And although the diligence of the chamber maid beates downe, and marres this pendulous and new begunne worke, yet her seate and her hold, the Spider keepes still, neither is she, or will she desist from the worke shee hath begunne, but in a very short time, weaves a great deale more unto the ruines of her former worke, than can bee unweaved againe with much labour. So that from hence all cloth and linnen Weavers, all imbroiderers, and workers with the needle, (you will easily thinke) have learnt their Arts, if either you observe the exactnesse of the weaving, the finenesse of the thred, or the continuation and indissoluble knitting together of the whole web; for being abrupt and troubled with no ends of threds at all, it resembles a thinne membrane, annointed with a kinde of glew, wherewith when the prey is entangled, the Spider runnes presently in, and as it were drawes her nets, and infolds, and takes the captive after the manner of huntsmen. If this were not daily scene with our eyes, it would be thought fabulous.

Of Bees.

Bees chuse
themselves a
King.

I cannot passe in silence the great industry of Bees. For having established a kinde of Weale-publique, they make election of a King, who is such a one, as in proceritie of body, and excellencie of feature, exceedeth all the rest. He is remakeable by his short wings, his straight legges, his grave gate, and in stead of a Diadem or regall Crowne, either he hath no sting, or else doth not use it, which is the Artillery of the rest. He never goeth unattended out of the hive, but alwaies invironed with a princely retinue,

retinue, the rest of his traine following after, neither goes he at any time abroad, but upon urgent affaires which concernes the whole state. His progresse is forewarned by the voice and sound of trumpets, and as it were with singing, and they all draw nigh. Every one gets as neere to his person as he can, and when he is weary with flying, they all beare him up with thir owne bodies.

On what place soever he alighteth, there they forthwith pitch their tents. If hee chance to die, they goe not abroad to feede, but stand all mourning round about the corps; then carrie him out of the hive, and (as it were) follow his hearse and bury him, and lastly, having with solemnity performed all the funerall rites and obsequies, they chuse themselves another King, for without a King they cannot live. He then taketh care of all things, having his eye every where, whilest that the rest intend the performance of the worke. And supervising all, giveth them encouragement, and chastiseth negligence. For their time of going forth for foode, they chuse a cleare and faire day; for they have a naturall facultie of presaging of the weather. They are such observers of iustice and equitie, that never, either with their sting, or by any other way, doe they molest any creature, neither doe they exercise and prepare their speares against any, but for the safegard of themselves and their hives.

Their pitching their tents.

Their obsequies for their dead King.

Their justice.

Of the care of Bees.

They manage and order their affaires in this manner, in the day time they appoint before their gates a station of watchmen, and guarders. In the night, they rest from their labours, so long, till that one (who is appointed to this charge) by one or two hummes, as by a sound of a Trumpet, rowseth all the rest. Then come they together to observe what is the state of the weather, which if they foresee will bee faire, then abroad goe they into the fields, and pastures. Some therefore bring into the hive little fascicles of flowers on their thighs, others water in their mouth, and others a dewey moisture gathered on their bodies. These are met by others, who receive their burdens, which they dispose in their due and proper places. Those that are sent out into the fields for foode, are the youngest and the smallest. And therefore if the winde chance to rise any thing high, they expect untill it cease, and that the force and violence thereof bee over. But if it continue violent, then doe they ballast themselves with a little stone flying close by the ground, to prevent their being driven out and fro by the force of the winde. They are exceeding diligent in all their businesse, and doe punish the sloth of the lazye oftentimes with death. Some of them are the builders, others polish the building, and the rest bring in their materials.

Their watch.

Their divers imployments.

The building in their arched hives is with wonderfull artifice, being made with two doores, one to come in, and the other to goe out at. They have all things alike, least that the inequality, either of their food or labour, should give occasion of dissention. Their care is, that their houses may shew both state and handfomnesse. Idle droanes, borne for nothing but to eate, and consume the fruits of their labours, they chase from their hives. Those that chance to lose their stings, are utterly disabled, and in a short time their guts come out that way, and they die. They bring to their owners wonderfull increase of wax and honey.

They punish sloth with banishment.

Aristomachus the Philosopher doth boast, that for fiftie eight yeares together, hee had with great care beene a nourisher of Bees, onely that he might the better attaine to the knowledge of their state and condition.

Aristomachus a diligent observer of Bees.

Of Pismires, and Ants.

Neither truly is the industry, diligence, and experience of the Pismire lesse worthy of admiration, than that of the Bees. Insomuch as that *Salomon* bids the sluggard to take an example of diligence from the Pismire. Truly if experience did not witnesse it, it would seeme incredible, that so small a creature should be able to store up such abundance of corne, to dispose and manage her affaires in that good order

Lib. 11. C. 30

Wonderfull
care.

order that we see she doth. *Plinie* saith, that they have among them the forme of a well governed and well ordered common weale. For how pretty a sight it is to see them, when they seize upon a graine which they have a minde to carrie away, how they set to it, and lift it with head and shoulders. And how least the corne which they carrie to their store-house, should put forth and grow, they bite it at one end. If it be so bigge that they cannot carry it into their little hole, they divide it in the middle. If it be dampish, they lay it out to drie in the Sunne and open aire. When the Moone is at the full, they follow their worke in the night, when shee doth not shine, they take their rest, whereby they shew themselves to have some knowledge of heavenly things. *Plinie* affirmeth that they have their set Faires and Markets, whither they come in great companies, and where they use to establish leagues of amitie and friendship one with another. And when one markes them well, would hee not thinke that they were in conference one with another, and that they did discourse among themselves of their businesse? Doe wee not see that the often trampling of their little feete doth weare a path even upon hard flint stones?

There is no-
thing but may
be attained by
diligence.

From whence wee may note, what in all kinde of things is the effect of assiduitie. They say also that they performe the rites of buriall one unto another, after the manner of men. What words shall I use (saith *Plutarch*) to expresse sufficiently the diligence and industry of the Pismires. There is not among all the great things in nature, a sight of greater wonder than these. For in the Pismires are seene the markes of all vertue. Their great meetings argue that they maintaine a kinde of friendship.

The formes of
all vertues ex-
prest in Pism-
mires.

Their alacritie in the undergoing of their laboures, seemes to shew their fortitude and magnanimity; and lastly, they are eminent examples of temperance, providence, and justice. Their mutuall charitie appeareth in this, that if one of them that is not loaden meets another (in one of their narrow paths) that is, hee will give him the way, that hee may the better goe on in his intended journey. They say that the first entrance into their hole, is not straight, but full of many diverticles and crooked paths, which all end, which will bring you to three little cells; in one of which they have their conventicles, in the other they lay up their provisions, and in the third they bury the carcases of their dead. This doth *Plutarch* speake concerning Pismires.

Of Silke-Wormes.

With the industry of these creatures, I shall not unfitly joyne that of the Silkewormes, of whose paines and care, both in the making of their nests, and the spinning of their threed and bottomes (wherewith Kings are so magnificently adorned) Philosophers have written very strange things.

Diligence the
mother of
wealth.

And who can chuse but wonder at those great endowments of skill and knowledge, and that exceeding industry, (the mother of so much wealth) in the little body of so small a creature? The providence therefore of God, doth not onely appeare in this, that hee hath adorned each creature with a peculiar and proper endowment, but in this especially, that on the least creatures of all, hee hath bestowed the greater portion of skill, industry, and ingenuity to supply their defect of bodily strength.

Of the love of Beasts one towards another and
to their young.The industry
of Partridge
in preserving
their young.

Plutarch writeth; That all kinde of creatures beare a singular love, and have a kinde of care of those thatt are generated of them, and the industry of the Partridges, this way is much commended; for during the time that their young ones are weake and unable to flie, they teach them to lie upon their backs, and to hide themselves among the cloddes on the ground, that so being almost of the same colour, they may not be discerned by the Faulkoner. But if notwithstanding, they see
any

any body comming, and that hee is neere them, they doe with a hundred dodges and stoopings of themselves, as if they were wearie with flying, entise him away from their young to follow after them, and when they have their purpose, they then, as if they had recovered some fresh strength, fly quite away; who can but wonder at this both affection and subtilty?

Neither are those things lesse wonderfull that are reported of Hares, for when they would goe to their feate, they sever their young, and commit them to the trust of divers places, it may be two acres asunder one from another, least peradventure, a Huntsman, a dogge, or any man should chance to come that way, and they might be in danger to be lost at once. And then after they have traced up and downe, hither and thither, and every way that the dogges may not trace them, nor the Huntsman pricke them, they take a leape or two, and leape into their formes.

How Hares provide for themselves and their young, for feare of hunters.

Nor inferior to this is the craft of the Hedghogge, for when the Foxe pursueth him, and is now at his heeles, hee rowles himselfe up in his prickles like a chesnut in the outward shell, so that every part being rounded and encompassed with these sharpe and dangerous prickles, hee cannot be hurt. And so saves himselfe by this tricke; for his young he provides in this manner.

In the time of Vintage he goes to the vines, and there with his feete hee strikes off the boughs and the grapes, and then rowling his body makes them sticke upon his prickles, and so doth as it were take his burthen upon his backe, and then returns to his hole; you would thinke that the grapes did move of themselves; the prey hee devides betweene himselfe and his young.

The care of the Hedghogge to provide for her young.

In Florida part of the West Indies they have a beast, which for the variety and deformitie of it I cannot passe over in silence; The natives call it Succarath, the Canibals, Su. It keepees for the most part about the rivers, and the sea-shore, and lives by

prey. When hee perceiveth that hee is pursued by the Huntsman, hee gets his young ones upon his backe, and with his taile, which is very long and broad, he covereth them, and so flying, provideth both for his owne, and their safetie; neither can he be taken by any other way but by pits, which those Savage men use to digge in the places neere which he is to runne, into which at unawares hee rumbles headlong. This Picture of him here, I drew out of *Thevets Cosmographic*.

Tom. 2. lib. 23 cap. 1.

Of the affection of Birds, and of Dogges, towards their Masters.

THe young Storke provides for the old which is disabled by age, and if any one of their equalls come to any mischance, that hee is not able to flie, they will give him their assistance, and beare him on their backs and wings. And there-fore

The picture of Storke.

fore this affection and piety towards the old ones, and as it were brotherly love towards their equals, is commended in the Storke.

The Henne in any kinde of danger gathers her chickins under her wings, and as it were with that guard, defendsthem as well as shee can. For their sake shee exposeth her selfe to the crueltie of the fiercest beasts, and will flie in the eyes of a dogge, a Wolfe or a Beare, that by chance offers to meddle with her chickins.

The fidelity
of Dogges.

But who is there that doth not admire the fidelitie and love of dogges towards their Masters, whereby they recompence them for their keeping? A dogge will never forsake his Master, no, if he be never so hardly used. For there is no man can finde a stick hard enough to drive that dogge cleane away from him which hath once taken a love to him. There is no kinde of creature that doth more certainly and readily remember his master, hee will know the voice of all the household, and of those which frequent the house. There cannot bee a truster keeper (as *Cicero* himselfe saith) than a Dogge is; I speake not of their faculty of smelling, whereby they follow their Masters by the foote, and finde them, neither doe I speake of those infinite examples of the fidelity of Dogges, which were too long to rehearse.

Doves free
from adultery

Pidgeons, as well the Cocke as the Henne, although they are all very venereous, yet they know no adultery, yea and the Henne will beare with the frowardnesse of the Cocke, neither will she ever leave him, but reconciling him unto her by her officious diligence, bring him to his wonted dalliance and kisses, neither is the love of either of them lesse towards their young.

Turtles never
couple twice.

There is the like mutuall bond of love betweene Turtles, for if one of them die, the survivor never solicites Hymen more, neither will he ever chuse other seate than a dry withered bough.

*Of the strength, piety, docilitie, clemency, chastity,
and gratitude of Elephants.*

Among the beasts of the field there is none more vaste, more strong, or more to bee feared, than the Elephant. His strength is sufficiently shovne by those towered Castles of armed men, which hee carries, and fiercely rusheth with into the battell. The Romane souldiers being otherwise of undaunted spirit, yet in that battell which they fought against *Antiochus* being terrified with the vastnesse and immanity of these bodies which they had never before seene, presently turned their backs and fled, which notwithstanding, it is a wonderfull thing what stories naturall Philosophers tell of the vertues of the Elephant.

Lib. 8. cap. 1.

The religion
of the Ele-
phant.

Plinie writeth, that an Elephant commeth very neere to the understanding that men have, and that hee hath a rude kinde of knowledge of language; that his facilitie and obsequiousnesse is wonderfull, that his memory in the performance of his wonted duties, is no lesse wonderfull. And for Religion (*Plutarch* saith) that they pray unto the gods, and sprinkle and purge themselves with salt water, and that with great reverence, they worship the Sunne at his rising, lifting their trunks up towards heaven, for want of hands. *Plinie* addeth, that they doe with the like reverence worship the Moone and the Starres. For it is related in the Histories of the Arabians, that at a new Moone the Elephants goe by troupes downe unto the rivers, and there wash themselves with water, and being thus purged, kneele downe and worship the Moone, and then returne to the woodes, the eldest going first, and the other following after according to their age.

Plinie lib. 8.
cap. 5.

Plutarch reporteth, that it happened once, that among the Elephants which were taught at Rome against the Panegyricke shewes, there was one that was something dull, and not so docile as the rest, which made him be despised by his fellowes, and often beaten by his master. But that this Elephant, that he might supply by diligence what he wanted in wit, was oftentimes observed in the night, by the light of the Moone, to be practising and conning what he had learnt of his Maister in the day time. For they were wont to bee taught to make letters, and also to present garlands

garlands to the spectators; and other such like trickes. But they can never bee brought to goe aboard a shippe, to bee carried over the sea into any strange land, unlesse their Master give them his word to assure them that they shall

returne againe to their owne native soile. They never hurt any one that doth not first provoke them. They never gender but in private out of sight, an argument of their modestie.

Of the Lamprey.

Least that the heat of affection may seeme to lie quenched under the waters, let us by one example, (it were an infinite thing to speake of all) see in what kinde of mutuall love the creatures of the water come short of these of the land. The Lamprey of all the creatures of this kinde doth worthily beare the praise for its pietie towards those of whom it was generated, its affection towards those that are generated of her; for first she breeds egges within her, which in a short time after are spauned. But shee doth not as soone as her young ones are formed and procreated, bring them straight way forth into the light after the manner of other fishes, that bring forth their young alive, but nourisheth two within her, as if shee brought forth twice, and had a second broode. These she doth not put forth before they are of some bignesse, then she teacheth them to swimme and to play in the water, but suffers them not to goe farre from her, and anon gapes and receives them by her mouth into her bowells againe, suffering them to inhabite there, and to feede in her belly so long as shee thinkes fit.

*That Savage, or brute beasts may
bee made tame.*

*Cosmograph.
Tom. 2. lib. 19.
cap 7.*

Thevet reporteth, that the Emperour of the Turkes hath at Caire (it was once called Memphis) and at Constantinople, many savage beasts kept for his delight, as Lions, Tigers, Leopards, Antilopes, Camels, Elephants, Porcupines, and many other of this kinde. These they use to leade about the citie to shew. The masters of them are girt with a girdle, hung about with little bells, that by noise of these bells the people may be forewarned to keepe themselves from being hurt by these beasts. But in hope of reward and of gifts, they shew them to Embassadours of strange nations, before whom they make these beasts doe a thousand very delightfull trickes, and in the interim, they play their countrey tunes and musicke upon their pipes, and other instruments, and make many sports in hope of gaine.

That Fishes also may be tamed.

But it is far more wonderfull, that the creatures of the water should be made tame, and be taught by the Art of man. Among which, the chiefeft are held to be the Eele. The same things also are reported of the Lamprey. For wee have it recorded, that *Marcus Crassus* had a Lamprey in his Fish-poole, that was so tame, and so well taught, that he could command her at his pleasure. Therefore as a domesticall and tame beast he gave her a name, by which when he called her, she would come. And when this Lamprey died, hee mourned for her in blacke, as if shee had beene his daughter. Which when his Collegue, *Cnaeus Domitius* objected to him, by way of reproach, he replying, told him, that he had buried three wives, and had mourned for none of all them three.

*That men were taught by beasts to polish, and to whet their
weapons, and to lie in ambush.*

Souldiers are carefull to keepe their weapons from rust, and therefore they carrie them to the Armorers to be polished. But in this care, many beasts are nothing inferior unto them; for Boares whet their tuskes against they fight. And the Elephant knowing that one of his teeth is doubled with digging at the rootes of trees to get meate, keepeth the other sharpe, and touches nothing with it, preserving it for his

his combate with the Rhinocerot his enemy ; but the craft of the Rhinocerot is very remarkable, that being in continuall enmity with the Elephant, at the time

The craft of
the Rhinocerot
about to fight
with the Ele-
phant;

when hee prepares for the battell, he whets his horne against a rocke, as if it were with a whetstone; nor (if he can chuse) will he strike any other part of the Elephant but the belly, because he knowes that part of the Elephant is so tender, that it may be easily pierced. This beast is in length equall to the Elephant, but in height hee is inferior unto him, by reason of the shortnesse of his feete; he is of a palish yellow colour, and full of many spots.

*Of the Lion, the Ichneumon, and those other beasts
which are not easily terrified.*

The provi-
dence of the
Lion in his
going.

THE Lion when hee goes, hath his clawes alwayes clutched, and as it were put up in their sheathes, not onely because hee would leave no marke of his feete, whereby hee may bee traced and so taken, but because by continuall walking, hee should weare off, and blunt the points of his clawes. Bulls when they fight charge one another with their hornes, and like valiant souldiers, provoke, and animate one another to the battell.

The greatest
are terrified
by the least.

The Ichneumon seemes to imitate the most valiant souldier in his preparation, and accesse to battell, for hee bedawbes himselfe with mudde, and doth as it were buckle and make tite his armour; especially when hee is to encounter with the Crocodile; who although hee be a vaste beast, is put to flight by this little creature. And this truly hath beene observed to bee by the singular providence of nature, that the most vaste creatures are terrified by the least things, and such from whence there can arise no danger; so they say the Elephant doth startle at the grunting of an hogge, and the Lion, at the crowing of a Cocke; although it be reported of the Lion that no feare can make him turne his face. These kinde of feares, terrors, and affrightments, arising upon light, and most ridiculous occasions, wee finde as well in the ancient as moderne Histories of our times, to have disperfed and put to flight mightie legions of souldiers, and most potent armies.

Of Cocks.

Cocks are
Kingly and
martiall birds.

COCKES are kingly birds, and therefore nature hath adorned them with a combe, as with a princely Diadem, and wheresoever they come, their magnanimity and courage makes them Kings. They fight with their beakes and their spurres; and with their martiall voice they fright the Lion who is otherwise the King of beasts.

Of Conies.

Conies have
taught us una-
dermining.

CONIES have taught us the Art of undermining the earth, whereby the most clostie Cities, and structures reaching the very skies, are by taking away their foundation levelled with the ground.

Marcus Varro writes, that in Spaine there was a towne, and that no meane one, which standing on a sandy ground was so undermined by a company of Conies, that all the houses tumbling and falling downe to the ground, the inhabitants were faine to depart and seeke new dwellings.

Of Wolfes.

The deceies
and ambushes
of Wolfes.

MEN have learnt the arts of waging warre from the Woulfes, for they come out by troupes, and lie in ambush neere the townes which they have appointed, and then one of them runnes unto the towne and provokes the dogges. And making as if hee runne away incites the dogges to follow him, untill he hath gotten them unto the place where their ambush lieth, which on a sodaine appeareth, and rusheth out upon them. And so they kill and eate all, or as many of the dogges as they are able to catch.

of

Of the Fox.

IN subtilty and craft the Fox exceedeth all other beasts; when in the chase the Doggs are at his heeles, he berayes and bepiffes his taile, and swings it in the face and eyes of the Dogges that follow him, and so blinding them, in the meane time gets ground of them. To fetch the Hens downe from their pearch he hath this devile, hee shakes and swings his taile upwards and downewards, as if hee meant to throw it at them; which they fearing tumble down, & he takes up one of them for his prey. His warinesse when he passeth over a River that is frozen is wonderfull, for he goes softly to the banck, and layes his eare to listen, if he can heare the noyse of the water running under the ice. For if he can, back he goes, and will not venter to passe over. The knowledge of which thing he could never meerely by his subtilty and craft attaine unto, but that of necessity hee must have some faculty of reasoning. ioyned with it, which by discourse and by proving one thing by another arrives at this Conclusion: Whatsoever is liquid and maketh a noyse is in motion, whatsoever liquid is in motion is not concrete and frozen, that which is not concrete and frozen is liquid, whatsoever is liquid will not beare a heavier body, whatsoever will not beare a heavier body, cannot with safety be adventured on; And therefore backe againe must I goe, and not passe over this River.

The craft of the Foxe.

The Foxe seemes to reason with himselfe.

His Sorites

Of Swine.

SWine, if in the woods, they heare any one of the same Heard with them crying out, they straight make a stand, and marshalling their forces haste all, as if they had beene warned by the sound of a martiall trumpet, to the assistance of their fellowes.

Of the fishes Scarus and Anthia.

PLutarch reports of the *Scari*, that when one of them chanceth to swallow a hooke and be taken, the rest of the same kind come in to his reskue, and shearing the Line with their teeth set him at liberty. But the readines of the *Anthia* to the mutuall assistance of one another, is yet more manifest, for by casting the Line upon which the hooke hangeth, on their backe, with the sharpnesse of their fins they cut it asunder, and so set free themselves and their captived fellowes.

The love of Fishes one to another.

Of the Pilot Fish.

THERE is great kindnesse betweene the *Pilot* Fish and the Whale. For although in bulke of body the Whale so farr exceed him, yet he leades the Whale and goes alwayes before him as his Pilot, to keepe him from running himselfe into any straight or muddy place, whence he might not easily get out. And therefore the Whale alwayes followes him, and very willingly suffers himselfe to be led by him, it being for his owne good. And in like manner he gets into the Whales mouth, and there lodging himselfe sleepes when he sleepes, and leaves him not either by day, or night.

The Whales pilot or guide.

Of Cranes.

CRANES when they are to take a long journey into some Countrey crosse the seas, put their company in so good order, that no Captaine can put his soldiers in better. For before they stir out of any place, they have as it were their trumpets to call them together, and encourage them to fly. They come together and then fly up on high, that they may see a far off, choosing a Captaine whom they are to follow. They have their Serjants to take care of their rankes, and keepe their nightly watches by turnes. Plutarch tells us that the Crane, which is appointed to stand

Cranes order themselves in rankes.

The sentinell Crane.

give

give way to nature and sleepe, she may be waked by the noise of the falling stone. The leader lifting up his head, and stretching out his long necke, lookes about him farre and wide, and gives warning to the rest, of any danger, that may befall them. The strongest leade the way, that they may the better with the flapping of their wings breake the force of the aire, and this they doe by turnes. And that they may the easilier prevaile against the force and opposition of the winds, they dispose their company into a wedge in the forme of the Greeke letter Δ or a triangle; and being skilfull in the starres they foresee when tempests are comming, and fly downe to the ground to keepe themselves from the injury of the approaching storme.

Of Geese.

The care of the Geese, that their gagling, doe them no harme,

THe Geese of Sicilie doe with great warinesse take care that by their ceeeking and their noyse, they doe not expose themselves to the rapacity of Birds of prey: (for *Plutarch* sayth) that when they are to fly over the hill Taurus, for feare of the Eagles that are there, they hold stones in their mouthes to keepe themselves from gagging, untill that they come unto a place where they may be secure.

Of Dragons.

The craft of Dragons fighting against the Elephant.

Lib. 8. cap. 11. and 12.

Neither are the Dragons lesse crafty; for thus doe they overcome those vaste and otherwise invincible beasts the *Elephants*. They lye in ambush and suddainly set upon the *Elephants* where they feare no such matter, and involve their leggs with the twines of their taile, in such sort, that they are not able to goe forward; and stop their nostrils with their heads so that they cannot fetch their breath, they pull out their eyes, and wheresoever they find the skin most tender, there they bite and sucke the blood untill they make them fall downe dead. *Pliny* sayth, that there are Dragons found in *Aethiopia* of ten Cubits long, but that in *India* there are Dragons of an 100. foot long, that fly so high, that they fetch Birds and take their prey even from the midst of the cloudes.

Of the Fish called, the Fisherman.

The craft of the Fisherman-fish in taking her prey.

THis Fish is called the Fisherman, because he hunts and takes other Fishes, which he doth almost by the same cunning which the *Cuttell* uses; for he hath hanging at his throat a certaine bagge like the Wattells of a Turkeycocke. This when hee listeth he casteth out, and layeth before the little fishes for a baite, and then by litle and litle drawes it up againe untill he catch for food the little fishes seazing upon it as a prey.

Of the Cuttell Fish.

The craft of the Cuttell to save her selfe.

Lib. 9. de Hist. animal. Cap. 37.

VVonderfull is the craft of the Cuttell Fishes, for they carry a bladder at their necke full of a blacke juice or Inke, which they poure forth as soone as they feele themselves taken; that so they may blinde the eyes of the Fishermen, as *Plutarch* saith; and as *Aristotle* witnesseth, they with their long fangs doe not onely hunt and take little Fishes, but oftentimes also Mulletts.

Of the Armes or weapons of brute beasts.

BRute beasts are naturally so furnished with armes, that they have no neede to get, make or borrow in any other place.

Cesius. Tom. 1. lib. 10. cap. 10.

And some of them neverthelesse are so furnished with such armes that they captivate those which hold them prisoners; an example of this is the *Torpedo*, which doth not onely hurt by touch, but also by the net being betweene, he breathes such a quality from him, as stupifies the hands of the Fishermen, so that they are forced to let goe their nets, and so let him goe; moreover if it touch a ship it makes it stay. *Theophrastus* writes, that the *Persian* bay towards *Arabia* nourishes a Fish equall in length and thickness

thicknesse to a Carpe, on every side encompassed with sharpe and strong pricks, like our Porcupine, with which hee fights against all kinds of fish. If a man chance but to be lightly hurt either with theie or his teeth, he will dye within 24.houres.

Of the fish Vtelif.

Hee saith moreover, that as he was carryed by force of tempest through the Atlanticke Ocean, he saw this fish having as it were a Saw in his forehead of three foot long, and foure fingers broad, armed on each side with sharpe spikes; They call it *Vtelif* in their Country speech.

Of the fish Caspilly.

There is another fish to be scene in the Arabian Gulfe, which the Arabians call *Caspilly*, its two foot long and as many broad, it hath a skin not much unlike a Dogfish, but armed with spikes, one whereof he carryes in his forehead a foot and halfe broad, in sharpenesse and force of cutting not much short of a graver or chissell: with this weapon when she is opprest with hunger she assailes the first fish shee meets, neither doth she give over before she carry her as a prey, *Tom. 1. lib. 5. cap. 2.* whither she please, as *Thevet* saith he hath scene.

Of Crabs.

Crabs and Lobsters though in the quantity of their body they be but small, yet they use their forked clawes before, not onely in feeding but also in defending themselves and assailing others.

Of the Docility of Beasts, and first of the Dog.

Beasts are apt to learne those things which men desire, whereby they shew themselves not wholly void of reason. For Dogges, Apes and Horses learne to creepe thorough the Iuglers hoopes, and rise on their hinder feet as though they would dance. *Plutarch* tells, that a Iugler had a Dog which would represent many things upon the stage besitting the occasion and argument of the play; amongst the rest, hee exceeded all admiration in that, that taking a soporifick medicine, hee excellently feigned himselfe dead; for first as taken with a giddinesse in his head he begun to tremble, then presently fell down, and lying on the ground, as it were contracted his dying members, and lastly as if truely dead he waxt stiffe; and moreover suffered himselfe diversly to be fitted according to divers parts of the Theater, the fable so requiring. But when he, by those things that were said and done, knew it was time to rise, he first begun to move his legs by litle and litle, as if hee had been wakened from a sound sleepe; then presently with his head a litle lifted up, hee looked this way and that way to the great admiration of all the beholders, and finally rise up and went familiarly and cheerfully to him he should; the which sight the Emperour *Vespasian* (who was then present in *Marcellus* his Theater) never saw any which more delighted him.

The wonderfull docility of Dogs.

A spectacle full of admiration and mirth

Of the Ape.

An Ape is a ridiculous Creature, and which makes men much sport, in imitating their actions. There hath beene seen an Ape which would pipe and sing, and besides dance and write, and endeavour to performe many other things proper to men. I remember I saw in the Duke of *Somes* house a great and curst Ape, who because he much troubled many, had his hands cut off, who suffering himself to be cured, when the wound was cicatrized, he grew more mild and docile. Wherefore cloathed in a greene coate, and girt over his loines with a girdle, he carried hanging therat a case of spectacles, a paire of knives & a childs handkercheife. He was committed to the charge of the Master Cooke to teach, because he had taken up his lodging in the Chimney corner, he

Gal. lib. 1. de usu partium.

hee was taught many pretty tricks and feates. If at any time hee swarved from his doctrine and precepts, in a trice the whip was upon his back & loines, and much was abated of his daily allowance, for as *Persius* saith, The belly is the master of Arts and sharpener of wit. By these means he profited so, in a short time, that he much exceeded all the Apes of his time in the glory of his wit; & there was none counted more skilfull in leaping and dancing to the pipe, running up a pole and nimbly leaping through his Masters legs. To conclude, he performed all the actions of a strong Ape, and very reverently carried up dishes with the waiters & servingmen, and made cleane the dishes and platters by licking, and did much other drudgery, so that he was commonly called Master *John Do-all*. At dinner and supper sitting in a chaire he said grace, and cast his eyes up towards heaven, and rouled them this way and that way, and smote his breast with the stumps of his hands with much lamentation, and imitated prayer by the gnashing, or beating together of his teeth. He would turne up his taile to any that offended him (for his coate scarce covered halfe his buttocks lest he should have filed it) he made much other pastime, alwayes going upright by reason of the cutting away of his hands, unlesse at any time through wearinesse he were forced to sit on his buttocks.

Of Ravenous birds.

The diligence of Faulconers in training up their Hawkes.

BVt let us take a veiwe of Faulconers teaching ravenous birds, how with swift wings carried aloft into the Aire, they may seaze upon other Birds and cast them downe dead to the [ground; in performance whereof, they often too freely soare up to the clouds so that they carry themselves out of the Faulconers sight, with a desire to sun themselves, neglecting in the meane time their designed prey.

The fight of the Herne and Falcon.

The *Herne* when she sees her selfe kept under and below the *Falcon* carried up by his strong wings with a mervellous swiftnesse, with her beake, which is long & sharpe, hid under her wings and turned upwards, she receives the *Falcon* blinded with the heat of fight and desire of prey, carelesly flying downe and rushing upon him; so that he often strikes him through the gorge, so that oft times they both fall downe dead to the ground. But if the *Falcon* without harme escape the deceits by Arte & the happy turning of his body, and the *Herne* be not cast downe, the Faulconer calling her backe with never so loud a voyce, yet by setting up her Feathers she dares her to the pretended fight.

Of the Camels.

Camel both tame and wilde.

The easie and not chargeable keeping of Camels.

Camels know when they have a sufficient load.

Camels both to carry burdens and to ride upon.

THe *Camell* is a very domesticall and gentle beast, and which is easily tamed and taught all kind of obedience and service; although some of them are cruell wilde and troublesome by biting and striking such as they meet, no lesse than vntamed horses. There is no neede to house them in the night, for they may be left in the plaine fields in the open and free aire, feeding upon the grasse and trees and cropping the tops of the thistles, neither in the morning doe they any whit the worse under-goe or carry their burdens. They are not put to carry burdens before they be foure yeare old. The Arabians geld them young, that they may enjoy their labour the longer, neither being gelt doe they rage for love or desire of venery. At the putting in of the Spring they endure hunger and thirst for eight dayes; they are so durifull, that at the becke of the Turkish slaves, or but touched on the necke with a twigge, they presently kneele on the ground to take up their burden, neither doe they lift themselves up before that they finde they have a sufficient load layd upon them. Those which have but one bunch on their backe are of Africke; but such as have two bunches are of Asia, or Scythia. Those kinde of *Camels* that are the bigger are used to carry packes, but the lesser are used to ride upon, as our horses are. They love nothing so well as beanes, and yet they live content with foure handfulls of beanes for a day. The greatest wealth of the Arabians consists in *Camels*, and so they estimate their riches, not by the quantity of silver, or gold, but by the number of *Camels*. The Turkish Emperour (*Thevet* being the reporter) made a Captaine over the herds of his *Camels*, giving him a great troope, of African and Christian slaves, that they might be the better looked unto. I have heard it reported (saith *Thevet*) by certaine Arabian, African and Iewish Merchants who were present, at that time when *Sultan Selim* the first of that name, beseiged

beseiged Caire in Egypt (which in former times was called *Memphis*) that there

Mighty troop
of Camels.

was then in that Emperours army sixtie thousand Cammels, besides a mighty company of Mules.

That Birds have taught us muscall tunes.

To sing like a
Nightingale

THe Nightingales are sweet and excellent fingers, tuning rheir notes with infinite quaverings, and diversities of sounds, so pretily and sweetly, that humane industry can scarce equall the sweetnesse thereof, by so many muscall instruments; so that wee say hee sings like a Nightingale, who varies his voice with much varietie. In which thing Birds much excell men, because they have that admirall sweetnesse of singing from nature it selfe without any labour of learning; which men can scarce attaine to in any schoole of musicke, by having their eares a thousand times pluckt by the hand of a curst master.

That Beasts know one anothers voice.

The voice to
beasts is of the
same use, as
speech is to
men,

We are as ill
as deafe, when
we heare an
unknowne
language.

Beasts know one another by their voice, so that they may seeme to talke and to laugh together, whilest flattering with their eares, they plucke in their noses, with a pleasant aspect of their eyes; and as speech is given to men, so Birds have their naturall voice which is of the same use to them, as speech is to us. For all birds of the same species, as men of the same countrey, chant and chirpe to one another, when men understand not the speech of other men, unlesse of the same nation. Wherefore the Scythian tongue is no more profitable to one living in Egypt, than if hee were dumbe; nor the Egyptians understand it no more than if they were deafe: Wherefore an Egyptian is dumbe and deafe to a Scythian. This those which travell well understand how many dangers, how many troubles they undergoe, because they cannot expresse their mindes, and require things necessary for life. Wherefore to the assistance of this unprofitable tongue, we are compelled to call the rest of the members, and to abuse the gestures of the head, eyes, hands, and feete. Truly the condition of brute beasts is not so miserable, seeing that all of the same kinde where-soever they bee, may answer each other with a knowne voice. Truly if any should heare a Germane, Briton, Spaniard, Englishman, Polonian, and Greeke, speaking amongst themselves in their native tongues, not understanding any of them, he could scarce discern, and certainly judge, whether hee heard the voice of men or of beasts.

That Birds may counterfeit Mans voice.

Parrots are
wonderfull
imitators of
mans voice.

A talking Pie,

Lib. 2. Saturn.
cap. 4.

Inets, Larkes, Pies, Rookes, Dawes, Crowes, Stares, and other such like Birds, speake, sing, whistle, and imitate the voices of men, and other creatures. In this Parrots excell all other, being wondrous skilfull imitators of mens voices, and very merry, but specially when they have drunke a little wine.

Plutarke reports that there was a Barber at Rome, who kept a Pie in his shop, which spoke exceeding well, and that of her owne accord, none teaching her, when she first heard men talking together; shee imitated the voice or crye of all beasts shee heard, as also the sound of Drums, and the noise of Pipes, and Trumpets; to conclude, there was nothing which shee did not endeavour to imitate. There have beene Crowes that have spoken and articulately sung songs, and Psalmes, and that of some length. To which purpose the Historie of *Macrobius* is notable; for hee tels that there was one amongst those, who went forth for lucke sake to meete with *Augustus Caesar*, returning from the warre against *Antonius*, who carried a Crow, which hee had taught plainely to pronounce this salutation; *Salve Caesar Imperator augustissime*, that is, *God save thee, O most sacred Emperor Caesar*. *Caesar* taken with the noveltie of this spectacle, bought this obsequious Bird with a thousand pceces of silver. *Pliny* and *Valerius* have reckoned up amongst prodigies, Oxen and Asses that have spoken. I omit infinite other things recorded by the ancients, *Plato*, *Aristotle*, *Pliny*, *Plutarch*, and other Philosophers of great credite, of the docilitie of beasts, and their

admirable

admirable felicity of understanding. Which things, if untrue, these learned men would never have recorded in writing, lest so they might brand with vanity, (then which nothing is more base,) the rest of their writings to posterity in all ensuing ages.

*Of the Sympathy and Antipathy of Living creatures
amongst themselves.*

HAVING briefly described the understanding of brute beasts, it seemes not impertinent to set downe some things more worthy of knowledge, happening unto them by reason of Sympathy and antipathy; that is, mutuall agreement and disagreement, which happens not onely to them living, but also dead; by a certaine secret and hidden propertie, through occasion whereof some desire, other shun, and others prosequute one another even to death. In testimony whereof; The Lyon the king of beasts excelling all other in courage and magnanimitie, feares the Cocke, for he is not onely terrified by his presence, but also by his crowing being absent. So an Elephant feares a Hogge; but hee is so affraid of Mice and Ratts, that he will not touch the meat that is given him, if hee smell that it hath beene desired with such creatures. There is deadly hatred betweene the Elephant and Rhinocerot; yet when the Elephant is furious and angry, hee becoms quiet and calme at the sight of a Ram. A horse is so afraid of a Camel, that he cannot endure his sight. The Dog hates the Wolfe, the Hart flyes the Dogge. The Snake flyes from and feares a naked man, and followes him being clothed. There is deadly hatred between the Aspis and Ichneumon, for he when he hath rowled himselfe in the clay, dryes himselfe in the Sunne, and so being covered over (by doing thus diverse times) as it were with shells, or armour, he enters into Combat, stretching out his taile and presenting his backe, untill he get opportunity to choake his adversary, by leaping and fastening on her jawes, by which stratageme he also kills the Crocodile. The green Lizard is a capitall enemy to the Serpent, but most friendly to man, as *Erasmus* witnesseth by many historyes concerning that matter, in his dialogue of Sympathy and Antipathy. There is a great deale of hatred betweene a man and a Wolfe, which is most manifest by this, that if the Wolues first see a man, his voyce is taken away, and his intended cry hindered. If the Weasell intend to set upon the Aspis that most venomous Serpent, shee armes her selfe by eating Rue, as a most certaine Antidote. The Ape feares the Torpedo, as *Erasmus* manifests by a pleasant history in the forementioned Dialogue; where also he pretily shewes the deadly hatred betweene the Serpent called Areas and the Toad. The like hate is between the Owle and Crowes, so that the Owle dares not go out, fly abroad, or seeke her food unlesse by night. The water or River fowle are afraid of the Falcon; that if they but heare her bells, they had rather be killd with staves and stones, than take wing to fly into the aire. So the Larke yeelds her selfe to be taken by a man, least she fall into the talents of the Hobby. The Castrill, or Merlin is naturally a terrour to Haukes, so that they both shun his voyce and presence.

The Lion
feares a cocke.

A horse feares
a Camel.

Water fowle
feare the Falcon.

The enmity
betweene the
Kites and
Crowes.

The discord
betweene the
Lambe and
Wolfe is not
ended by deal.

The Kites are all at perpetuall enmity with the Crowes, wherefore the Crow alwayes gets away the Kites provision. All kind of Pullen feare the Foxe. The Chicken feares neither a Horse, nor an Elephant, but scarce hatched, it presently runs away at the voyce or sight of a Kite, and hides it selfe under the hens wings. The Lambe and Kid flye from the Wolfe when they first see him, nether doth death give an end to that hatred, but it superviues their funerall. An Experiment whereof (they say) is, that if one drum be headed with Wolves skinnies and another with Sheepes, and beaten up together, you shall scarce heare the sound of the Drum covered with sheepes skins. And besides, if you string one Harpe with strings made of sheepes gutts, and another with strings of Wolves gutts, you cannot bring it to passe, by any Arte, to make them agree and goe in one tune. It is reported from the experiments of many men, that if a Wolves head be hanged up on high in the place where Sheepe are, that they will not touch the grasse how good and fresh soever it be, nor rest quiet in any place, but tumultuously runne up and downe, untill all such kinde of terrour be taken away; The hate

H

betwixt

How to make
cheese that
Mice will not
gnaw.

betwixt Mice and Weasells appears by this, that if you mixe never so little of the braines of a Weasell in the rennet, with which you crudle you Cheese, the Mice will never gnaw or touch that cheese. The Linnet doth so hate the bird *Florus*, that both their bloods put into one vessell cannot be mixed together. A Wolves head hung up in a dovehouse, drives away Poll-Cats and Weasells. The Panther and Hyæna burne with so great hatred, that if both their skins be laid one against the other, the Panthers will shed the haire, the haire of the Hyæna remaining entire and not moved; which thing, they say, happens to the feathers of other birds if any one chance to tye them up in a bundle with the Eagles. Let these suffice for some few examples of many, of the Antipathy amongst beasts. But of the Sympathy, and consent of beasts amongst themselves, I thinke needlesse to write any thing, being it is sufficiently knowne to all, that one lay associates another, and the cruell Beares agree amongst themselves; and beasts of the same species doe wonderfully consent one with another.

That Man excels all beasts.

Man beares
Gods image:

INOW thinke it fit to assay to write of that excellency of man over beasts, which I have so long intended. Neither would I that Epicures and other too much naturall and materiate Philosophers, so take those things I have written of the endowments of beasts, as though we should thinke, there were no difference betweene man and beast. I had no such meaning, no such intention; but onely that man should not become too stately, or too ingrate in lesse acknowledging God to be the Author of so many benefits with which he abounds. For whatsoever we have largely spoken of beasts, yet there is no comparison betweene beasts and man, for there is too great a difference betweene them. For mans minde is adorned with religion, justice, prudence, magnanimitie, faith, piety, modesty, clemency, fortitude and other vertues as lights, which shine much more bright in man than in beasts. For they are sometimes all in some one man, each whereof are thought great in beasts. For seeing that man is made to the Image of God, it cannot be, how much soever he defile himselfe with the pollution of vices, that he can so obscure that inbred light, but that alwayes some beame of the divine wisdom will be inherent and shine in him. But although by collation to some beasts, hee may seeme a defective and weake Creature; yet no fortitude nor strength of beasts can be so great as to equall the fortitude of man. For God hath engraven in man the character of his divine virtue, by the assistance whereof, he might have all beasts under and obedient to him. And though by that we have formerly said, beasts may seeme to have a certaine shadow of reason, yet that small light is not fit for many and diverse uses, but there is onely given them so much providence, as should be sufficient for them and the preservation of their bodyes. But men have reason given them to crop or gather the fruits of eternall life, (as *Lactantius* saith) whereby it comes to passe, that man onely, amongst so many creatures, hath sense and understanding of divine things. Which *Cicero* thought to be knowne by that, because man onely had a certaine knowledge of God in his mind. Wherefore he was enriched by God with reason, speech and hands as helps for the performance of all his actions; moreover by his singular and almost divine wit he easily excels all brute beasts. For first, reason being his guide, he invented things necessary for life, fitly imposed names on the things invented besitting their natures, framed letters and Characters, invented all liberall Arts and handy-crafts, and found meanes to measure the Land and Sea. Hee hath observed and drawne into an Art the spaces of the Celestiall Globe, the distinctions of the Starres, the changes and orders of dayes and nights, of times and seasons, the risings and settings of Starres, and their power and effects over these lower bodyes. Lastly, he records in writing to perpetuall memory that which concernes his owne nature, or the nature of other things, the precepts and ordinances of life and manners, by which singular gift, we can now conferre with *Socrates*, *Plato*, *Aristotle*, and other Philosophers of ancient times, as if they were living.

Man hath gi-
ven names to
things.

What

*what benefit man hath by reason of his native
nakednesse and ignorance.*

BVt as Mans body is by nature naked and unarmed, so is his minde like a smooth table in which nothing is painted, nothing graven; but for helpe of his nakednesse he hath hands, and for supply of his ignorance, reason and speech. And by these three being as it were the ministers of infinite varietie of things, he clothes and defends his body with all things needful: & enriches his minde with the knowledge of Arts & sciences. Now if he had certaine weapons borne with him, he should use them only; if he should be borne skilfull in any Arte, he would meddle with none else. Therefore because it was more expedient to use all sorts of weapons with the hand, and be skilfull in all Arts; therefore he must be borne wanting and ignorant of all. *Aristotle* very wittily called the hand the instrument of instruments: in imitation of which speech, one may rightly affirme, That Reason is the Arte of Arts: for as the hand in worth exceeds the other instruments, because it can make, handle and fit them for use; so reason and speech, though names of no Arte, yet comprehend and encrease all Arts. Therefore man seeing he hath his minde instructed by Arte, that is, by reason; it is fit he should have his body defended with a weapon, or instrument, that is, the hand, which in agility and excellency should excell all other instruments. For so Man hath his hands instead of all weapons, which he may use in warre and peace as the instruments of all Arts; he wants not the Bulls horns, the Boares tuskes, the horses hooves, nor to conclude, any armes of any other beast. For by the benefit of his hands he can handle other armes farre more profitable and safe, as a Lance, Sword, Speare, halberd; but man also can use at some distance the bow, sling and handgun, when the horne and the hoofe cannot be used but neer at hand. But some may say; A Lion exceeds a man in swiftness of foot; what then? is man therefore inferiour to him? no for by the meanes of his hands and the guidance of his reason he bridling and riding upon a horse, out runs the Lyon, and being victor followes him to and againe as he himselfe pleases, or vanquished flies away, and from the horses backe as from a tower wounds the Lyon with what weapons he pleases. To conclude, man is abundantly provided with meanes, to defend himselfe from the violence of all other beasts. For this purpose he doth not onely harness himselfe as with brasen walles, but also makes ditches and Bulwarkes; he makes by the ministry of his hands all kind of weapons, weaves himselfe garments, casts into the water and drawes forth nets to catch fish; and to conclude, he performs all things to his owne contentment, and having that priuiledge granted him by God, he rules over all the earth; all things which lye hid in the bowells of the earth, which goe, or creepe upon the earth, which swim in the sea, and fly through the aire, or are any where shut up in the compasse of the skie, are in mans dominion.

*Gal. cap. 4. lib.
I. de usu partium*

*As the hand is
the instrument
of instruments
so Reason is
the Arte of
Arts.*

*Man under
God is the
King and Em-
perour of the
World.*

How wonderfull God hath shewed himselfe in making man.

Gods Deity and providence hath principally shewed it self in the creation of man; neither his so admired light hath so shone in the production of other creatures, seeing that God would have them to live and have their being, onely for mans sake, that they might serve him. Therefore man is, if we diligently consider all his endowments, a certaine patterne and rule of the divine majesty & (if I may so say) Artifice. For being made to Gods image, he is as it were his coine, exceeding the capacity of all humane understanding. Which seemed a just reason to the ancient Philosophers, that he should be called *Microcosmos*, or a litle world, because the particles of all things contained in the compasse of heaven and earth, are contained in his minde and body, that in the meane time I may in silence passe over his soule more great and noble than the whole world.

*Man is the end
of all mundane
things.*

*Man a litle
world, yea al-
most a great
world.*

Why Nature hath not given Man the facultie of persaging.

Man is not
obnoxious to
the Aire and
stars,

One man will
counterfeit
the voyces of
infinite varie-
ties of beasts,

The power of
Musicks.

THIS seemes the reason, that men by the instinct of nature doe not foresee the future seasons and dispositions of the heaven and aire; because, seeing they have received certaine sparks of prudence from God, by whose care and guidance they are led to the knowledge of things by no deceitfull but certaine judgment, being not obnoxious to the conditions and changes of times and seasons, as beasts are. Wherefore knowing all these airy changes to be placed under them, that is to say their minds, according as occasion serves, and their minds desire, they give themselves to mirth when the Aire is wet, stormy and darke, and on the contrary in a cleare and faire season to a sincere and grave meditation of things sublime & full of doubt. But beasts accommodating themselves to that disposition of the aire which is present & at hand, are lively, or sad, not from any judgment as men, but according to the temper and complexion of their bodies following the inclinations of the aire, and of the humors one while diffused, another while contracted. Neither ought we to blame man, because he can imitate the voyce of beasts, but rather much commend him, that he can infinitely wrest and vary one thing, that is his voyce; for men can barke like Foxes and doggs, grunt like hogs; whet and grinde their teeth like boares; roare like Lyons; bellow like Bulls; neigh like horses; knacke their teeth like Apes; howle like Wolues; bray like Asses; bleate like Goats and Sheepe; mourne like Beares, Pigeons and Turtles; Keeke and gaggle like geese; hisse like Serpents; cry like Storkes, caw like a Crow, and crow like a Cocke, clocke like Hennes; chatter as Swallowes and Pyes; sing like Nightingales; croake like Frogs; imitate the singing of Wasps and Humming of Bees; Mew like Catts. The singing of Birds scarce seemes to merit the name of Muscicall, compared to the harmony of men fitted and tuned with infinite variety of voyces. For with this they possesse the eares of Kings and Princes; provoke and temper their wrath and carry mens minds beyond themselves, and transforme them into what habits they please. But if those cruell beasts have any humanitie, they owe it all to man. For he tames Lyons, Elephants, Beares, Tigers, Leopards, Panthers and such other like.

Of the Crocodile.

A tame Cro-
codile.

Plutarch reports of the *Crocodile* (whose figure is here delineated) that being tamed, and taught by man, hee doth not onely heare mans voyce, and answeres to his call, but suffers himselfe to be handled, and opening his throate, lets his teeth be scratched and wiped with a towell. How small a part of Physicke is that, which beasts are taught by nature? Certainly nothing in comparison of man, who by the study and practise of a few yeares can learne at his fingers endes all the parts of Physicke: and practise them not onely for his owne, but also for the common good of all men. But why cannot beasts attaine unto the knowledge of Physicke so well as men? I thinke, because so great an Arte as Physicke is, cannot be attained unto by the dull capacities of Beasts.

In what sense
we said Ele-
phants had
religion.

But for that I have written of the Religion of Elephants, if I must speake according to the truth of the matter, wee cannot say they worship God, or have any sense of the divine Majesty. For how can they have any knowledge of subliming things or of God, seeing they wholly following their foode, know not how to meditate on celestiall things? Now for that they behold and turne themselves to the Moone by night, and to the Sunne in the morning, they doe not that as worshipping, or for that they conceive any excellency or divinitie in the Sunne; but because nature so requiring and leading them, they feele their bodies to rejoyce in that light, and their entralls and humors to move and stirre them

them to it. Therefore when we attributed religion to Elephants, we said it rather popularly, than truly, and more that we might exhort men to the worship of God,

than that we thought Elephants had any knowledge of divine worship implanted in their mindes.

*That man may attaine unto the knowledge of all voyces
and tongues.*

THe docility of mans wit is so great, and the facility of the body obeying that divine gift of wit such, that he is not onely able to learne to understand and speak the

Man not on-
ly the imitator,
but the inter-
preter of the
voices of beasts
and birds.

the tongues of diverse nations differing in so many peculiar languages; and not only to imitate and counterfeit the voyces of all beasts though so much different from man, which many flattering and juggling companions, followers of other mens tables, will doe; but also may be able to know and understand both what they pretend and signifie. In confirmation of which thing they cite the Philosopher *Apollonius* most famous in this kind of study and knowledge. He walking on a time amongst a company of his friends thorough the field, and seeing a Sparrow come flying and chirping much to diverse other Sparrowes sitting upon a tree, is reported, to have said to those which were with him: That bird, which came flying hither, told the other in her language; that an Asse laided with corne was fallen downe at the City gate, and had shed the wheat upon the ground. Wherefore *Apollonius* and all his friends which were with him went thither to see whether it were so, and found that it was so, as he had told them, and observed that the Sparrowes moved thereto by the comming of the other, were eating up the graines of Corne shed on the ground.

The unquench-
able desire
of learning in
man.

But for Crowes and Pyes artificially taught to counterfeit mens voyces, it is too small a thing, that for that cause they should contend with men. For they have quickly babled all they have learnt with longer cost and labour, tediously singing still the same song, and whatsoever they prate they doe it without sense, understanding or any reason for what they say. But man alwaies contemplating somewhat more high, still thinks of greater things than these present, and never rests. But burning with an infinite and endlesse desire of knowledge, hee doth not onely covet to know these things which appertaine to food and clothing, but by casting up his eyes towards heaven, and by the light of his minde, he learns and understands things divine. Which is so certaine an argument of the celestially originall of our soule, that hee which considers these things can no wayes doubt, but that we have our minds seasoned, by the universall divine understanding. But now it is time for us to set upon the description of the body, the habitation and fit instrument of all the functions of that divine minde.

The end of the second Booke.

THE

THE THIRD BOOKE TREATING OF THE Anatomy of Mans body.

Following custome and the manner of such as before me have written of Anatomy, will first, (that I may make the mindes of the Readers more attentive and desirous of these studies) declare how necessary it is, and also how profitable, and then shew the order to bee observed in it, before I come to the particular description of mans body.

Furthermore, how Anatomy may bee defined, and the manner of the definition of the parts. For the first, the knowledge of Anatomy seemes in my judgement very necessary

*The necessity
of the know-
ledge of Ana-
tomy.*

to those that desire to excell, or attaine to perfection of Physicke; that is, whereby they may be able to preserve the present health of the body, and the parts thereof, and drive away diseases. For how can either Physicion or Chirurgion preserve health by the use of the like things, which consists in the temperament, conformation, and naturall union of the parts; or expell the disease which hurts those three, by the like use of their contraries, unlesse he shall know the nature and composure of the body, and understand as by the rule of this knowledge, how much it swerves from the nature thereof? Wherefore it is excellently said of *Hippocrates*; that the Physicion called to cure the sicke Patient, ought diligently to consider, whether those things that are in him, or appeare to be in him, be like or unlike, that is, whether the Patient be like himselfe and his owne nature in all his parts and functions, temperature, composure and union; that hee may preserve those which are yet contained in the bounds of nature, and restore those that are gone astray. Which thing *Galen* hath also confirmed, specially where hee saith; hee must well know the nature and structure or composure of the bones, who takes upon him to restore them broken or dislocated to themselves and their proper seates or places. Moreover seeing that healing doth not onely consist in the knowledge of the disease, but as well in prescribing fit medicines and like application of them to the body and the parts thereof, all which by their naturall dissimilitude, doe require unlike medicines, according to *Galen*'s opinion: I prethe tell mee, who can performe this, which is ignorant of the description of the whole and the parts thereof, taught by Anatomie? We may say the like of the Apothecarie, who ignorant of the scituation of the parts in the body, cannot apply Emplaisters, Ointments, Cataplasmes, Fomentations, Epithemes, bagges to the fit places, as to the sutures of the skull, to the Heart, Liver,

*Initio lib. de
Offic. medici.*

Lib. de osibus.

*I. de loc. affe-
ctu, & lib. 3.
Meth.*

Stomacke,

Why when
the liver is hot,
the stomacke
is commonly
cold.

Stomacke, Spleene, Reines, Wombe or Bladder. For example, let us imagine the Liver to be troubled with a hot distemperature, but on the contrary the stomacke with a cold (which commonly happens, seeing the Liver hotter than it ought to be, sends up many vapours to the head; from whence cold humors fall into the stomacke) if hot things to be applied to the stomacke by the Physitions prescription, be by the Apothecarie making no difference, applied both to the stomacke and neighbouring Liver (which may chance if hee be ignorant that the stomacke bends somewhat to the left side under the breast-blade; but the liver so takes up the right side of the body that with a great part thereof, it covers almost all the stomacke) will not be much offend by encreasing the hot distemper of the liver, and not thereby giving ease, or helpe to the disease? Shall not by this his ignorance, the Patient be frustrated of his desire, the Physition of his intent, and the medicine of its effect? By these examples I thinke it most manifest, that the Anatomieall knowledge of the parts of the body is exceeding necessary to all Physitions, Chirurgions, and Apothecaries, who will practise Physicke with any praise to the glory of God, and the benefit and good of man, for whose sake wee have writ these things, and illustrated them by figures, subjecting the parts to the eye, and fitly put them in their proper places,

The know-
ledge of Ana-
tomy, is com-
modious four
manner of
wayes.

But Anatomy is commodious foure manner of wayes; the first is, because thus we are led to the knowledge of God the Creator, as by the effect to the cause; for as we reade in Saint Paul, The invisible things of God are made manifest by the visible. The second is, That by meanes hereof wee know the nature of mans body, and the parts thereof, whereby wee may more easily and certainly judge and determine of sicknesse and health. The third is, that by the knowledge of the body and its parts, and together therewith its affections and diseases, wee may prognosticate what is to come, and foretell the events of diseases. Lastly, the fourth is, that considering the nature of the diseased part, we may fitly prescribe medicines, and apply them in their due places.

There is a
threefold
method.

Now we must declare in what order Anatomie may be fitly delivered; but first we must observe there is a threefold Methode; The first is called of Composition, being very commodious for the teaching of Arts, which Aristotle hath used in his Workes of Logicke, and naturall Philosophy, the order and beginning taken from the least and most simple to the more compound. The second of Division, fit for the inventing or finding out of sciences. Galen hath followed this order in his Bookes of Anatomieall Administrations, and of the use of the parts. The third of Definition, which sheweth the nature and essence of things, as appears by Galen in his Booke *De Arte parva*. And because this order doth also prosecute the divisions, therefore it is commonly accustomed to be comprehended in the compasse of the second. Therefore I will follow this in my Anatomieall Treatise, deviding mans body into its parts, which I will not onely subiect to the eye in the way of knowing them, but also to the minde in the faithfull understanding them. For I will adjoyne those things that are delivered of them by Galen in his Booke of Anatom. Administrations, with those which hee hath taught in his Bookes of the use of the parts. For there hee fitly laies the parts of mans body before our eyes, to the sense. But here he teaches to know them, not to see them; for hee shewes why, and for what use they are made. Having briefly handled these things, wee must declare what Anatomy is; that as Cicero saith out of Platoes *Phaedro*, it may be understood of what we dispute. And because we attaine that by definition (which is a short and plaine speech, consisting of the Genus and difference of the things defined, being the essentiall parts, by which the nature and essence of the thing, is briefly and plainly explained) first we define Anatomy, then presently explaine the particular parts of the definition.

The Authors
intent.

What Anato-
my is.

How a defi-
nition differs
from a des-
cription.

Wherefore Anatomy, (if you have regard to the name) is a perfect and absolute division, or artificiall resolution of mans body into its parts, as well generall as particular, as well compound as simple. Neither may this definition seeme illegitimate, specially amongst Physitions and Chirurgions. For seeing they are Artizans humiliated to the sense, they may use the proper and common qualities of things for their essentiall differences and formes. As on the contrary, Philosophers may refuse all definitions as spurious, which consist not of the next Genus and the most proper, and essentiall

essentiall differences. But seeing that, through the imbecilitie of our understanding, such differences are unknowne to us, in their places we are compelled in defining things, to draw into one many common and proper accidents, to finish that definition which we intend, which for that cause we may more truly call a description, because for the matter and essentiall forme of the thing, it presents us onely the matter adorned with certaine accidents. This appeares by the former definition, in which *Division* and *Resolution* stand for the *Genus*, because they may be parted into divers others, as it were into *species*. That which is added over and besides, stands in place of the difference, because they separate and make different the thing it selfe from all other rash and unartificiall dissections. We must know an artificiall division, is no other than a separation of one part from another, without the hurt of the other, observing the proper circumscription of each of them; which if they perish or be defaced by the division, it cannot be said to be artificiall; and thus much may suffice for the parts of the definition in generall.

For as much as belongs to the explication of each word; we said of *Mans body*, because, as much as lies in us, we take care of, preserve the health, and depell the diseases thereof, by which it may appeare that mans body is the subject of Physicke, not as it is mans, or consists of matter and forme, but as it is partaker of health and sicknesse. The Subject of Physicke.

Wee understand nothing else by a part, according to *Galen*, than some certaine body, which is not wholly disioyned, nor wholly united with other bodies of their kindes; but so that, according to his opinion, the whole being composed therewith, with which in some sort it is united, and in some kinde separated from the same, by their proper circumscription. Furthermore by the *parts in generall*, I understand the head, breast, belly, and their adjuncts. By the particular parts of those, I understand, the simple parts, as the similar, which are nine in number, as a gristle, bone, ligament, membrane, tendon, nerve, veine, arterie, musculous flesh; some adde fibers, fat, marrow, the nailes and haire; other omit them as excrements; but wee must note that such parts are called simple, rather in the judgement of the sense, than of reason. For if any will more diligently consider the nature, they shall finde none absolutely simple, because they are nourished, have life and sense, either manifest or obscure, which happens not without a nerve, veine, and artery. Gal lib. 1. de usu part. lib. 1. Meth.

But if any shall object, that no nerve is communicated to any bone, except the teeth; I will answer, that neverthelesse the bones have sense by the nervous fibers, which are communicated to them by the *Periosteum*, as by whose mediation the *Periosteum* is connect to the bones, as we see it happens to these membranes, which involve the bowels. And the bones, by this benefit of the animall sense expell the noxious and excrementitious humors from themselves into the spaces betweene them and the *Periosteum*, which as indued with a more quick sense, admonisheth us, according to its office and dutie, of that danger which is ready to seaze upon the bones, unless it be prevented. Wherefore wee will conclude according to the truth of the thing, that there is no part in our body simple, but only some are so named and thought, according to the sense; although also otherwise some may be truly named simple, as according to the peculiar and proper flesh of each of their kindes. Those parts are called compound which are made or composed by the mediation, or immediately of these simple, which they terme otherwise organically or instrumentally; as an arme, legge, hand, foote, and others of this kinde. The similar parts are 9.

And here wee must observe, that the parts are called simple and similar, because they cannot be divided into any particles but of the same kinde; but the compound are called dissimilar from the quite contrary reason. They are called instrumentally and organically, because they can performe such actions of themselves, as serves for the preservation of themselves and the whole; as the eye of it selfe, without the assistance of any other part, seeth, and by this faculty defends the whole body, as also it selfe. Wherefore it is called an instrument or organ, but not any particle of it, as the coates, which cannot of it selfe performe that act. Whereby wee must understand, that in each instrumentally part we must diligently observe foure proper parts. One by which the action is properly performed, as the Crystalline humour in the eye, How the bones come to feele.

The compound, or organically parts.

Foure particles to be observed in each organically part.

eye; another without which the action cannot be performed, as the nerve & the other humors of the eye. The third, whereby the action is better and more conveniently done, as the tunics and muscles. The fourth, by which the action is preserved, as the eye-lids and circle of the eye. The same may be said of the hand, which is the proper instrument of holding, for it performs this action; first by the muscle, as the principall part; Secondly, by the ligament, as a part without which such action cannot be performed. Thirdly by the bones and nailes, because by the benefit of these parts, the action is more happily performed. Fourthly, by the veines, arteries and skin, for that by their benifite and use, the rest, and so consequently the action it selfe is preserved.

Four sorts
of instrument
call parts.

Nine things to
be considered
in each part.

Why the three
principall
parts are so
called.

*Lib. de Arte
medica.*

The use and
function of
the parts ser-
ving for gene-
ration.

But we must consider, that the instrumentall parts have a fourefold order. They as said to be of the first order, which are first and immediately composed of the simple, are onely the authors of some one action, of which kinde are the muscles and vessels. They are of the second which consist of these first simple, and others besides, as the fingers. They are counted of the third rancke, which are composed of parts of the second order and some besides, as the hand taken in generall. The fourth order is the most composed, as the whole body, the organ and instrument of the soule. But you must observe, that when we say the muscles and vessels are simple parts, we refer you to the sense and sight, and to the understanding, comparatively to the parts which are more compound; but if any consider their essence and constitution, he shall understand they are truly compound, as we said before. Now it remaines, that wee understand, that in each part, whether simple or compound, nine things are to be considered, as substance, quantitie or magnitude, figure, composition, number, connexion, (by which name, we also understand the originall and insertion) temperature, action, and use; that by the consideration of these things, every one may exercise the art of Physicke, in preserving health, curing diseases, or foreseeing their events and ends.

But also wee must note, that of the organicall parts, there be three, by whose power the body is governed; which for that cause they call regent and principall; because they governe all the rest; they are the liver, heart, and braine. But they are called principall, not onely because they are necessary for life (for the stomacke, winde-pipe, lungs, reines, bladder, and such like parts perhaps are equally as necessary for life) but because from each of these three, some force, power, and facultie, or also matter necessary for the whole body, flow over all the body, when no such thing proceeds from the rest of the parts. For from the liver a matter fit for nourishment, is distributed by the veines through all the body; from the heart the vitall force diffused by the arteries, imparts life to the whole body; from the braine by the nerves a power or facultie is carried through all the parts of the body, which gives them sense and motion.

Galen would have the Testicles to be of this kinde, not for the necessitie of the individuall, or peculiar body, but for the preservation of the *Species* or kind. And moreover in his book *de Semine* comparing the Testicles with the heart, he makes them the more noble by this reason, that by how much it is better to live well and happily, than simply and absolutely to live, by so much the testicles are more excellent than the heart, because with them wee may live well and pleasantly, but with this simply live, as we see by the example of Eunuches, and such as are gelt, by which the Testicles seeme rightly to be accounted amongst the principall parts; for nature seeing it desired, that this its worke should be immortall, for the attaining of that immortality which it intends, frames those parts, like as prudent founders of a Citie, who doe not onely procure to furnish their citie with many inhabitants, so long as they are in building it, but also that it may remaine in the same state and condition for ever, or at least for many ages. And yet notwithstanding of so many cities built in the first memory of man, there remaines none, whose fame and state, together with the builders name is not decayed and perished. But this humane worke of nature, stands yet secure for this many thousand of yeares, and shall endure hereafter, because it hath found a way, by which every one may substitute another in his place before he depart. Hence it is that all creatures have members fit for generation, and pleasures inserted

in those members, by which they might be inticed to mutuall embraces and copulations. But the mind, which hath dominion over those members, hath an incredible desire of propagating the issue, by which also brute beasts incited, desire to propagate their kinds for ever. For seeing that nature understands all these her workes considered particularly by themselves, are fraile and mortall, it hath done what it could to recompence that fatall necessitie of dying, by a perpetuall succession of individuals.

Hitherto we may seeme to have abundantly shewed what necessitie of knowledge in Anatomy belongs to all Artizans in Physicke, and also what order is to be observed in the same. And lastly, how it is defined, and the reason of the parts of the definition. Wherefore it remaines that wee prosecute what wee have taken in hand, which is, that wee shew and declare how to know all and every the parts of mans body, how many, and what they be, and to understand wherefore they be. For although the true knowledge of Anatomy may be perfected by the sight of the eye, and touching and handling each part with the hand, yet nevertheless the labour of describing Anatomy is not unprofitable. For by reading, such as have often exercised themselves in the dissecting of mens bodies may refresh and helpe their memories, and such as have not, may make plaine and easie the way to the understanding of dissections.

CHAP. I.

The Division or partition of Mans body.

REason the partition of mans body can hardly be understood, if the distinction of the proper faculties of the soule be not understood, for whose cause the body enjoyes that forme (which wee see) and devision into divers instruments; Therefore I thought good in few words to touch that distinction of the faculties of the soule, for the better understanding of the partition of the body which wee intend. Wherefore the soule, the perfection of the body, and beginning of all its functions, is commonly distinguished and that in the first and generall division, into three faculties, which are the Animall, vitall, and naturall. But the Animall is divided into the principall, sensitive, and motive; Again, the principall is distinguished into the imaginative, reasonable, and memorative. And the sensitive into Seeing, Hearing, Smelling, Tasting, and Touching. But the motive into progressive and apprehensive. And the vitall is divided into the dilative, and contractive facultie of the heart and arteries, which we know or understand by the pulsificke facultie. But the naturall is parted into the nutritive, auctive, and generative faculties; which three performe their parts by the helpe and ministrie of five other faculties, which are, the Attractive, Retentive, Concoctive, Assimulative, and Expulsive.

What the soule is, and with how many faculties it is endued.

After the selfesame manner, the organ or instrument of the soule, to wit, Mans body, at the first division is distinguished into three parts, which from their office they call Animall, vitall, and naturall. These againe, according to the subdivision of the subalternall faculties, are divided particularly into other parts; so that any one may know the organ of each facultie, by the propertie of the function. For while other Anatomists divide mans body into foure universall and chiefe parts, they distinguish from the three first, those which they call the Extremities; neither doe they reach to what rancke of the three prime parts each extremitie should be reduced. From whence many difficulties happen in reading the writings of Anatomists; for shunning whereof, we will prosecute, as wee have said, that distinction of mans body, which we have touched before.

All the parts of mans body are distinguished into three.

Wherefore, as wee said before, mans body is divided into three principall and generall parts, Animall, Vitall, and Naturall. By the Animall parts, wee understand not onely the parts pertaining to the head, which are bounded with the crowne of the head, the collar-bones, and the first *Vertebra* of the breast, but also the extremities,

What parts are here called Animall.

ties, because they are organs and instruments of the motive facultie; *Hippocrates* seems to have confirmed the same, where hee writes; Those who have a thicke and great head, have also great bones, nerves, and limbs. And in another place hee saith, those who have great heads, and when they stoope shew a long necke, such have all their parts large, but chiefly the animal. Not for that *Hippocrates* would therefore have the head the beginning and cause of the magnitude and greatnesse of the bones, and the rest of the members; but that he might shew the equallity, and private care or government of nature, being most just and exact in the fabricke of mans body, as if she hath well framed the head, it should not be unlike, that shee idly or carelesly neglected the other parts which are lesse seene. I thought good to dilate this passage, least any might abuse that authoritie of *Hippocrates*, and gather from thence, that not onely the bones, membranes, ligaments, gristles, and all the other animall parts, but also the veines and arteries depend on the head as the originall. But if any observe this our distinction of the parts of the body, he will understand wee have a farre other meaning.

What parts
are called vi-
tall.

The devision
of the animall
parts.

The devision
of the vitall
parts.

The devision
of the naturall
parts.

By the vitall parts, we understand onely the heart, arteries, lungs, winde-pipe, and other particles annexed to these. But by the naturall, wee would have all those parts understood which are contained in the whole compasse of the *Peritonaeum* or Rim of the body, and the proccesses of the *Erythroides*, the second coate of the Testicles. For as much as belongs to all the other parts, which we call containing; they must be reckoned in the number of the animall, which notwithstanding, we must thus devide into principall, sensitive, and motive; and againe, each of these in the manner following. For first the principall is devided into the imaginative, which is the first and upper part of the braine, with its two ventricles and other annexed particles; into the reasoning, which is a part of the braine, lying under the former, and as it were the toppe thereof with its third ventricle. Into the memorative, which is the *cerebellum* or afterbraine, with a ventricle hollowed in its substance. Secondly, the sensitive is parted into the visive, which is in the eyes; the auditive, in the eares; the smelling, in the nose; the tasting, in the tongue and palate; the tactive, or touching which is in the body, but most exquisite in the skinne which invests the palmes of the hands. Thirdly, the motive, is devided into the progressive, which intimates the legges, and the comprehensive, which intimates the hands. Lastly, into simply motive, which are three parts, called bellies, for the greatest part terminating and containing; for the vitall, the instrument of the faculty of the heart, and dilatation of the arteries, are the direct or streight fibers, but of the constrictive the transverse; but the three kinds of fibers together, of the pulsifick; or if you please you may devide them into parts serving for respiration, as are the lungs, and weazon, and parts serving for vitall motion, as are the heart and arteries, furnished with these fibers, which we formerly mentioned. The devision of the naturall parts remaines, which is into the nourishing, auctive and generative, which againe are distributed into attractive, universall, and particular; retentive, concoctive, distributive, assimilative, & expulsive. The attractive, as the gullet and upper orifice of the ventricle; the retentive, as the *Pylorus* or lower passage of the stomacke; the concoctive, as the body of the ventricle, or its inner coate; the distributive, as the three small guts; the expulsive, as the three great guts; we may say the same of the liver, for that drawes by the mesaraicke and gate veines, retaines by the narrow orifices of the veines dispersed through the substance thereof; it concocts by its proper flesh; distributes by the hollow veine, expels by the spleene, bladder of the gall and kidneies. We also see the parts in the testicles devided into as many functions; for they draw by the preparing vessels; retaine by the varicous crooked passages; in the same vessels they concoct the seed by the power of their proper substance and facultie; they distribute by the ejaculatorie, at the glandules called *Prostata*, and the hornes of the wombe, supplying the place of prostates; Lastly, they expell or cast forth by the prostates, hornes, and adjoyning parts. For as much as belongs to the particular attraction, retention, concoction, distribution, assimilation of each part, that depends of the particular temper, and as they terme it, occulte proper-tie of each similar and simple part. Neither doe these particular actions differ from the universall, but that the generall are performed by the assistance of the three sorts of

of fibers, but the speciall by the severall occult propertie of their flesh, arising from their temperature, which we may call a specificke propertie. Now in the composition of mans body, nature principally aimes at three things. The first is, to create parts necessary for life, as are the heart, braine, and liver. The second, to bring forth other for the better and more commodious living, as the eyes, nose, eares, armes and hands. The third is, for the propagation and renewing the *species* or kind, as the privie parts, testicles, and wombe. And this is my opinion, of the true distinction of mans body, furnished with so many parts, for the performance of so many faculties; which you, if you please, may approve of and follow. If not, you may follow the common and vulgar, which is, into three bellies, or capacities, the upper, middle, lower (that is, the head, breast and lower belly) and the limbs or joints. In which by the head we doe not understand all the Animall parts, but onely those which are from the crowne of the head to the first *vertebra* of the necke, or to the first of the backe, if according to the opinion of *Galen Lib. de ossibus*, where he makes mention of *Enarthrosis* and *Arthrodia*, we reckon the necke amongst the parts of the head. By the breast, whatsoever is contained from the coller bones to the ends of the true and bastard, or short ribbs, and the midriffe. By the lower belly, the rest of the trunk of the body, from the ends of the ribbs to the share-bones; by the limbs, we understand the armes and legges. We will follow this division in this our Anatomical discourse, because wee cannot follow the former in dissecting the parts of mans body, by reason the animall parts are mutually mixed with the vitall and naturall, and first of the lower belly.

The vulgar
division of
mans body.

Nature would not have this lower belly bony, because the ventricle might bee more easily dilated by meate and drinke, children might grow the better, and the body be more flexible. It is convenient we beginne our Anatomical administration from this, because it is more subject to putrefaction than the rest, both by reason of its cold and moist temperature, as also by reason of the feculent excrements therein contained. Yet before we goe any further, if the Anatomical administration must be performed in publike, the body bring first handsomely placed, and all the instruments necessary for dissection made ready, the belly must be devided into its parts, of which some containe, and other some are contained.

Why the belly
is not bony.

They are called containing, which make all that capacity which is terminated by the *Peritonaeum* or Rim of the belly. The vpper part whereof is bounded by *Galen* within the compasse of the direct muscles, and by a generall name is called *Epigastrium*, or the vpper part of the lower belly. That againe is devided into three parts, that is, into that which is above the navell, and which carries the name of the whole, into that which is about the navell, and is called the umbilicall or middle part; and lastly, into that which is below the navell, called the *Hypogastrium*, or the lower part of the lower belly.

The division
of the lower
belly.

In every of which three parts there be two laterall, or side parts to be considered, as in the *Epigastrium*, the right and left *Hypochondria*, which are bounded above and below, in the compasse of the midriffe, and the short ribbs. In the vmbilicall the two *Lumbares* (some call them *Latera fides*) which on both sides from the lowest parts of the breast, are drawne to the flankes, or hanch-bones; in the *Hypogastrium*, the two *Ilia*, or flankes, bounded with the hanch and share-bones. Neither am I ignorant, the *Ilia* or flankes, which the Greekes call *Λαγῆες* signifie all the emptie parts, from the ends of the ribs, even to the hanch-bones, whereupon they also call them *κεῖραρες* as if you should say, empty spaces, because they are not encompassed with any bone. Yet I thought good that this doctrine of deviding the belly should be more distinct, to call the parts which are on each side the navell *Lumbares*, and those on the lower part of the lower belly *Ilia*, flankes. But we must observe that the Ancients have been so diligent in deciphering the containing parts, that as exactly as might be, they designed the bowells contained in the belly, which being diverse lie in sundrie places; for the greater portion of the liver lies under the right *Hypochondrium*; under the left almost all the ventricle and spleene. Under the *Epigastrium* the lower orifice of the ventricle, and the smaller portion of the liver; In the *Lumbares*, or sides, in the right and upper part the right kidney, in the lower part towards the flankes, the

The *Hypo-*
chondria.

blinde gut: in the middle part thereof the collicke and emptie guts. In the upper part of the left side lies the left kidney, in the middle part, the rest of the emptie and collike guts. Vnder the region of the navell, lies the girdle or upper part of the kall, the collike gut thrusting it selfe also through that way. Vnder the *Ilia* or flanks, the right and left, lie the greater part of the gut Ileon, the hornes of the wombe in women bigge with child, and the spermaticke vessels in men and women. Vnder the *Hypogastrium* in the lower part lies the right, or straight gut, the bladder, wombe, and the rest of the kall.

A most certaine note of the part affected, by the place where the paine is.

If we know, and well understand these things, wee shall more easily discern the parts affected by the place of the paine, and cure it by fit application of remedies, without the hurting of any part. The distinction of such places, and the parts in those places, as seeming most profitable, I have thought good to illustrate by the placing these two following figures, in which thou hast deciphered, not onely the foresaid parts, containing, and contained, but also of the whole body, and many other things which may seeme to conduce to the knowledge of the mentioned parts. The Figures are these.

The Figure shewing the foreparts of the body.

- A The hairy Scalp, cald *τριχωτις*. Z The region of the navill, cald *lepus umbilicus*, or the middle part of the lower belly.
- b the forehead cald *Frontis*. *μετωπον*. A. The navill *umbilicus*. The roote of the belly *δρυπαλ*.
- c the temples cald *τεπορας*, *αροτουροι*. BB. The side, *Latera*, *πλευρα*. and in our Author, *Lumbi seu Lumbaris regio*.
- From b to d The compasse of the face.
- e The greater or inward corner of the eyes, cald *Canthus internus*. C. *Hypogastrium*, the water-courle, *Aquaticulus*, the lower part of the lower beelley, *ινεγυ*.
- f The lesser or externall angle of the eye, cald *Canthus externus*. DD. The flanks called *Ilia* and *κεντρεις*.
- * The lower eyebrow which is immovable, *Palpebra*. E. The Groine called *pubes* or *pecten*, *αλεις* *αλβιν*.
- g The cheek-ball cald *mala*, *μηλα*. FF. The Leske cald *inguen*, where those tumors are cald *Bubones*.
- h The cheek-puf cald *buccae*, *γναθος*. G. the yard with the foreskinne, *penis cum praputio*.
- i The ridge of the nose cald *Nasus externus*, *ριν*. H. the stones or testicles, with the cod or *scrotum*.
- k The nostrills cald *nares*, *μυκητες*. II. the shoulders *humeri*, *επωμιδες*.
- l The outward eare, *auris externa*. KK. the armes *Brachia*, *βραχια*.
- m The mouth made of the two lips, *Os*. L. the bowt of the arme, called *Gibber*, *ανδον*.
- n The chin cald *mentum*, *χιν*. M. the outside of the lower part of the arme cald *cubitus*, *αγκυς*.
- o The necke, *collum*, *αυχην* and *truncus*, and *δρυπαλ*. N. the wrest called *Brachiale*, *κερπος*.
- From o to e the pillar of the necke, *truncus*, and *δρυπαλ*. O. the after-wrest *postbrachiale*, *μετακερπον*.
- pp The hollow of the necke, cald *inguli*, *σφαρδι*. P. the Palme called *Palma* or *volo manus*, *θεναρ*.
- qq The patel bones, *claves*, *κλειδες*. q the backe of the hand *Dorsum manus*, *οπισθεναρ*.
- r The chest *pectus*, *σερρον*. QQ. the fore ann middle part of the thigh, where wee apply cuppingglasses to bring downe womens courles, *μημεν*.
- s The right brest.
- ss The left brest: to this Region we apply cordiall Epithemations moist and drie.
- tt The nipples of the breasts, *Papillae*, *θυλοι*. RR. the knee, *genus*, *γονυ*.
- u The trench of the heart which the Ancients called *καρδια*. The Latines *serobiculus Cordis*. This part is annoited for the mouth of the stomacke.
- From u to E the lower belly, *γαστρ*. SS. the leg, *Tibia*, *Κνήμη*.
- x The *Epigastrium* or upper part of the lower belly. TT. the calfe of the leg *fura*, *γαστρονήμων*.
- yy The *Hypochondria* or *Precordia*. VV. the instep, *tarsus*.
- * The outward Liver-remedies are applied to this place. XX. the top of the foote *Dorsum pedis*, *πυθ* *μοδης*.

YY. the inner Ankles, *σφυρα*. ZZ. the outward ankles. aa the toes of the feete, b the place under the inward ankle, where the veine called *Saphena* is opened.

The Figure of the backe parts of a man.

- A The forepart of the head, *syncephus*, *βρεγμα*.
 B. the top or crowne of the head *vertex*, *κορυφή*.
 C. the hinder-part of the head, *occipus*, *κόλις*
ἐπὶ τῷ.
 From D. to D. the face, *Facies*, *πρόσωπον*.
 * E. the eyebrowes *superctilia*, *ὀφρύς*.
 F. the upper eye-lid, *βλέφαρον*.
 * The tip of the nose cald *globulus nasi*.
 H. the backe part of the necke, cald *cervix*, *ἀντήρ*.
 and the nuke or nape of the necke. There is a
 hollownesse at the top of this *cervix*, where wee
 apply Seaton.
 I. the backe part of the shoulder top, called *ax-*
illa, *ὤμος*.
 KK. the shoulder blades *scapulae*, *ὀμοπλάται*.
 1, 2, 3. On this place wee set cupping glasses,
 4, 5, 6, 7. the backe *dorsum*, *ὠμῶν*.
 8, 9. the ridge, *spina dors*, *ρῆγες*.
 L the arme hole, *ala*, *μαχαλὴ*.
 * the elbow, *Gibber brachij*.
 M M M M. the sides, *Latera*.
 N N the loines *Lumbi*, or the region of the kid-
 nyes, *ὀσφες*.
 O O. the place of the hips, *coxendices*, where we
 apply remedies for the Sciatica.
 P. the place of the holy-bone, or *Os sacrum* where
 we apply remedies in the diseases of the right gut.
 Q. the place of the Rumpe or *Coccyx*.
 R R. the buttocks *Nates*, *κλώες*.
 S S. the backe parts of the thigh, *Femur*.
 T T. the ham, *Poples*, *ἰχρὺς*.
 V V. the calfe of the leg, *sura*.
 X X. the foote or *parvus pes*, *πῶς*.
 Y Y. the utter ancle, *Malleolus externus*.
 Z Z. the heele, *calx* or *calcaneus*, *ἰσχυα*.
 a a the sole of the foote *Planta pedis*, *ἰσχυὸν τῆς πῶδος*.
 b the inside of the lower part of the arme called
Ulna, *ὠλή*.
 c. the outside of the same, *Cubitus*, *πῦξ*.
 dd the wrest, *Carpus*.
 ee the backe part of the hand, *dorsum manus*. g. the
 forefinger *index*, *δείκνυσι*. h. the thumb, *pollex*,
ἀντίχειρ.
 i. the middle finger, *medius*, *ὠστ*.
 k the ring-finger *Annularis*, *medicus*, *ἰσχυρὸς*.
 l. the little finger, *Auricularis*, *minimus*, *ὠστὴς*.

CHAP. II

Of the containing parts of the Epigastrium, and the preparation
to Anatomical administration.

He containing parts of the *Epigastrium* are the *Epidermis* or thinne outward
 skinne, the true skinne, the fleshie or fatty Pannicle, the eight muscles of
 the *Epigastrium* with their common coate, the Rim of the belly, the five
 vertebra's of the loines, all the holy-bone, the hanch-bone, share-bone,
 the white line, and midriffe. Of these parts some are common to the whole body,
 as the three first; the other proper to the parts contained in the *Epigastrium* taken in
 generall. Which that you may see in their order, first you must cut round about the
 navell, to the upper superficies of the muscles, that so wee may keepe it, till such
 time, as occasion shall offer it self, to shew the vmbilicall vessels lying in that place,
 which are one veine, two arteries, & the *urachus* (if it be there.) Which being done,
 you must draw a straight line from the chest, over the breast-blade, even to the share-
 bone, which may divide the common containing parts, even to the white line.

The contain-
 ing parts of
 the lower belly

Then presently it will be convenient to draw two other lines across, or overthwart, of the like depth on each hand, from the circumference of the navell, even to the sides, that so on each part wee may draw the skinne more commodiously from the parts lying vnder it; the sight of which otherwise it would hinder. These things being done, the skinne must bee devided from the parts lying under it from the designed circumference left about the navell. Wee must teach how the skinne is twofold, the true and false, and render a reason of the name, which we will every where doe, as farre as the thing will suffer, and it shall lie in our power. And in doing or examining these things, it will be convenient diligently to inquire into the nine things mentioned in the preface. Wee will beginne with the skinne, because that part is first obvious to our senses.

CHAP. III.

Of the utmost skinne or Cuticle.

The skinne
twofold.
From what
parts the skin
cannot be se-
parated.

He skinne being the first part, and spread over all the body, is twofold, that is, the true, and bastard skinne. The true is called by the Greekes *Derma*, which may almost every where be pulled from the parts lying under it, which it invests; except in the face, eares, the palmes of the hands, soles of the feete, fingers, and privities, where it stickes so close that it cannot be separated.

The matter of
the Cuticle.

The bastard (which first of all wee will declare, because it first presents it selfe to our sight) is by the Greekes called *Epidermis*; because it covers the true skinne, they terme it commonly the Cuticle. The substance of it is excrementitious, and as it were a certaine drie flouring, or production of the true skinne. That it drawes not its substance from the seede is apparent by this, that as it is easily lost, so it is easily repaired, which happens not in parts truly spermaticall. This utmost thinne skinne, or cuticle, may two manner of wayes be made apparent by it selfe, and separated from the other, as by burning with fire, or ardent heate of the Sunne (in some delicate bodies, and such as are not accustomed to be conversant in Sun-shine.) The quantitie in thicknesse is very small; but the extent is most large, because it covers all the skinne; the figure of it is round, and long, like those parts which it invests. The compofure of it is obscure; yet because this Cuticle is the excrement of the true skinne, wee say it hath its matter from the excrementitious superfluitie of the nerves, veines, arteries, and substance of the true skinne.

The quantitie.

The figure.
The compo-
sure.

The number.

The tempe-
ratur.

The use

Why the cuti-
cle cannot be
restored in
scars.

It is in number one, like as the true skinne which it outwardly covers, that it might be a *medium* betweene the object, and fixed facultie of touching, diffused over all the true skinne which every where lies under it. For the temperature, by the common consent of Physitions, it is in the midst of all excesse; for that seeing it is the *medium* betweene the object and facultie, if it should be hotter, colder, moister, or drier, it would deceive the facultie by exhibiting all objects, not as they are of themselves, but as it should be; no otherwise than as to such as looke through red or greene spectacles, all things appeare red, or greene. Wherefore for this reason it was convenient the cuticle should be void of all sense. It hath no action in the body, but it hath use, for it preserves and beautifies the true skin; for it seemes to be given by the singular indulgence of nature, to be a muniment and ornament, to the true skinne. This providence of nature, the industrie of some Artizans (or rather *Curtizans*) doth imitate, who for to seeme more beautifull, doe smooth and polish it. By this you may understand; that not all the parts of the body have action, yet have they their use, because, according to *Aristotles* opinion; Nature hath made nothing in vaine. Also you must note that this thinne skinne, or cuticle being lost, may everie where be regenerated, unlesse in the place which is covered with a scarre. For here the true skinne being deficient, both the matter and former facultie of the cuticle is wanting.

CHAP. III.

Of the true skinne.

He true skinne called by the Greekes *Derma*, is of a spermaticke substance, wherefore being once lost, it cannot be restored as formerly it was. For in place thereof comes a scarre, which is nothing else but flesh dried beyond measure. It is of sufficient thicknesse, as appeares by the separating from the flesh.

The substance
Magnitude.

But for the extent thereof it encompasses the whole body, if you except the eyes, eares, nose, privities, fundament, mouth, the ends of the fingers where the nailes grow, that is, all the parts by which any excrements are evacuated. The figure of it is like the cuticle round and long, with its productions, with which it covers the extremities of the parts.

Figure.

It is composed of nerves, veines, arteries, and of a proper flesh and substance of its kinde, which wee have said to bee spermatickall, which ariseth from the proceffe of the secundine, which leade the spermaticke vessels even to the navell, in which place each of them into the parts appointed by nature, send forth such vessels, as are spread abroad and diffused from the generation of the skinne. Which also the similitude of them both, that is, the skinne and membrane *Chorion* do argue. For as the *Chorion* is double, without sense, encompassing the whole infant, lightly fastened to the first coate which is called *Ammios*; so the skinne is double, and of it selfe insensible (for otherwise the nerves were added in vaine from the parts lying under it) ingirting the whole body, lightly cleaving to the fleshie Pannicle. But if any object that the Cuticle is no part of the true skinne, seeing it is wholly different from it, and easily to be separated from it, and wholly void of sense: I will answer, these arguments doe not prevaile. For that the true skinne is more crasse, thicke, sensible, vivide, and fleshie, is not of it selfe, being rather by the assistance and admixture of the parts, which derived from the three principall it receives into its proper substance; which happens not in the cuticle. Neither if it should happen would it be better for it, but verily exceeding ill for us, because so our life should lie fit and open to receive a thousand externall injuries, which encompassse us on every side, as the violent and contrary acceffe of the foure first qualities.

Composure.

The skinne of
it selfe is void
of sense.

There is only one skin, as that which should cover but one body, the which it every where doth, except in those places I formerly mentioned. It hath connexion with the parts lying under it by the nerves, veines, and arteries, with those subja-cent parts put forth into the skinne investing them, that there may be a certaine communion of all the parts of the body amongst themselves.

The number.
Connexion.

It is cold and drie in its proper temper in respect of its proper flesh and substance, for it is a spermatickall part. Yet if any consider the sinewes, veines, arteries, and fleshie threds which are mixed in its body, it will seeme temperate, and placed as it were in the midst of contrarie qualities, as which hath growne up from the like portion of hote, cold, moist, and drie bodies. The vse of the skinne is to keepe safe and sound the continuitie of the whole body, and all the parts thereof, from the violent assault of all externall dangers, for which cause it is every where indewed with sense, in some parts more exact, in others more dull, according to the dignitie and necessitie of the parts which it ingirts, that they might all be admonished of their safetie and preservation. Lastly, it is penetrated with many pores, as breathing places, as we may see by the flowing out of sweate, that so the arteries in their *diastole* might draw the encompassing aire into the body, for the tempering and nourishing of the fixed inbred heate, and in the *Systole* expell the fuliginous excrement, which in Winter suppresseth by the cold aire encompassing us, makes the skinne blacke and rough. Wee have an argument and example of breathing through these, by drawing the aire in by transpiration, in women troubled with the mother, who without respiration live onely for some pretty space by transpiration.

The reason
why the skin
is blacker and
rougher in
Winter.

CHAP. V.

Of the fleshie Pannicle.

After the true skiane, followes the membrane, which Anatomists call the fleshy Pannicle, whose nature that we may more easily prosecute and declare, we must first shew what a membrane is, and how many wayes the word is taken. Then wherefore it hath the name of the fleshie Pannicle. A membrane therefore is a simple part, broade and thin, yet strong and dense, white and nervous, and the which may easily, without any great danger be extended and contracted. Sometimes it is called a coate, which is, when it covers and defends some part. This is called the fleshie Pannicle; because in some parts it degenerates into flesh, and becomes musculous, as in a man from the coller bones, to the haire of the head, in which part it is therefore called the broad muscle, where as in other places it is a simple membrane, here and there intangled with the fat lying under it, from whence it may seeme to take or borrow the name of the fatty Pannicle. But in beasts (whence it tooke that name, because in those a fleshie substance maketh a great part of this Pannicle) it appeares manifestly fleshie and musculous over all the body, as you may see in Horses, and Oxen; that by that meanes being moveable, they may drive and shake off their flies, and other troublesome things, by their shaking and contracting their backs. These things considered, we say the fleshie Pannicle in its proper body, is of a nervous or membranous substance, as that which hath its originall from the coate *Amnios*, (which is next to the infant) dilated neare to the navell and stretched forth for the generation of this Pannicle; in which thing I thinke good to note, that as the membranes *Chorion* and *Amnios* mutually interwoven with small nervous fibers, encompasse and invest the child, as long as it is contained in the wombe; so the skinne and fleshie Pannicle knit together by such like bands, engirt the whole body.

What a membrane is.

Why it is sometimes called a coate, sometimes the fleshie and fatty Pannicle.

Why beasts have this pannicle wholly, fleshie or musculous.

The substance

The magnitude and figure.

Number. Composition.

Therefore the fleshie Pannicle is equall in magnitude and like in figure to the true skinne, but that it lies under it, and is contained in it, in some places mixt with the fat, in others encreased by the flesh interwoven with it, and in other some is onely a simple membrane.

The composition of it is such, as the sight of it presents to our eye, that is, of veines, arteries, nerves, and the proper flesh, some whites mixed and interlaced with fat, and sometimes with musculous flesh. It is but one, by reason of the use wee shall presently shew; It is situated betweene the skinne and fat, or common coate of the muscles, annexed to these and the other parts lying under it, by the veines, nerves, and arteries ascending from these inward parts, and implanting themselves into the substance thereof, and then into the true skinne.

The temperature. The use.

The temperature thereof is diverse, according to the varietie of the parts interwoven with it. The use of it is, to leade, direct, and strengthen in their passage, the vessels which are disseminated into the true skinne, and the whole superficies of the body. But in beasts it hath another commoditie, that is, it gives a shaking or trembling motion to their skinne and backe, for that cause we formerly touched.

CHAP. VI.

Of the Fat.

The fat comming neare the condition of an excrement, rather than of a part (as we said, when we treated of the simular parts) is of an oily substance, bred of the aiery and vaporious portion of the blood, which sweating through the pores of the coates, or mouthes of the vessels, becomes concreete about the membranes, and nerves, and cold bodies, and turnes into fat by the coldnesse of the place. Whereby we may know that cold, or a more remisse heate, is the efficient cause of fat, which is manifest by contemplation not onely of creatures of diverse kindes, but also by those of the same species and sexe, if so be that the one be colder than the other.

The fat is rather an excrement than a part. The substance

The efficient cause of fat.

By

By which we may understand that the fat is the more or lesse in quantity according to the different temper of the whole body, and of its particular parts; for its composition, it consists of that portion of the blood which we formerly mentioned, intermixt with certaine membranes, nervous fibers, veines and arteryes. The greatest part of it lyes betweene the fleshy pannicle and the common coate of the Muscles, * Otherwise it is diffused over all the body, in some places more, in some lesse, yet it is alwaies about the nervous bodyes, to which it delights to cleave. Most Anatomists enquire whether the fat lye above or beneath the fleshy pannicle. But methinks this question is both impertinent and idle; being we often see the fat to be on both sides. It is of a middle temper betweene heat and cold, being it ariseth of the more aery portion of the blood; although it may seeme cold in respect of the efficient cause, that is, of cold by which it concreats. For the rest, moisture is predominant in the fat. The use therof is, to moisten the parts which may become dry by long fasting, vehement exercise or immoderate heat, and besides to give heat, or keep the parts warme. Although it doe this last rather by accident, than of its owne nature, as heated by exercise, or by some such other chance; it heats the adjacent parts, or may therefore be thought to heat them, because it hinders the dissipation of the native and internall heat; like as cold heats in winter, whereby the bellyes are at that time the hotter. I know some learned Physicians of our time stiffly maintained, that the fat was hot, neither did they acknowledge any other efficient cause thereof, than temperate heat and not cold. But I thinke it best to leave the more subtile agitation of these questions to naturall Philosophers. But we must note, that at the joints which are more usually moved, there is another sort of fat, farre more solid and hard, than that which we formerly mentioned, often found mixed with a viscid and tough humor like the whites of Eggs, that so it might be sufficient for a longer time to moisten these parts, subject to be hurt by drynesse, and make them slippery & so fitter for motion, in imitation whereof they usually grease hard bodyes, which must be in frequent motion, as coach wheelles and axeltrees. And there is another kind of fat, which is called *Serum*, seame, in one thing differing from the ordinary fat, that is much dryer; the moister and softer portion of the fat being dissipated by the raging heat of the place. For it is found principally about the midriffe, where there are many windings of arteryes and veines, and it is also about the reines, Loines, and *basis* of the heart. The fat is wasted by long fasting; is dried and hardened by vehement exercise and immoderate heate. Hence it is that it is much more compact in the palmes of the hands, and soles of the feet, about the eyes and heart, so that it resembles the flesh in densitie and hardnesse; because by the continuall motion and strong heat of these parts, the thinner portion being dissipated & diffused, the more Grosse & terrestriall remaine.

The quantity.

The composition.

The site.

I was present at the opening a body, Feb:

1630. in which the fat, in the lower part of the lower belly

was in thickness above 8,

inches, upon the breast betweene 4 and 5

inches: which I thought good to remember

in this place both for the rarity of the thing, as also

because it was increased by report, and the place mistaken

some saying the *Omentum* or *Call* was so

thick, which was false, for it did not much

exceed the quantity of that part, in other fat men.

The Temper. The use.

The solidier fat, or seame.

In what parts and for what cause the fat is more dense.

CHAP. VII.

Of the common coate of the Muscles.

NExt under the fat, appeares a certaine coate, spread over all the Muscles, and called the common coate of the Muscles, it is of a nervous substance; as all other membranes are. The quantity and breadth thereof is bounded by the quantity of the Muscles which it involves, and fits it selfe to, as that which encompasses the Muscles of the *Epigastrium*, is of equall largnesse with the same Muscles. The figure of it is round. It is composed of veines, nerves, arteryes and its peculiar flesh consisting of three sorts of fibers; the beginning of it is from the *Periostium*, in that part where the bones give ligaments to the Muscles; or according to the opinion of others, of the nervous and ligamentous fibers of the Muscles, which rising up and diffused over the fleshy superficies thereof, are united for the generation of this coate. But this membrane arising from the *Periostium* (as every membrane which is below the head takes its originall from the *Periostium* either primarily, by the interposition of no *Medium*, or secondarily) is stretched over the Muscles by their tendons. But if any object, that this membrane pluckt from the belly of the Muscle, may seeme

The substance

The quantity

The Composition.

The Original

to end in a ligament. I will answer, that it is the condition of every nervous part, so to binde or fasten it selfe to another part of his owne kinde as to a stay, so that it can scarce be pluckt from thence. We see the prooffe hereof, in the *Peritoneum* or *Rim* in the *Epigastrium* or lower part of the lower belly. That which covers the Muscles of the *Epigastrium* is but one, unlesse you had rather part it in two, the right and the left distinguished by the interposition of the *Linea Alba*, or white Line. It is situate betwixt the fat and Muscles; for it is fastened above and below to these parts with fibers, which in smallnesse and fitnessse exceed the Spiders web. But by its vessells, it participates with the three principall parts, and is of a cold and dry temper. The use of it is, to containe the Muscles in their naturall vnion, and to keepe them as much as in it lyes, from putrification, which may happen to them from *pus* or matter, which is often cast forth of the simular parts into the empty spaces and distances of the Muscles. Wherefore going about to separate the fat of the *Epigastrium* (where thou must begin the dissection of mans body) you must have a care, that you hurt it not with your knife, but that, before you touch the Muscles, see you artificially take it away, that you may the more easily separate the Muscles lying under it, distinguished by a manifest space at the white Line, which is made by the meeting together of the proper coates of all those muscles.

CHAP. VIII.

What a Muscle is, and how many differences there be thereof.

What a Muscle is,

How the circular motion is performed,

From whence the differences of muscles are drawne.

Differences of muscles from their substance.

Differences of Muscles from their original,

 Muscle is the instrument of voluntary motion; and simple voluntary motion is performed six manner of wayes, upwards, downewards, forwards, backwards, to the right hand and to the left; but the compound one way, which is circularly, the which is performed by the continuall succession of the motion of the Muscles ingirting the part. Such a Motion Falconers use when they stretch forth their hand and Lure their Hauke. We have some parts, which have motion without a Muscle; but that motion is not voluntary; such parts be the heart, stomacke, gutts, both the bladders (that is, that of the Gall and that of the urine) and diverse other which have the motions of attraction, expulsion and retention, by the meanes of the three sorts of fibers; for they draw by the right, expell by the transverse, and retaine by the oblique. The differences of Muscles which are many and diverse, are taken from their substance, originall, insertion into the part which they move, forme or figure, holes or openings, magnitude, colour, site, kind of fibers, their conjugation or connexion, heads, bellies, tendons, opposition in action and office. Some in substance are nervous, venous, arterious, because they have manifest nerves, veines and arteryes, as the Midriffe, the Intercoastall and Epigastricke Muscles and many more, and that for their difference from other Muscles, into which neither nerve nor veine, or Arteryes are manifestly inserted, although secretly they admit them all for sense and motion, life and nourishment, such are the Muscles of the wrist, the wormy muscles of the hands and feet; for if there be any nerves observed in them, they are very small. Some had rather make the difference of Muscles thus, that some of them are fleshy, some nervous, others membranous. From their Originall, some arise from the bones, as these which move the hands, armes and Leggs; others from gristles, as the Muscles of the throat; others from membranes which invest the tendons, as the wormy Muscles of the hands and feet; others from ligaments as the Extenders of the fingers; others from other muscles, as the two lower Muscles of the yard which proceed from the Sphincter Muscle of the fundament. Others have no originall, as the membrane which we call the fleshy pannicle assumes flesh in certaine places, and degenerates into a Muscle; such are the *Cremaster* or hanging Muscles of the testicles, the large Muscles of the face, and if you please the Midriffe, as that which is composed of two coates, the one in compassing the ribbs and the *Peritoneum*, hath flesh in the midst betweene the two membranes. And moreover some Muscles have their originall from one onely bone, as these which bend and extend the

the Cubite, others arise of many bones as the oblique descending, the Dorsall and many Muscles of the necke, with arise together from many spondyls and sides of spondyls. There be others according to the opinion of some men, both from the bones and gristles of the *Pubis* at the right or direct Muscles of the *Epigastrum*, yet by their favour I thinke otherwise. Because by the Anatomical and received axiome, A Muscle is there thought to take his beginnings from whence he receives a nerve; but these Muscles take a nerve from the intercostall muscles, wherefore their originall ought to be referred to the sides of the breast-blades, as shall be shewed in due place. From their insertion arise these differences, some are inserted into a bone, as those which move the head, Armes and Legs; others into a gristle, as those of the Throate, eyelids, nose and the oblique ascendant muscles of the *Epigastrum*; some into a bone and gristle both, as the right muscles of the *Epigastrum* and the Midriffe; some into the skin, as the muscles of the lips; others into the Coates as the muscles of the eyes; others into Ligaments, as the muscles of the yeard. But these differences following may be drawne both from their insertion and originall. For some muscles arising from many parts, are inserted into some one part, as divers of these which move the arme, and the shoulder, which arising from many spondiles are inserted into the bone of the shoulder and the shoulder blade. Others arise from one part, and insert themselves into more, as those which arise from the bottome of the shoulder blades, are extended and inserted into some eight or nine of the upper ribbs, to helpe respiration; and the benders and extenders of the fingers and toes; Others arising from many bones are inserted into as many, as some of those which serve for respiration, to wit those which we call the hinder Saw-muscles and the *Semispinatus*, which sends a tendon into all the ribbs. Others have their originall from many bones, and end in gristles of the seven ribbs, as those two which lye under the *Sternon*. Moreover also these differences of muscles may be drawne from the originall and insertion, that some proceed from bones and are inserted into the next bone, to helpe and strengthen the motion thereof, as the three muscles of the Hip; others arise from an upper bone & are not inserted into the next, but into some other, as the long muscles. Some are named from the part they move, as the temporall muscles because they move the temples; others from their office, as the grinding muscles, because they move the skin as a mill, to grinde asunder the meale. From their forme or figure, because some are like Mice, other like Lizards which have their Leggs cut off, for that they imitate in their belly, body or tendon, the belly or taile of such creatures, & from whence the names of *Musculus* and *Lacertus* are derived. Such are those which bend the wrest, and which are fastened to the bone of the Leg, & which extend the foot; Others are triangular, as that which lifts up the arme, called *Epomis* or *Deltoides*, and that which drawes the arme to the breast, called the Pectorall muscle. Others quadrangular as the Rhomboides, or Lozenge muscle of the shoulder blade and the two hindesum-muscles serving for respiration, and two of the wrests which turne down the hand; Others consist of more than foure angles, as the oblique descending, and that muscle with joynes it selfe to it from the shoulder blade; others are round and broad, as the Midriffe, others circular as the *Sphincter* muscle of the fundament and bladder; others are of a pyramidall figure, as the seaventh muscle of the eye, which compasses the opticke nerve in beasts but not in men. Others have a semicirculer forme, as that which shuts up the eye, seated at the lesser corner thereof. Others resemble a Monks cowle, or hood, as the *Trapezius* of the shoulder blade. Besides others at their first originall are narrow, but broad at their insertion, as the Saw-muscle of the shoulder and the transverse of the *Epigastrum*; others are quite contrary, as the three Muscles of the Hippe; others keepe an equall breadth or bignesse in all places, as the intercostall muscles and these of the wrest; others are long and slender, as the long muscle of the thigh; others are long and broad, as the oblique descending muscles of the *Epigastrum*; others are directly contrary, as the Intercostall, which are very narrow. From their perforations, for some are perforated, as the Midriffe which hath three holes, as also the oblique and transverse of the *Epigastrum*, that so they may give passage forth to the preparing spermaticke vessells, and to the ejaculatory vessells, the Coate *Erythroides* associating and strengthening them; others are not perforated. From their magnitude

Where a
muscle hath
its originall.

Differences of
muscles from
their insertion

Differences of
muscles taken
from their
figure.

Differences
from their
perforations.

From their
magnitude,
for

From their
Colour,

for some are most large, as the two muscles of the Hipp, others very small, as the eight small muscles of the necke, and the proper muscles of the Throtle, and the wormy muscles. Others are of an indifferent magnitude. From their colour, for some are white and red, as the Temporall muscles, which have Tendons comming from the midst of their belly; others are livide, as the three greater muscles of the calfe of the leg, which colour they have by the admixtion of the white, or tendinous nervy coate with the red flesh, for this coat by its thicknesse darkning the colour of the flesh, so that it cannot shew its rednesse and fresh colour, makes it seeme of that livide colour. From their scituation, for some are superficiali, as those which appeare under the skin and fat; others deepe in and hid, as the smooth and foure twin muscles; some are stretched out and as it were spread over in a streight and plaine passage, as the muscles of the thigh which move the legge, except the Ham-muscle; others oblique, as those of the *Epigastrium*; other some transverse, as the transverse of the *Epigastrium*, where you must observe, that although all the fibers of the muscles are direct, yet we call them oblique, and transverse by comparing them to the right muscles, as which by the concourse of the fibers make a streight or acute angle.

From their
Site,

From their
fibers,

From the sorts of fibers; for some have one kinde of fiber; yet the greatest part enjoy two sorts running so up and downe, that they either are crossed like the letter X, as happens in the pectorall and grinding muscles; or else doe not concur, as in the Trapezij. Others have three sorts of fibers, as the broad muscle of the face.

From their
connexion,

From their coherence and connexion, or their texture of nervous fibers; for some have fibers somewhat more distant and remote immediately at their originall, than in other places, as you may see in the muscles of the buttocks; Others in their midst and belly, which by reason thereof in such muscles is more big or tumid, their head and taile being slender, as happens in most of the muscles of the arme and leg, in which the dense masse of flesh interwoven with fibers, disioynes the fibers in so great a distance; in othersome the fibers are more distant in the taile, as in the greater Saw-muscle arising from the bottome of the shoulder blade; in others they are equally distant through the whole muscle, as in the muscles of the wrest and betweene the ribbs.

From their
head,

From their head; for in some it is fleshy interwoven with few fibers, as in the muscles of the buttocks; in others it is wholly nervous, as in the most-broad-muscle common to the arme and shoulder blade, and in the three muscles of the thigh proceeding from the tuberosity of the hucle bone; in some it is nervous and fleshy as in the internall and externall muscle of the arme. Besides some have one head, others two, as the bender of the elbow and the externall of the legge, others three as the Threeheaded muscle of the thigh. But wee must note that the word nerve or sinew is here taken in a large signification, for a ligament, nerve and tendon; as *Galen* saith (*Lib. de Ossibus*) and moreover we must observe, that the head of a muscle, is one while above, another while below, otherwhiles in the midst as in the Midriffe, as you may know by the insertion of the Nerve, because it enters the muscle by its head.

From their
belly,

From their belly also, there be some differences of muscles taken; for some have their belly immediately at their beginning, as the muscles of the buttocks, others at their insertion, as the Midriffe. Others just at their head, as those which put forth the Calfe of the leg; in others it is somewhat further off, as in those which draw backe the arme, and which bend the legge; in others the belly extends even from the head to the taile, as in the intercostall muscles and these of the wrest; in others it is produced even to their insertion, as in those of the palmes of the hands and soles of the feet; some have a double belly, distinguished by a nervous substance; as those which open the mouth, and those which arise from the roote of the lower proësse of the shoulder blade.

From their
Tendons,

Moreover the differences of muscles are drawne also from the Tendons, for some have none, at least which are manifest, as the muscles of the lips and the sphincter muscles, the intercostall and those of the wrest; others have them in part, and want them in part, as the Midriffe; for the Midriffe wants a Tendon at the ends of the shorter ribs, but hath two at the first *Vertebra* of the Loines in which it is terminated;

Others

Others have a Tendon indeede. But some of these move with the bone, some not, as the muscles of the eyes, and besides, some of these have broad and membranous tendons, as the muscles of the eyes and *Epigastrium*, except the right muscles; in others they are thicke and round, as in the benders of the fingers; in others they are lesse round, but more broad than thicke, such is the Tendon arising from the twin muscles and *Soleus* of the legge: others have thort Tendons, as the muscles which turne downe the hand; other some long, as those of the palmes of the hands and soles of the feet; besides others produce Tendons, from the end of their belly which Tendons are manifest, others from the midst, as the Temporall muscles.

Besides also others diffuse many tendons from their belly, as in the hands the benders of the fingers, and the extenders of the feet. Other some put forth but one, which sometimes is devided into many, as those which bend the third articulation of the foot; other while many muscles by their meeting together make one Tendon, as the three muscles of the Caste of the leg, and those which bend the cubit and leg. All tendons have their originall, when the nerves and ligaments disperfed through the fleshy substance of a muscle, are by litle and litle drawne and meet together, untill at last carried to the joynt they are there fastened for the fit bending and extension thereof. From the contrariety of their Actions, for some parts have contrary muscles, benders and extenders; Other parts have none, for the Cods and fundament have onely lifters up. From their function, for some are made for direct morions, as those which extend the fingers and toes; others for oblique, as the *Supinators* of the hand and the *Pronators*; others performe both, as the pectorall muscle, which moves, the Arme obliquely upward and downeward, as the upper and lower fibers are contracted; and also out right, if all the fibers be contracted together, which also happens to the *Deltoides* and *Trapezius*. I have thought it good to handle particularly these differences of muscles, because that by understanding them the prognosticke will be more certaine; and also the application of remedies to each part; and if any occasion be either to make incision, or suture, we may be more certaine, whether the part affected be more, or lesse nervous.

From their
Action.

From their
function.

CHAP. IX.

Of the parts of a Muscle.

HAVING declared the nature and differences of a muscle, we must note that some of the parts thereof are compound, or universall, others simple or particular. The compound are the head, Belly and taile. The simple are ligaments, a nerve, flesh, a veine, artery and coate. For the compound parts, by the head we understand the beginning and originall of a muscle, which is one while ligamentous and nervous, otherwhiles also fleshy. By the belly, that portion which is absolutely fleshy; But by the taile, we understand a Tendon consisting partly of a nerve, partly of a ligament promiscuously comming forth from the belly of the muscle. For as much as belongs to the simple, which are fixe in number, three are called proper, and three common. The proper are a Ligament from a bone, a nerve proceeding from the Braine, or spinall marrow, and flesh compact by the concretion of blood. The Common are, a veine from the Liver or trunk arising from thence; an artery proceeding from the Heart, a Coate produced by the nervous & ligamentous fibers spreading over the superficies of the muscle. But for the simple use of all such parts, the nerve is as it were the principall part of a muscle, which gives it sense and motion, the Ligament gives strength, the flesh contains the nervous and ligamentous fibers of the muscle and strengthens it filling up all the void spaces, and also it preserves the native humidity of these parts and cherisheth the heat implanted in them; and to conclude, defends it from all externall injuries; for like a fan it opposeth it selfe against the heat of the Sunne; and is as a garment against the cold; and as a cushion in all falls and bruises, and as a buckler or defence against wounding weapons. The veine nourishes the muscle, the arterie gives it life, the coat preserves the

The compound & simple parts of a muscle.

What use each simple part hath in a muscle.

the harmony of all the parts thereof, lest they should be any wayes disioyned or corrupted by purulent abscesses breaking into the empty or void spaces of the muscles, as we see it happens in a Gangrene, where the corruption hath invaded this membrane by the breaking out of the more acride matter or filth.

CHAP. X.

A more particular inquisition into each part of a muscle.

Ligamentous
fibers.

By what
power the
simular parts
principally
draw, or
attract.
What and of
how many
sorts the flesh
is.

Aving gone thus farre, it remaines, that we more particularly inquire into each part of a muscle, that (if it be possible,) nothing may be wanting to this discourse. Wherefore a Ligament properly so called, is a simple part of mans body, next of a bone and gristle, the most terrestriall, dry, hard, cold, white, taking its originall immediatly, or by the interposition of some Medium from the Bones, or Gristles (from whence also the Muscles have their beginning) wherby it comes to passe that a ligament is void of sense, unlesse it receive a nerve from some other place; (For so the Ligaments which compose & strengthen the Tongue and yeard, are partakers of sense) and it inserts it self into the bone and gristle that so it may bind them together, and strengthen and beautifie the whole joynt or connexion; (for these three be the principal uses of a Ligament) then diffusing it self into the membranes and muscles to strengthen those parts. A nerve to speake properly, is also a simple parte of our body, bred and nourished by a grosse and Phlegmaticke humor, such as the braine, the originall of all the nerves, and also the Spinall marrow endowed with the faculty of feeling and oftentimes also of moving. For there be divers parts of the body which have nerves, yet are destitute of all voluntary motion, having the sense onely of feeling, as the membranes, veines, arteries, guts and all the entrailes. A nerve is covered with a double cover from the two membranes of the braine, and besides also with a third proceeding from the ligaments which fasten the hinder part of the head to the *Vertebra's*, or else from the *Pericranium*. Wee understand no other things by the fibers of a nerve, or of a Ligament, than long and slender threds, white, solid, cold, strong more or lesse according to the quantity of the substance, which is partly nervous and sensible, partly Ligamentous and insensible. You must imagine the same of the fleshy fibers in their kind; but of these threds some are straight for attraction, others oblique for retention of that which is convenient for the creature, and lastly some transverse for the expulsion of which is unprofitable. But when these transverse threds are extended in length, they are lessened in bredth; but when they are directly contracted, they are shortened in length. But when they are extended all together as it were with an unanimous consent, the whole member is wrinkled as contracted into it selfe, as on the contrary it is extended when they are relaxed. Some of these are bestowed upon the animall parts, to performe voluntary motions; others upon the vitall to performe the agitation of the Heart and Arteries; others upon the naturall for attraction, retention and expulsion. Yet we must observe, that the attraction of no simular part is performed by the helpe of the foresaid fibers or threds, but rather by the heat implanted in them, or by the shunning of Emptinesse, or the familiarity of the substance. The flesh also is a simple and soft part composed of the purer portion of the blood insinuating it selfe into the spaces betweene the fibers, so to invest them for the uses formerly mentioned. This is as it were a certaine wall and Bulwarke against the injuries of heat and cold, against all falls and bruises, as it were a certaine soft pillow or cushion yeelding to any violent impressiō. There be three sorts of flesh; one more ruddy, as the musculous flesh of perfect creatures and such as have blood; for the flesh of all tender and young things having blood, as Calves, and also of all sorts of fish, is whitish, by reason of the too much humidity of the blood. The second kinde is more pallid, even in perfect creatures having blood, such is the flesh of the heart, stomacke, weasond, guts, bladder, wombe. The third is belonging to the entrailes, or the proper substance of each entrail, as that which remaines of the Liver (the veines, arteries and coate being taken away) of the bladder

bladder of the Gall, braine, kidneys, milt. Some adde a fourth sort of flesh which is spongy, and that they say is proper to the tongue alone.

A veine is the vessel, pipe or channel of the blood, or bloody matter; it hath a spermaticke substance, consists of one coate composed of 3 sorts of fibers. What a veine is.

An Artery is also the receptacle of blood but that spirituous and yellowish, consisting in like manner of a spermaticke substance; But it hath two coats, with three sorts of fibers, the utmost whereof is most thin, consisting of right fibers and some oblique: But the inner is five times more thicke and denser than the utmost, interwoven with transverse fibers; and it doth not onely containe blood and spirit, but also a serous humor, which wee may believe because there bee two emulgent Arteryes, as well as veines. What an artery is.

But the inner coat of an Artery is therefore more thick, because it may containe blood which is more hot, subtle and spirituous; for the spirit, seeing it is naturally more thin and light and in perpetuall motion, would quickly flye away, unlesse it were held in a stronger hold. There is other reason for a veine, as that which contains blood grosse, ponderous and slow of motion. Wherefore if it had acquired a dense and grosse coate, it could scarce bee distributed to the neighbouring parts; God the maker of the universe, foreseeing this, made the coats of the vessels contrary to the consistence of the bodies contained in them. The *Anastomosis* of the veines and Arteryes, that is to say, the application of the mouthes of the one to the other, is very remarkeable, by benefit of which they mutually communicate and draw the matters contained in them, and so also transfuse them by insensible passages, although that *anastomosis* is apparent in the veine and artery that meet together at the joint and bending of the Arme, which I haue sometimes shewed in the Physicke schooles, at such time as I there dissected Anatomyes. Why an Artery is more thicke and dense than a veine.

But the action or function of a muscle is either to move, or confirme the parte according to our will, into which it is implanted; which it doth when it drawes it selfe towards its originall, that is to say, its head. But wee define the head by the insertion of the nerve, which wee understand by the manner of the working of the Muscle. The mutual *Anastomosis* of the veines and arteries.

CHAP. XI.

Of the Muscles of the Epigastrium, or lower belly.

NOW seeing that wee haue taught, what a muscle is, and what the differences thereof are, and what simple and compound parts it hath, and what the use, action and manner of action in each part is; it remaines that wee come to the particular explication of each Muscle, begining with those of the lower belly, as those which we first meet withall in dissection.

These are 8 in number, 4 oblique, 2 on each side, two right or direct one, on the right, another on the left side; and in like manner 2 transverse. All these are alike in force, magnitude and action, so mutually composed, that the oblique descendant of one side, is conjoined with the other oblique descendant on the other side, and so of the rest. Where it is manifest.

We may adde to this number the 2 little Supplying or Assisting muscles which are of a *Pyramidal* forme and arise from the share-bone, above the insertion of the right muscles; Of the oblique muscles of each side the one ascends, the other descends, whereupon it comes to passe, that they are called the Oblique descendant and Ascendant Muscles. Those oblique which wee first meet with, are the descendant, whose substance is partly sanguine, partly spermaticke; for they are fleshy, nervous, ligamentous, veinous, arterious and membranous. Yet the fleshy portion is predominant in them, out of which respect *Hippocrates* is wont to expresse the muscles by the name of fleshes; their greatnes is indifferent betweene the large and the small muscles; their figure 3 square. They are composed of the fore-mentioned parts, they are two From whence a muscle hath its beginning or head.

Their connexion.
Their temperament.
Their action.

The oblique ascendant.

Their site and connexion.

Their Action

The right muscles of the Epigastrium.

Their site.

Originall.

in number; their site is oblique taking their beginning, from the touching of the great saw Muscle and from the sixt and seaventh true ribbes, or rather from the spaces between the sixe lower ribbes, and rather on the forepart of the muscles than of the ribbes themselves, from whence shunning the *Vertebra's* of the loines, the fleshy parts of them are terminated in the externall and upper eminency of the Haunch-bone, and the Membranous end in the lower eminency of the share-bone and the White-line. Yet *Columbus* dissenting from this common description of the oblique Muscles, thinks that they are onely terminated in the White line and not in the share-bone. For (saith he) wherefore should they be inserted into the share-bone which is not moved? But because it would bee an infinite labour and trouble to set downe at large the severall opinions of all Authors of Anatomy, I have thought it sufficient for me to touch them lightly by the way. Their connexion is with the oblique ascendant lying vnder them, and with the direct, or right. Their temperament is twofold, the one hot and moist by reason of the belly and the fleshy portion of them; the other cold & dry in respect of their ligamentous and tendinous portion. Their action is to draw the parts into which they are inserted towards their originall, or els to unite them firmly. Yet each of these privately and properly drawes the hip in an oblique manner towards the *Cartilago Scutiformis* or breast-blade. Then follow the oblique ascendant, who have the same substance, quantity, figure, composure, number and temper the descendant have. They are scituate between the descendant and transverse with whom they have connexion, especially by the vessels which are brought from the parts beneath. All the fleshy parts arise from the rackbones of the Haunch to the ends of the bastard ribs, which they seeme to admit above and below, being fleshy even to the fourth, and then becoming membranous they take their way to the white line, with a double *aponeurôsis*, which passes through the right Muscles above and below, as wee may plainly see from the navill downewards. In their fleshy part they draw their originall from the spine of the Haunch bones a little lower than the descendent end in their fleshy parte. But for their membranous parts, they arise before from the share bone, but behinde from the spondiles of the Holy bone, and *Vertebra's* of the loines obliquely ascending vpwards to the white line, into which they are terminated by an *aponeurôsis* or membranous tendon (which seemes to penetrate the right Muscle vpwards and downewards, especially vnder the navil) but by their fleshy part at the ends of all the bastard ribbes, which they seeme to receive above and below. And because these muscles are terminated in the white line, they have also another use, yet such as is common to all the muscles of the *Epigastrium*, that is, to presse down the Guts. Their action is (if they performe it together) to draw downe the chest, and dilate the breast; but if their actions be separate, they draw the chest to the hip with an oblique motion. After these follow the right muscles, so called because they descend according to the length of the body, & because they have right or streight fibers.

Wee will say nothing (to shunne prolixitie, which in all other places wee will avoid) of their substance and other conditions, which they have common with the fore mentioned Muscles. They are scituate in the eminentest or extuberating region of the belly, bounding the *Epigastrium* taken in generall, (or the superficially belly,) they are devided by the manifest intercourse of the white line, even to the Navell, in which place they seeme to be united even to the place of their insertion. They draw their originall not from the share bone, as some would have it, but according to the insertion of their nerves, from the sides of the *Cartilago scutiformis* & the ends of the sixt seventh and eighth ribs; but they end in the share bone where they make a common tendon sufficiently strong and short. *Sylvius*, *Vesalins* and *Columbus* thinke they arise from the share bone, because they cannot be inserted into that bone, because it is immoveable. You may perceive in these Muscles certaine nervous & transverse intersections, often times three in number for the strength of these Muscles (of which *Galen* makes no mention, although they may be seene in Apes.) And also in the inner side of these muscles you may see foure veines and as many arteryes, of which some creepe upwards, others run downewards. The upper called the Mamillary descend from the Axillarie by the side and lower partes of the *Sternon*, the slenderer portions thereof being distributed

by

by the way, to the *Mediastinum*, and about the fourth and fifth rib to the Dugges, from whence they take their name.

That which remains breaking out by the sides of the Brest-blade inserts it selfe into those muscles creeping along, even almost to the navell; in which place they are manifestly united (that is the veines with the arteries, and arteries with the arteries) with the Epigastricke, which ascend from the vpper part of the Iliackes on each side under the said muscles untill they meet with these 4. mamillary vessels. That you may finde this concurrence of the veines and arteries about the navill, you must follow both the upper and the lower somewhat deepe into the flesh, pressing the blood on both sides from above downwards, and from below upward; untill you shall finde the exosculation of these vessels, which will appeare by this, that the blood will flow from this into that and from that into this, otherwise you can scarce perceiue it, by reason of the smallnes of such vessels which want blood. But that by the benefit of such concurrence of the vessels, the matters may be communicated and transported both from the wombe to the dugs, and againe from the dugs to the wombe, appeares in Nurses, who want their courses, when the milke comes into their dugs, and on the contrary lose their milke when their courses flow plentifully. Otherwise to what purpose should there be such concurrence betweene the vessels of the pappes and wombe, for there are veines and arteries diffused to the sides of the wombe from the roote of the Epigastrickes; for indeed the Epigastrickes which in their ascent meete with the mamillary, goe not to the wombe, though they be next to them, and arise from the same trunk with the Hypogastricke veine of the wombe. The Action of these muscles is, to move or draw neere together the parts of the Hypogastrium to the *præcordia* or Hypochondryes. Their use, in *Columbus* opinion is, to draw the Brest downwards so to dilate it. At the ends of these Nature hath produced two other small Muscles from the upper part of the share bone, of a triangular figure for the safety of the thicke and common tendon of the right Muscles, whereupon they are called *Succenturiati*, or assisters.

The meeting together of the Epigastrick and mamillary veines and arteries.

Their action, Their use.

Some (moved with I know not what reason) would haue these two small Muscles to help the erection of the yeard. *Columbus* thinks they should not be separated from the right, and that they only are the fleshy beginnings of the right. But on the contrary *Fallopins* manifestly proves them different and separate from the right and shewes their use. The Transverse remaine to be spoken of, so called by reason of their fibers which make right angles with the fibers of the right Muscles.

The Pyramidal or assisting muscles.

The transverse muscles of the Epigastrium.

They haue a quadrangular figure situate vpon the greatest part of the *Periosteum*, to which they sticke so close that they scarce can be separated. They take their originall from the production of the loines, the Eminency of the Haunch-bone, the transverse productions of the *vertebra's* of the loynes and the ends of the bastard ribs; contrary to the opinion of many, whom the insertion of the nerve convinces, but they end in the white line, as all the rest doe.

Their figure and site.

Their action is to presse the guts, especially for the expulsion of excrements.

Their Action.

But all the 8 recited Muscles, besides their proper use, haue another common, that is, they stand for a defence or Bulwarke for all the parts lying under them, and serve for the expulsion both of the excrements, infant, and vapours, and also for the strengthening of the voice, as experience shewes in those who sound Trumpets and Cornets.

The common use and action of the eight muscles of the Epigastrium.

Therefore these Muscles doe equally on every side presse the Belly; But the Midriffe, the intercostall Muscles assisting it, doth drive from above downwards, from which conspiring contention followes the excretion of the excrements by the fundament; but unless the Midriffe should assiste, these Muscles would presse the excrements no more downwards, than vppward to the mouth.

Although to this excretion of the excrements, it is not sufficient that the Epigastricke, Midriffe and intercostall Muscles presse the belly, but the Muscles of the throtle must be also shut. For the mouth being open the excrements never goe well forth; because the vapours that passe out of the

Why when the mouth is open the excrements go more slowly forth,

Why when the mouth is open the excrements go more slowly forth.

mouth, which being restrained and driven to the Midriff, by stretching it powerfully thrusts downe the excrement. Wherefore Apothecaries when they give glisters, bid the Patient to open his mouth, that the glisters may easly goe up, which otherwise would scarcely go up, the mouth being shut, because so we should have no place empty in us, into which the glyster might be admitted.

The first Figure of the Lower belly.

 1, 2. The place wherein the right Muscles arise, which being here cut off, do hang down, that their Vessels may the better be scene.
 3, 4. The *Anastomosis* or inoculation of the foresaid Vessels, making the consent of the *Abdomen* and the Nose, & of the Wombe with the Breasts, as some think.
 LL. Branches of Veines running into the sides of the *Peritonæum*.
 N. The place of the Haunch Bone bared, to which the Oblique and the Transverse Muscles doe grow.

Of the whiteline, and *Peritonæum* or Rim of the belly.

What the whiteline is

What the *Peritonæum* is.

The substance and quantity.

The white line is nothing els, than the bound and extremities of the Muscles of the *Epigastrium* distinguishing the belly in the middest into two parts, the right and left. It is called white, both of its owne colour, and also for that no fleshy part lyes vnder it, or is placed above it. It is broader above the navill, but narrower below, because the right muscles doe there grow into one, Now we must treat of the Coat or membrane, *Peritonæum* or Rim of the belly; it is so called, because it is stretched over all the lower belly, and particularly over all the parts contained in the ventricle, to which also it freely lends a common coat. It hath a spermaticke substance as all other membranes have; the quantity of it in thicknes is very small, (for it is almost as thin as a spiders web) yet differing in divers places in men, and women; for men have it more thick and strong about the Navil, that so it may containe the extension of the stomacke, often stretched beyond measure with meat and drinke. On the contrary women have it so thick and strong below their navell that it seemes double, that so they may more easily endure the distention of their wombe caused by the child contained in it. But above the navell men and women have the *Peritonæum* of an equall strength, for the selfe same reason. The longitude and latitude of it is knowne by the circumscription of the belly.

The figure is round and some what long; it puts forth some productions, like finger stalles, both for the leading and strengthening the spermaticke vessels and the *Cremaster* muscles of the Testicles, and besides it the ejaculatory vessels, as also to impart a coat to the testicles and all the naturall parts.

The figure.

It is composed of slender, membranous and nervous fibers, certaine smalle branches of veines and arteries concurring with them, which it receiues for life and nourishment from the adherent parts.

The composition.

This membrane is one in number, and besides every where one and equall, although *Galen* would haue it perforated in that place where the spermaticke vessels descend to the Testicles; But in truth we must not thinke that a hole; but rather a production as we said before.

The number.

Lib. de sem.

The latter Anatomists haue observed, the Coate *Peritoneum* is doubled below the Navell, and that by the spaces of these reduplications the vmbilicall arteries ascend to the Navell.

It is situate nere the naturall parts and compasses them about, and joined by the coat; which it giues them, as also on the sides, it is ioyned to the *vertebra's* of the loines, from whose ligaments, (or rather periostium) it takes the originall: on the lower part it cleaves to the share bone, and on the upper to the midriffe whose lower parte it wholly invests; on the fore or outer parte it stickes so close to the transverse muscles, that it cannot bee pluckt from them but by force; by reason of the complication and adhesion of the fibers thereof with the fibers of the proper membrane of these muscles, which membrane in *Galen's* opinion proceeds from this *Peritoneum*, that so it is no marvaile that we may more easily breake, than separate these two coats. It is of temperature cold and dry, as all other membranes are.

The site and connexion.

It hath many uses, the first whercof is, to invest and cover all the parts of the lower belly, specially the kall, least it should be squeezed by great compressures and violent attempts into the empty spaces of the muscles, as it sometimes happens in the wounds of the *Epigastrium*, unles the lips of the ulcer bee very well united: for then appears a tumor about the wound by the Guts and kall thrusting without the *Peritoneum* into those spaces of the muscles; from whence proceeds cruell paine.

Lib. 6. Met.

Vie.

Another vse is to further the casting forth of the excrements by pressing the ventricle and gutson the foreside, as the Midriffe doth above, as one should doe it by both their hands joyned together.

The third use is, it prohibits the repletion of the parts with flatulency after the expulsion of the excrements, by straitening and pressing them downe.

The fourth and last is, that it contains all the parts in their seat and bindes them to the backe-bone, principally that they should not flye out of their places by violent motions, as leaping and falling from on high.

Lastly wee must know, that the Rim is of that nature that it will easily dilate it selfe, as wee see in Dropsies, in women with child, and in tumors against nature.

CHAP. XIII.

Of the Epiploon, Omentum, or Zirbus, that is the Kall.

After the containing parts, follow the contained, the first of which is the *Epiploon*, (or Kall) so called, because it as it were swims upon all the guts.

The substance, magnitude, figure.

The substance of it is fatty and spermaticke, the quantity of it for thickness is diverse in diverse men according to their temperament. The latitude of it is described by the quantity of the guts. It is in figure like a Purse, because it is double. It is composed of veines, arteries, fat and a membrane, which sliding downe from the gibbous part of the ventricle, and the flat part of the Gut *Duodenum* and spleen over the Guts, is turned backe from the lower belly to the top of the Colon. It is one as wee said covering the Guts. It hath its cheefe connexion

conception.

nexion with the first *Vertebra's* of the loines, from which place in beasts it seemes to take a coate, as in men from the hollow part of the spleene and gibbous of the ventricle and depressed part of the *Duodenum*, from whence doubled it is terminated in the fore and higher part of the Collicke gut. Which moved *Galen* to write that the upper part of the membrane of the Kall was annexed to the ventricle, but the lower, to the laxer part of the Collicke Gut. From the vessells of which parts it borrowes his, as also the nerves, if it have any. The temper of it in leane bodyes is cold and dry, because their Kall is without fat; but in fat bodyes it is cold and moiste by reason of the fat. The use of it is two-fold: The first is to heat and moisten the Guts, and help their concoction, although it doe it by accident, as that which through the density of the fatte hinders the cold aire from piercing in, and also forbiddes the dissipation of the internal heat. Another use is, that in want of nourishment in times of great famine, for sometimes it cherishes, and as it were by its dew preserves the innate heate both of the ventricle and the neighbouring parts, as it is written by *Galen*. Moreover wee must observe, that in a rupture or relaxation of the *Peritonaeum* the Kall falls downe into the *scrotum*, from whence comes that rupture wee call, *Epiptocoele*. But in weomen that are somewhat more fat it thrusts it selfe betweene the bladder and the necke of the wombe, and by its compression hinders, that the seed comes not with full force into the wombe, and so frustrates the conception. Besides, when by a wound or some other chance, any part of it be defective, then that part of the belly which answers to it, will afterwards remaine cold and raw, by reason of the forementioned causes.

The second figure of the lower belly.

CHAP.

CHAP. XIII.

Of the Ventricle or Stomacke.

Now we must speake of the Stomacke, the receptacle of the food necessarie for the whole body, the seate of appetite, by reason of the nerves disperfed into its upper orifice, and so into its whole substance. The substance thereof is rather spermatike than sanguine, because that for one fleshie membrane, it hath two nervous; The quantitie or magnitude of the ventricle is diverse, according to the various magnitude of bodies, and gluttony of men. The figure of it is round and somewhat long, like a Bagpipe. The stomacke is composed of two proper coates, and one common from the *Peritoneum*, together with veines, sinewes, and arteries; the innermost of its proper coates is membranous woven with right fibers, for the attraction of meates, it is extended and propagated even to the mouth thereof, whereby it comes to passe that the affections of one part may easily be communicated to the other by sympathy, or consent. This coate hath its originall from the membranes of the braine which accompany the nerves descending from the third and fourth conjugation to the mouth thereof. And in like sort from other productions descending by the passages of the head, from whence also another reason may be drawne from that, which they commonly bring from the nerves of the sixth conjugation; why in wounds of the head, the stomacke doth so soone suffer by consent with the braine. The exterior, or outer is more fleshie and thicke, woven with oblique fibers, to retaine and expell. It drawes it originall from the *Pericranium*, which as soone as it comes to the gullet, takes unto it certaine fleshie fibers. There be nerves sent into the stomacke from the sixth conjugation of the braine, as it shall be shewed in its proper place. Veines and arteries are spread into it from the *Gastrica*, the *Gastrepiploides*, the *Coronaria* and splenicke, from the second, third, and fourth distribution of the *vena Porta*, or gate-veine; and the third of the descendend artery to the naturall parts, as soone as it passes forth of the midriffe.

What the ventricle is.

The substance

The magnitude.

The figure.
The composition.

The cause of the consent of the mouth and stomacke.

It is one in number. The greater part of it is situated on the left side betweene the spleene, the hollownesse of the liver, and the guts, that assisted by the heate of such neighbouring parts, it may more cheerefully performe the concoction of the meate. Neither am I ignorant that *Galen* hath written, that a great part of the stomacke lies on the left side. But inspection it selfe, and reason makes me derogate from *Galen's* authority, for because there is more emptie space on the left side, by reason the spleene is lesse than the liver, it was fit it should lie more on the left side. The more proper connexion of it is with the gullet and guts, by its two orifices; with the braine by its nerves; with the liver and spleene by its veines; with the heart by its arteries; and with all the naturall parts by its common membrane.

The number.

Lib. 4. de usu partium.

The connexion.

The temper of the ventricle in men of good habite, is temperate, because it is almost composed of the equall commixture of sanguine and spermatike parts; or according to *Galen's* opinion, it is cold of its selfe, and by the parts composing it; and hot by the vicinitie of the bowels. But in some it is hotter, in others colder, according to the diverse temper and complexion of diverse bodies. That stomacke is to bee thought well tempered, that powerfully drawes downe the meate and drinke, and embraces and retaines them so drawne, untill by concoction and elixation, they shall be turned into a juyce like creame (which the Greekes call *Chylos*;) and lastly, which doth strongly send from it, and repell the excrements of this first concoction.

The temper.

Lib. 9. Meth.

The stomacke is knowne to be hotter by this, that it better concocts and digests course and hard meates, as beefe, hard egges, and the like, than soft meates easie of digestion, which it corrupts and turnes into belchings. For so a young chicken, is sooner burnt than well roasted at a great fire. The stomacke which is colder, desires much meate, but is slow in concocting them, especially if they be cold and hard of digestion, which for that cause quickly turne sowre. The action of a well conditioned stomacke, is twofold, one common, another proper. The common is to attenuate mixe and digest the meates taken in at the mouth, for the nutrition of it selfe and

Notes of a hot stomacke.

The action twofold.

and the whole body, after the liver hath performed its dutie, which before it be done, the ventricle onely enjoys the sweet pleasure of the *Chylus*, and comforts its selfe against the heate and impuritie of the adjacent parts, wherefore it is called the worke-house of concoction. Its first action is to attract, retaine, and assimilate to it selfe that which is convenient; but to expell whatsoever shall be contrary, either in quantitie, or qualitie, or in the whole substance.

The two orifices of the stomacke.

It hath two orifices, one above, which they commonly call the stomacke and heart, the other lower, which is called the *Pylorus*, or lower mouth of the stomacke. The upper bends to the left side neere the backe bone; it is farre more large and capacious than the lower, that so it may more commodiously receive meates halfe chewed, hard and grosse, which Gluttons cast downe with great greedinesse; it hath an exquisite sense of feeling, because it is the seate of the appetite, by reason of the nerves incompassing this orifice, with their mutuall embracings; whereby it happens that the ventricle in that part is endued with a quicke sense, that perceiving the want and emptinesse of meate, it may stirre up the creature to seeke foode. For albeit nature hath bestowed foure faculties on other parts, yet they are not sensible of their wants, but are onely nourished by the continuall sucking of the veines, as plants by juice drawne from the earth.

The site.

This orifice is seated at the fifth *Vertebra* of the chest, upon which they say it almost rests. Yet I had rather say that it lies upon the twelfth *Vertebra* of the chest, and the first of the loines; for in this place the gullet perforates the midriffe, and makes this upper orifice. The lower orifice bends rather to the right side of the body, under the cavitie of the liver. It is farre straiter than the upper, lest any thing should passe away before it bee well attenuated and concocted; and it doth that by the helpe or assistance of, as it were a certaine ring, like to the sphincter muscle of the fundament, which some have thought a glandule made by the transposition of the inner and fleshie membrane of the ventricle into that which is the outer of the guts. I know *Columbus* laughs at this glandulous ring, but any one that lookes more attentively shall perceive that the *Pylorus* is glandulous. The stomacke in its lower and inner side, hath many folds and wrinkles, which serve to hold and containe the meates, untill they be perfectly concocted. In the ventricle wee observe parts gibbous and hollow; the hollow is next to the liver and midriffe; the gibbous is towards the guts. Now we must note, that the ventricle when it is much resolved or loosed, may slide downe even to the navell neare the bladder, the which wee have observed in some bodies dissected after their death.

The glandulous ring of the *Pylorus*.

The falling downe of the stomacke.

R. the passage of the bladder of the gall into the *Duodenum* at R. S, a glandulous body growing under the *Duodenum*, bearing up the vessels. X. Y. a nerve on the left side creeping up to the top of the stomacke, and so running out to the liver.

CHAP. XV.

Of the Guts.

 He Guts the instruments of distribution and expulsion, are of the same substance and composure with the stomacke, but that the site of the coates of the stomacke is contrarie to those of the guts. For that which is the innermost coate of the stomacke is the outermost of the guts, and so on the contrary. The figure of the guts is round, hollow and capacious, some more, some lesse according to the diverse bignesse.

But for the quantitie of the guts, some are small, some great, more or lesse, according to the varietie of bodies. But they are fixe in number, for there be three small; the *Duodenum*, the *Iejunum*, or empty gut, and the *Ilium*. Three great, the Blind, the Collicke, and the Right gut. All which have had their names for the following reasons; the first, because it is extended the length of twelve fingers, like another stomacke, without any turning, or winding; of which greatnesse it is found in great bodied men, such as were more frequently to be met withall in *Galens* time, than in this time of ours, in which this gut is found no longer than seven, eight, or nine fingers at the most. The cause of this length is, that there may be a free passage to the gate veine, comming out of the liver, as also to the artery and nerve which runne into it. For seeing that this gut may sometimes rise to the top of the liver, it would possesse the space under the bladder of the gall (with which it is often tintured) if it had any revolutions that way, which is the passage for such like vessels. Others give another reason of this figure, which is, that there should bee nothing to hinder the easie and fit distribution of the perfectly concocted *Chylus* to the liver.

The second is called *Iejunum*, or the empty gut, not because it is absolutely so, but because it containes little in comparison of the other. There is a triple cause of this emptines, the first the multitude of the meseraick veines and arteryes which are about it, whereupon there is a greater and quicker distribution of the *Chylus*. The second is the vicinity or neighbourhood of the liver strongly drawing the *Chylus* contained in it; the third is the flowing downe of the cholericke humor from the bladder of

of the Gall into it, which ever and anon by its acrimony cleanses away the filth, and by continuall flowing sollicites it to expulsion. The third is called *Ileon* because it lyes betweene the *Ilia* or flanks, it differs nothing from the rest in substance and magnitude, but in this one thing, that there is more matter contained in it than in the rest, by reason of the paucity of the vessels terminated in it, that it is no marvell that there can be no exact demonstration made of them. The fourth is called *Cacum* or the Blind, because it hath but one passage to send out and receive in the matter. This gut hath a long and strait production, which according to the opinion of some (though altogether erroneous) often falls downe into the *Scrotum* in the rupture, or relaxation of the Rim of the Belly; for that production in the lower belly strongly stickes to the *Peritoneum* or Rim, which hinders such falling downe. But *Galen* seemes by such a blind gut to have meant this long and narrow production, and certainly so thinkes the common sort of Anatomists, but here *Vesalius* justly reprehended *Galen*. Wherefore *Sylvius* that he might free *Galen* of this fault, would haue us by the blind gut to understand the beginning of the collicke gut. The fift is called *Colon* (or collicke gut) because it is greater and more capacious than the rest. The sixt and last, the Right gut, by reason of the rightnes or straightnes of the passage. This in beasts especially, hath a certaine fatnesse in it to make the passage slippery, and lest the gut should be exulcerated in the passage, by the sharpenesse of hard and acrid excrements.

The site of these guts is thus, The *Duodenum* upon the backebone bends to the right hand; the *Ieiunum* possesses a great part of the upper umbilicall region, diffuses it selfe into both sides with windings, like to these of the gut *Ileon*, even to the flanks. The gut *Ileon* is situate at the lower part of the umbilicall region, going with many turnings and windings, even to the hollownes of the holy-bone above the bladder and side parts of the *Hypogastrium*, which they call the flanks.

The Blind bends to the right hand, a little below the kidney, above the first and fourth *Vertebra* of the loines. The Colon or Collicke gut is crooked and bent, in the forme of a Scythian bow, filling all the space from the blind gut, below the right kidney, even to the hollownes of the liver, and then it goes by the gibbous part of the stomacke above the small guts, even to the hollownesse of the spleene; from whence sliding under the left kidney, with some turnings, it is terminated upon the *Vertebra's* of the loines.

The distinction
on betweene
the collicke
and the stone
in the kidneys.
Their con-
nexion,

By all which turnings and windings of the collicke gut, it is easie to distinguish the paine of the stone of the kidneys, which remaines fixt in one certaine place, from the collicke wandring through these crooked passages we mentioned. The right gut tends with an oblique site towards the left hand, upon the holy bone even to the very fundament. They have all one and a common connexion, for they are all mutually joined together by their coats, because there is but one way from the gullet even to the fundament, but they are joynd to the principall parts by their nerves, veines, and arteries.

But a more proper connexion is that, where the *Duodenum* on the upper part of it, is joynd with the *Pylorus*; but on the lower part, to the *Ieiunum*, and the parts lying under it, by the coate of the *Peritoneum*. The *Ieiunum*, or emptie gut, is joynd to the *Duodenum* and *Ileon*. The *Ileon* with the emprie and blind guts. The blind with the *Ileon* and *Colon*, and with the right side of the backebone where it is tied more straitly. The *Colon* with the blind and right guts, and in his middle part, with the kidneys and the gibbous part of the stomacke; whereby it comes to passe, that being distended with wind in the collicke, it overturnes and presses the stomacke, and so causes vomiting.

Why vomiting
happens in the
collicke.

The *Sphincter*
muscles of the
fundament.

*Gal. lib. 5. de
usurpationum.
cap. 14.*

Lastly, the right gut is annexed with the collicke gut and fundament. At the end whereof there is a muscle fastened, of figure round and circular called the *Sphincter*, arising from the lower *Vertebra's* of the holy bone and rump, by the benefit of which as of a dore or gate, the excrements are restrained at our will, lest man borne for all honest actions, without all shame, in every time and place, should be forced every where to ease his belly. For such as have lost the benefit of this muscle by the palsy, have their excrements goe from them against their wills. There is a body situate at

at the end of the right gut, of a middle substance betweene the skinned and flesh, as it were arising from the mixture of them both, like the extremities of the lippes, of the same use with the *Sphincter*, but that it is not altogether so powerfull. But there are also certaine veines situate about it called the *Hæmorrhoidall*, of which we will speake in their place.

Besides, there are two other muscles that descend to the end of this gut, being broad and membranous on each side, one arising from the side and inner parts of the share and hippe-bones, which inserted above the *Sphincter* pull up the fundament falling downe, wherefore they are called *Levatores Ani*, or the lifters up of the fundament. Wherefore when as either they are too weake, or resolved, or the fundament oppressed with the weight of flegmaticke, salt, chollericke and sharpe humors, the gut is scarce restored into its place, that there is neede of the helpe of the fingers for that purpose.

The guts follow the temper of the stomacke. Their action is the distribution of the *Chylus* by the meieraicke veines (which of dutie belongs to the three small guts) and the receiving the excrements of the *Chylus*, and retention of them, till a fit time of expulsion, which belongs to the third quarter. Besides, these small guts finish up the worke of concoction, begun in the stomacke, although they be not altogether made for that use. But nature is often accustomed to abuse the parts of the body for some better use.

The fifth figure of the lower belly.

A. The brest blade, *Cartilago Ensisformis*.

BB. The Rim, with the midriffe and broken ribs bent outwards.

CC. the gibbous part of the liver.

D. a ligament tying the liver to the midriffe.

E. part of the umbilicall veine.

FF. the stomacke filld full of meate.

G. a part of the spleene.

H. the blind gut of the late writers, for the Ancients tooke the toppe of the colon for it.

I. the beginning of the great or thicke guts.

I. and so to K. sheweth the passages of the collicke gut from the right kidney to the liver. And so the collicke and the stone on this side are in one place, and therefore hardly distinguished.

K. to L. the same collicke gut lieth under the whole bottome of the stomacke, which is the reason that those which are troubled with the collicke cast so much.

L. to M. The passage of the Colon

from the spleene to the share bone, by the left kidney, a way, which maketh the paine of the stone and the Collick on the left side very hard to distinguish. N. The Colon ending in the right gut. O. The beginning of the right gut unto the bladder. P. Q. The sunken or fallen side of the Colon at P. and his Chambers or Cells at Q. R. S. T. The lesser guts, especially lying under the Navil. a. a. The two umbilicall arteryes. b. The bottome of the bladder. * The connexion of the bladder and the Perito-

But

Their fibers.

But we must note, that for the compofure of the guts, they have onely tranfverfe fibers, for expulfions fake, unleffe that at the beginning of the *Colon*, and the end of the right gut, you may fee certaine right fibers added to the tranfverfe to ftrengthen them, leff thefe guts fhould chance to be broken and torne by the paffage of hard excrements, and the laborious endeavour of expulfion (fpecially in brute beafts.)

How the guts become fit to retaining.

But if any afke, how they have retention, being they want oblique fibers, he may know that the *feces* are retained in the right gut, by the force of the *Sphincter* mufcle, but oft times in the blind, by their hardneffe and abundance, whereby they fticke in the paffage; but in the reft, by reafon of their conformation into many windings and turnings.

Their length.

The length of the guts, is feven times more than the length of the whole body; to this length they have windings, leaft the nourifhment fhould quickly flide away, and leaft men fhould bee withdrawne by gluttony from action and contemplation. For fo wee fee it comes to paffe in moft beafts, which have one Gut, ftretched ftraight out from the ftomacke to the fundament; as in the *Lynx* and fuch other beafts of infatiable gluttony, alwayes, like plants, regarding their food.

CHAP. XVI.

Of the Mefentery.

The Substance
magnitude.

Figure.
Composure.

Frer the Guts follows the Mefentery, being partly of a fatty and partly of a fpermatricke fubftance. The greatneffe of it is apparent enough, although in fome it be bigger, and in fome leffer according to the greatneffe of the body. It is of a round figure and not very thicke. It is compofed of a double coate arifing from the beginning and roote of the *peritoneum*. In the midft thereof it admits nerves from the *Coftall* of the fixt conjugation, veines from the *Vena Porta* or Gate veine; Arteries from the descendant artery, over and befides a great quantity of fat and many glandulous bodyes, to prop vp the divifion of the veffels fpred over it, as alfo to moiften their fubftance. It is in number one, fcituate in the middle of the guts, from whence it tooke its name. Yet fome divide it into two parts, to wit, into the *Meferaum*, that is, the portion interwoven with the fmall guts, and into the *Mefocolon* which is joined with the Great. It hath connexion by its veffels with the principall parts, by its whole fubftance with the guts, and in fome fort with the kidneies, from whole region it feemes to take its coats.

Number.

The connexion.

The temper.

It is of a cold and moift temper, if you have refpect to his fatty fubftance; but if to the reft of the parts, cold and drye.

The action
and ufe.

The action and ufe of it is, to bind and hold together the guts, each in his place, leaft they fhould rafhly be folded together; and by the Meferaicke veines (which they terme the hands of the Liver) carry the *Chylus* to the liver.

All the meferaicke
veines come from the
liver.

In which you must note, that all the Meferaicke veines come from the liver, as we underftand by the diffection of bodyes; although fome have affirmed, that there bee fome veines ferving for the nourifhment of the guts, no wayes appertaining to the Liver, but which end in certaine Glandulous bodyes, difperfed through the Mefentery, of whole ufe we will treat hereafter.

CHAP. XVII.

Of the Glandules in generall, and of the Pancreas, or sweet bread.

Substance of
the glandules.

Quantitie and
figure.

Glandule is a fimple part of the body, fometimes of a fpongye and foft fubftance, fometimes of a dense and hard. Of the foft Glandules are the *Tonfilla*, or Almonds, like in fubftance to blanched Almonds; the *Thymus*, *Pancreas*, *Testicles*, *Proftata*. But the dense and hard are the *Parotides* and other like. The Glandules differ amongst themfelves in quantity and figure, for fome are greater than other fome, and fome are round and others plaine, as the *Thymus* and *Pancreas*. Others

Others are compounded of veines, nerves, arteries, and their proper flesh, as the Almonds of the eares, the milkie glandules in the breasts and the testicles. Others want nerves, at least which may be seene, as the *Parotides*, the axillarie, or those under the armeholes and others. The number of glandules is uncertaine, by reason of the infinite multitude and variety of sporting nature. You shall finde them alwayes in these places, where the great divisions of vessels are made; as in the middle ventricule of the braine, in the upper part of the Chest, in the Mesentery and other lik places.

Although other some be seated in such places, as nature thinkes needfull to generate and cast forth of them a profitable humor to the creature; as the almonds at the roots of the tongue, the kernells in the dugs, the spermatick vessels in the *scrotum* and at the sides of the wombe; or where nature hath decreed to make emunctories for the principall parts, as behind the eares, under the armeholes, and in the groines. The connexion of glandules is not only with the vessels of the parts concurring to their composition, but also with those, whose division they keep and preserve. They are of a cold temper, wherefore Physicians say the blood *retrudescere*, (i) to become raw againe in the dugs, when it takes upon it the forme of milke. But of these some have action, as the almonds, which poure our spattle usefull for the whole mouth, the dugs milke, the Testicles seed; others, use onely as those which are made to preserve, vnderprop and fill vp the divisions of the vessels. Beside this we have spoken of glandules in generall, we must know that the *Pancreas* is a glandulous and flesh-like body, as that which hath every where the shape and resemblance of flesh. It is situate at the flat end of the liver, under the *Duodenum* with which it hath great connexion, and under the gate-veine, to serve as a bulwarke, both to it and the divisions thereof, whilst it fills up the emptie spaces, betweene the vessels themselves, and so hinders, that they be not pluckt asunder, nor hurt by any violent motion, as a fall, or the like.

Composition.

The size.

CHAP. XVIII.

Of the Liver.

Having gone thus farre, order of dissection now requires, that we should treat of the distribution of the gate veine; but because it cannot well be understood unlesse all the nature of the liver from whence it arises, be well knowne, therefore putting it off to a more fit place, we will now speake of the Liver. Wherefore the liver (according to *Galens* opinion, *lib. de form. fetus*) is the first of all the parts of the body, which is finished in conformation, it is the shoppe and Author of the bloud, and the originall of the veines; the substance of it, is like the concrete mudde of the bloud, the quantitie of it is diverse, not onely in bodies of different, but also of the same species; as in men amongst themselves, of whom one will bee gluttonous and fearefull, another bold, and temperate, or sober; for hee shall have a greater liver than this, because it must receive and concoct a greater quantitie of *Chylus*: yet the liver is great in all men, because they have need of a great quantitie of bloud for the repairing of so many spirits & the substantifick moisture, which are resolved and dissipated in every moment by action and contemplation. But there may bee a twofold reason given, why such as are fearefull have a larger liver. The first, is because in those the vitall facultie (in which the heate of courage and anger resides) which is in the heart, is weake; and therefore the defect of it must be supplied by the strength of the naturall facultie. For thus nature is accustomed to recompence that which is wanting in one part, by the increase and accession of another. The other reason is, because cold men have a great appetite, for by *Galens* opinion *In arte parva*, coldnesse increases the appetite; by which it comes to passe that they have a greater quantitie of *Chylus*, by which plenty the liver is nourished, and growes larger. Some beasts, as Dogges, and swine, have the liver divided into five or more Lobes, but a man hath but one Lobe, or two, or three at the most; and these not so much distinguished, as which chearish the upper and hollow region of the ventricule, with embracing to helpe forward the worke of concoction. Therefore the liver is almost content with one Lobe, although it is alwayes rent with a small division, that the umbilicall veine pearcing into the roots and substance of it, may have a free passage; but also oftentimes there is as it were a certaine small lobe of the liver, laid under the umbilicall veine, as a cushion.

What the liver is.

Its substance and quantity.

Why cowardes have great livers.

L

The

The figure.

The figure of the liver is gibbous; rising up and smooth towards the Midriff, towards the stomacke is the *sinuous* or hollow side of it somewhat unequall, and rough by reason of the distance of the Lobes, the originall of the hollow veine, and the site of the bladder of the Gall.

The composition.
The vessels.

The composition of the liver is of veines, nerves, arteryes, the coate and proper substance thereof which we call the grosse and concreet blood, or *Parenchyma*. Veines and arteryes come to it from the navell; but nerves immediatly from these which are diffused over the stomack according to *Hippocrates*; yet they penetrate not very deep into its substance, for it seemes not to stand in neede of such exact sense, but they are distributed upon the coate and surface thereof, because this part made for distribution over the whole body, keepe to it selfe no acrid or maligne humor, for the perception of which it should neede a nerve, although the coate investing it, sends many nervous fibers into its substance, as is apparent by the taking away of the coate from a boiled liver; we must thinke the same of the other entrals. The coate of the liver is from the *Peritoneum*, waxing small from the umbilicall veine, when it divides it selfe for the generation of the gate and hollow veines, as is observed by *Galen*, *lib. de format.*

The number and site.
The connexion.

Fetus. The liver is onely one, situate in the greater part on the right side, but with the lesser part on the left, quite contrary to the stomacke. Its chiefe connexion is with the stomacke, and guts, by the veines and membranes of the *Peritoneum*; by the howllow veine and artery, with the heart; by the nerve with the braine, and by the

The temper.

same ligatures with all the parts of the whole body. It is of a hot and moist temper, and such as have it more hot, have large veines and hot blood; but such as have it cold,

The action.

have small veines, and a discoloured hew. The Action of the Liver is the conversion of the *Chylus* into blood, the worke of the second concoction. For although the *Chylus* entring into the meseraicke veines, receive some resemblance of blood, yet it acquires not the forme and perfection of blood, before it be elaborate,

The ligaments

and fully concoct in the liver. It is bound and tied with three strong ligaments, two on the sides in the midst of the bastard ribs, to beare up its sides, and the third more high and strong, descending from the breast-blade, to sustaine its proper part, which with its weight would presse the lower orifice of the stomacke, and so cause a falling or drawing downe of the sternon and collar bone. And thus much may suffice for its proper ligaments, for we before mentioned its common, the veines, arteries, nerves, and coate of the *Peritoneum*, by which it is knit to the loines, and other naturall parts. But wee must note, that besides these three proper ligaments, the liver is also bound with others to the bastard ribs, as *Sylvius* observes in his Anatomieall observations, and *Hollerius* in his *Practise*, *Cap. de Pleuritide*.

CHAP. XIX.

Of the bladder of the Gall.

The substance, greatness, and figure thereof.
The composition.

Now wee must come to the bladder of the Gall, which is of a nervous substance, and of the bignesse of a small peare; it is of figure round, with the bottome more large, but the sides and mouth more narrow and strait. It is composed of a double coate, one proper, consisting of three sorts of fibers, the other from the *peritoneum*. It hath a veine from the *Porta* or gate veine, and an artery from that which is diffused into the liver, and a nerve from the sixth conjugation. It is but one and that hid on the right side under the greater lobe of the liver, it is knit with the touching of its own body, and of the passages and channels made for the performance of its actions with the liver, and in like manner with the *Duodenum*, and not seldome with the stomack also, by another passage; & to conclude to all the parts by its veines, nerves, arteries, and common coate. It is of a cold temper, as every nervous part is.

Temper.

Action.

The action of it is to separate from the liver the cholericke humor, and that excrementitious, but yet naturall by the helpe of the right fibers, for the purifying of the blood, and by the oblique fibers, so long to keepe it being drawne, untill it begin to become troublesome in quantitie, qualitie, or its whole substance, and then by the transverse fibers, to put it downe into the *Duodenum* to provoke the expulsive facultie of the guts. I know *Fallopins* denies the texture of so many fibers, to be the minister of such action to the gall. But *Vesalins* seemes sufficiently to have answered him

him. The bladder of the gall hath divers channels, for comming with a narrow necke, even to the beginning of the gate veine, it is divided into two passages, the one whereof suffering no division is carried into the *Duodenum*, vnlesse that in some it send another branch into the bottome of the stomack, as is observed by *Galen*; which men have a miserable and wretched life, being subject to cholericke vomitings, especially when their stomackes are empty, with great paines of their stomacke and head, as is also observed by *Galen Cap. 74. Artis Med.* The other comming out of the body of the liver devides it selfe into two or three passages, againe entering the substance of the liver, is divided with infinite branches, accompanying so many branches of the gate veine through the substance of the liver, that so the blood vnlesse it be most elaborate and pure, may not rise into the hollow veine, all which things Dissection doth manifestly teach.

CHAP. XX.

Of the spleene or Milt.

BVt because we cannot well shew the distribution of the gate veine, vnlesse the spleene be first taken away, and removed from its seate: therefore before we go any further, I have thought good to treat of the spleene. Therefore the spleene is of a soft, rare, and spongiouse substance (whereby it might more easily receive and drinke up the dreggs of the blood from the liver) and of a flesh more blacke than the liver. For it resembles the colour of its muddy blood, from which it is generated. It is of an indifferent greatnesse, but bigger in some, than in other some, according to the diverse temper and complexion of men. It hath, as it were, a triangular figure, gibbous on that part, it stickes to the ribbes and midriffe, but hollow on that part next the stomacke. It is composed of a coate, the proper flesh, a veine, artery, and nerve. The membrane comes from the *peritoneum*, the proper flesh from the *feces* or dregges of blood, or rather of the naturall melancholy humor, with which it is nourished. The fourth branch of the *vena porta*, or gate veine, lends it a veine; the first branch of the great descendant artery presently after the first entrance without the Midriffe, lends it an arterie. But it receives a nerve from the left costall, from the sixth conjugation on the inner part, by the rootes of the ribs; & we may manifestly see this nerve, not only dispersing it selfe through the coate of the liver, but also penetrating with its vessels the proper flesh thereof, after the selfesame manner, as we see it is in the heart and lungs. It is one in number, situate on the left side, betweene the stomacke and the bastard ribs, or rather the midriffe which descend to their rootes. For it oft times cleaves to the midriffe on its gibbous part, by a coate from the *peritoneum*, as also on the hollow part to the stomacke, both by certaine veines which sends it into the ventricle, as also by the kall. It hath connexion, either primarily, or secundarily, with all the parts of the body, by these its vessels.

ale.

It is of a cold and drie temper; the action and use of it is to separate the melanchollicke humor, which being feculent and droffie, may be attenuated by the force of many arteries dispersed through its substance. For by their continuall motion, and native heate, which they carrie in full force with them from the heart, that grosse blood puts off its grossenesse, which the spleene sends away by passages fit for that purpose, retaining the subtler portion for its nourishment. The passages by which it purges it selfe from the grossenesse of the melancholy blood, are a veine ascending from it into the stomacke to stirre up the appetite by its sourenesse, and strengthen the substance thereof by its astringion; and also another veine, which sometimes from the spleene branch, sometimes from the gate veine, plainly under its orifice, descends to the fundament, there to make the Hæmorrhoidall veines.

The gate-veine, as also all the other veines, is of a spermaticke substance, of a manifest largenesse, of a round and hollow figure, like to a pipe or quill. It is composed of its proper coate, and one common from the *peritonaum*. It is onely one, and that situate in the simous or hollow part of the liver, from whence it breakes forth (or rather out of the umbilicall veine) into the midst of all the gurs, with which it hath connexion, as also with the stomacke, spleen, *sphincter* of the fundament and *Peritonaum*, by the coat which it receives from thence. It is of a cold and dry temper. The Action of it is, to sucke the *Chylus* out of the ventricle and guts, and so to take and carry it to the Liver, untill it may carry back the same turned into blood for the nutriment of the stomacke, spleen and guts. This Gate veine comming out of the simous part of the liver, is divided into fixe branches, that is 4 simple and two compound, againe divided into many other branches. The first of the simple ascends from the fore part of the truncke to the bladder of the Gall by the passage of the Choller (and are marked with g. g.) with a like arterye for life and nourishment, and this distribution is knowne by the name of the *Cystica gemella* or Cysticke twins. The second is called the *Gastrica* or stomack veine arising in like manner from the fore part of the truncke, is carried to the *Pylorus* and the simous or backe part of the stomacke next to it.

The third is called *Gastropiplois*, the stomacke and kall veine, which comming from the right side of the gate veine goes to the gibbous part of the stomacke next to the *Pylorus* and the right side of the kall.

The fourth going forth from behind and on the right hand of the gate veine, ascends above the roote of the Meseraicke branch, even to the beginning of the gut *Jejunum*, along the gut *Duodenum*, from whence it is called *Intestinalis*, or the gut-veine. And these are the foure simple branches. Now we will speake of the compound.

The first is the spleenicke, which is divided after the following manner. For in its first beginning and upper part, it sends forth the *Coronalis*, or crowne veine of the stomacke, which by the backe part of the stomacke ascends into the upper and hollow part thereof; to which place, as soone as it arrives, it is divided againe into two branches, the one whereof climbs up even to its higher orifice, the other descends downe to the lower, sending forth by the way other branches to the fore and backe parts of the stomacke. These engirt and on every side incompass the body of the ventricle, for which cause they are named the crowne veines.

I have sometime observed this comming forth of the truncke, a little above the orifice of the spleenicke branch. But this same spleenicke branch on its lower part, produces the branch of the Hæmorrhoidall veines, which descending to the fundament above the left side of the loines, diffuses a good portion thereof into the least part of the collicke gut, and the right gut, at the end whereof it is often seene to be divided into five Hæmorrhoidall veines, sometimes more, sometimes lesse.

Sylvius writes that the Hemorrhoidall branch descends from the mesentericks, and truly we have sometimes observed it to have beene so. Yet it is more sutable to reason, that it should descend from the splenicke, not onely for that we have seene with our eyes that it is so, but also because it is appointed by nature for the evacuation of the excrementitious melancholike humor. But this same splenick branch out of the middle almost of its upper part produces the third branch going to the gibbous part of the stomacke, and the kall; they terme it the greater, middle and left *Gastrepiplois*. But on the lower part towards the spleene it produces the simple *Epiplois*, or kall-veine, which it diffuses through the left side of the kall. Moreover from its upper part, which touches the liver, it sends forth a short branch called *vas breve*, or *venosum*, to the upper orifice of the ventricle for stirring up the appetite.

Wee have oftentimes and almost alwayes observed, that this veinie vessell, which *Galen* calls *vas breve*, comes from the very body of the spleene, and is terminated in the midst of the stomacke on the left side, but never peirces both the coates thereof. Wherefore it is somewhat difficult to find, how the melancholy juyce can that way be powred, or sent into the capacitie of the stomacke. Now the splenicke branch, when it hath produced out of it those five forementioned branches, is wasted and dispersed into the substance and body of the spleene:

Then followes another compound branch of the *vena porta*, called the mesentericke, which is divided into three parts; the first and least whereof goes to the blind gut, and to the right and middle part of the collicke-gut, divided into an infinite multitude of other branches. The second and middle is wasted in the *Ileon*; as the third and greater in the *Iejunum* or empty gut. It is called Mesentericke because it is diffused over all the Mesentery; as the splenicke is in the spleen. And thus much wee have to say of the division of the gate veine, the which if at any time thou shalt find to be otherwise, than I have set downe, you must not wonder at it; for you shall scarce finde it the same in two bodies, by reason of the infinite varietie of particular bodies, which (as the Philosophers say) have each their owne, or peculiar gifts. Our judgement is the same of other divisions of the vessels. Yet wee have set downe that which wee have most frequently observed.

CHAP. XXII.

*Of the originall of the Artery, and the division of the branch,
descending to the naturall parts.*

 Those things being thus finished and considered, the guts should be pulled away, but seeing that if we should do so, we should disturbe and loose the division of the artery descending to the naturall parts; therefore I have thought it better to handle the division thereof, before the guts be plucked away. Therefore we must suppose, according to *Galen's* opinion, that as all the veines come from the liver, so all arteries proceede from the heart. This presently at the beginning is divided into two branches, the greater whereof descends downwards to the naturall parts upon the spine of the backe, taking its beginning at the fifth *vertebra* thereof, from whence it goes into the following arteries. The first called the intercostall, runnes amongst the intercostall muscles, and the distances of the ribs, and spinall marrow, through the perforations of the nerves on the right and left hand from the fifth true, even to the last of the bastard ribs.

This in going this progresse makes 7. litle branchings, distributed after the forementioned manner, and going forth of the trunk of the descendant over against each of the intercostal Muscles.

The second being parted into two goes on each side to the midriffe, whence it may be called, or expressed by the name of the *Diaphragmatica* or *Phrenica* (i) the midriffe artery. The third being of a large proportion, arising from the upper part of the artery presently after it hath passed the midriffe, is divided into two notable branches, whereof one goes to the stomacke, spleene, kall, to the hollow part of the

liver and the gall; the other is sent forth to the mesentery and guts after the same manner, as wee said of the meseraicke veines, wherefore it is called the *Cæliaca*, or stomacke arterie. But wee must note, all their mouthes penetrate even to the innermost coate of the guts, that by that meanes they may the better and more easily attract the *Chylus* contained in them.

4. The fourth is carried to the reines, where it is named the reinall or emulgent, because it suckes fit matter from the whole masse of blood.

5. The fifth is sent to the testicles with the preparing spermaticke veines, whence also it is named the spermaticke artery, which arises on the right side, from the very trunk of the descendant artery; that it may associate the spermaticke veine of the same side, they runne one above another, beneath the hollow veine, wherefore wee must have a great care whilest wee labour to lay it open, that wee doe not hurt and breake it.

The sixth going from the fore and upper part of this descendant arterie, descends with the Hæmorrhoidall veines to the fundament; presently from his beginning, sending forth certaine branches alongst the collicke gut, which by *anastomosis* are united with other branches of the *Celiacall* arteries; for whosoever shall looke more attentively, he shall often observe that veines are so united amongst themselves, and also arteries, and sometimes also the veines with the arteries. For an *anastomosis* is a communion and communicating of the vessels amongst themselves, by the application of their mouthes, that so by mutuall supplies they may ease each others defects. But they call this the lower meseraicke arterie.

*Hæmorrhoidall
in sem mesenterice
interior.*

The seventh proceeding from the trunk with so many branches as there be *vertebra's* in the loines, goes to the loines and the parts belonging to them, that is, the spinall marrow of that part, and other parts encompassing these *Vertebra's*, whereupon it is stiled the *Lumbaris* or Loine Artery.

*vertebra's
Lumbaris.*

The eight maketh the Iliacke arteries, until such time as it departs from the *Peritonæum* where the Crurall Arteryes take their originall. This Iliacke Artery sends many divarications towards the Holy bone where it takes its beginning, and to the places lying nere the Holy bone, which because they run the same course as the Iliacke veins, for brevities sake, we will let passe further mention of them, till we come to treat of the Iliacke veines.

*Peritonæum
Iliaca.*

CHAP. XXIII.

Of the distribution of the Nerves to the naturall parts.

T remains, that before the bowels be taken away, we shew the nerves sent to the entrailes and naturall parts, that as wise and provident men we may seeme to have omitted nothing. First we must know that these nerves are of the sixth conjugation, which descend as well to the stomacke all alongst the Gullet and the sides thereof, as those at the roots of the ribbes on both sides within. But when they are passed through the Midriffe, those which are distributed amongst the naturall parts follow the turnings of the veines and arteryes, but specially of the arteryes. Wherefore if you have a mind to follow this distribution of the nerves, you must chiefly looke for it in those places, in which the artery is distributed amongst the Guts above the loynes.

*The originall
of the nerves
which are car-
ryed to the na-
turall parts.*

These nerves are but small, because the parts serving for nutrition, needed none but litle nerves, for the performance of the third duty of the nerves, which is in the discerning and knowing of what is troublesome to them. For unlesse they had this sense, there is nothing would hinder, but these bowels necessary for life, being possessed with some hurtfull thing, the creature should presently fall downe dead; but we have this benefit by this sense, that as soone as any thing troubles and vellicates the bowels, we being admonished thereof may looke for helpe in time.

*Their magni-
tude and use.*

And besides if they were destitute of this sense, they might be gnawne, ulcerated and putrified by the raging acrimony of the excrements falling into and staying in them; but now (by meanes hereof) as soone as they find themselves pricked, or pluckt, presently by the expulsive faculty they endeavour to expell that which is troublesome, and so free themselves of present and future dangers.

CHAP. XXIII.

The manner of taking out the Guts.

When the Guts are to be taken out, you must begin with the Right Gut. And you must divide it, being first straitly tyed in two different places, at a just distance about foure fingers from the end, with a sharp knife betweene the two ligatures. Then you must shew its proper coats, and fibers, and that common one which

which it hath from the *Peritoneum*. This being done, you must in like manner binde the truncke of the gate veine as neere the originall as you can; that so all his branches being in like manner tyed there may be no feare of effusion of blood: you must doe the like with the *Cæliacke Arterye* at the left kidney, and in the lower *Mesentericke*, which descends to the Right gut with the *Hæmorrhoidall* veines. This being done, pul away the guts even to the *Duodenum*, which being in like manner tyed in two places, which ought to be below the insertion of the *Porus Chologogus* or passage of the Gall, that you may shew the oblique insertion thereof into that gut; for the obliquity of its insertion is worth observation, as that which is the cause that the Gall cannot flow backe into its bladder, by the compression of this Gut from below upwards. Then all these windings of the Guts may be taken away from the body.

4.
Lumbaris

BEcause the rest of the naturall parts, do almost all depend upon the descendent Hollow veine, therefore before we goe any further, we will shew its originall and distribution. We said before that all veines proceeded from the Liver, but yet in divers places. For the gate veine goes out of the hollow part, and the Hollow veine out of the Gibbous part of the liver, which going forth like the body of a tree, is divided into two great branches, the lesser of which goes to the vitall and animall parts, and the extremities of these parts, as we shall shew in their place. The greater descending from the backe part of the Liver above the *Vertebra's* of the loines to the parts beneath, goes in the manner following. The first division thereof is to the membranes of the reines, which come from the *Peritoneum*. Wherefore there it produces the *Vene adiposa*, or fatty veines, so called because they bring forth a great quantity of fat in those places; Of these fatty veines, there is a diverse originall, for the right doth oftentimes arise from the right emulgent because it is higher; but the lesse comes from the very truncke of the hollow veine, because the emulgent on that side is lower, and you shall scarce see it happen otherwise.

The second being the Kidney or Emulgent veines, go to the Reines, Which at their entrance, or a little before, is divided into two branches, like as the Artery is, the one higher, the other lower; and these againe into many other through the substance of the Kidneys, as you may learne better by ocular inspection, than by booke. They are thick and broad that the serous humor may without impediment have free passage. Their originall is different, for the right Emulgent, often times comes forth of the Hollow veine somewhat higher than the left; that seeing their office and duty is to purge the masse of blood from the chollericke and serous humor, that if any part thereof slide by the one, it may not so scape, but fall as it were into the other. Which certainly would not have happened if they had bin placed the one just opposit to the other. For the Serous or wheyish humor would have stayed as equally ballanced or poised, by reason of the contrariety of the action and traction, or drawing therof. But we must remember that in dissecting of bodics, I have oft times found in such as have beene troubled with the stone, seven Emulgent veines and so many arteries; foure from the left side comming from diverse places, of which the last came from the Iliacke; three from the right hand likewise in diverse places.

The third division is called the *Spermaticke* or seed veine, it goes to the Testicles; the originall thereof is thus, that the right arises on the fore part of the trunck of the hollow veine; but the left most commonly from the emulgent. Besides you shall sometimes finde that these have companions with them, to the right emulgent; but to the left another from the hollow veine, in some but on one side, in others on both. But also I have sometimes observed the left emulgent to proceed from the *spermaticke* or seed veine.

The fourth because it goes to the loynes, is called *Lumbaris*; which in his originall and insertion is wholly like the Artery of the loines. But there are 4 *Lumbares* or Loine veines

veines on each side, that is, one in each of the 4 spaces of the 5 *Vertebras* of the loines.

The fift division makes the *Iliacæ*, until passing through the *Peritoneum*, they take the name of *Crurall* veines; These are first divided into the Musculous, so called, because they go to the oblique ascendent and transverse muscles, and to the *Peritoneum*. Sometimes they have their originall from the end of the Trunck. And then the same *Iliacæ* are divided into the *Sacra*, or holy, which goe to the spinall marrow of the Holy bone, through those holes, by which the nerves generated of this marrow, have their passage.

Thirdly the *Iliacæ* are divided into the *Hypogastrica* so called, because they are distributed to all the parts of the *Hypogastrium*, or lower part of the lower belly, as to the right Gut, the muscles therof, the musculous skin, (in which place they often make the externall *Hæmorrhoidall*, ordained for the purging of such blood as offends in quantity, as those other [that is, the inward *Hæmorrhoidall*] which descend to the right Gut from the Gate veine by the spleenicke branch, serves for cleansing of that which offends in qualitie) to the bladder and the necke thereof even to the end of the yard, to the wombe, and even to the necke of the wombe and uterine parts of the privities; from whence it is likely the courses breake forth in weomen with child and virgins. But this same veine also sends a portion of it without the *Epigastrium* by that perforation which is common to the share and haunch bones, which strengthened by meeting of the other internall *Crurall* veine descends even to the Hamme, but in the meane time by the way it is communicated to the muscles of the thigh called *Obstratores* and other parts within. Fourthly, the *Iliacæ* produce the *Epigastrica* which on both sides from below ascend according to the length of the right muscles, spreading also by the way some branches to the oblique and transverse muscles and also to the *Peritoneum*. Fifthly, these *Iliacæ* produce the *Pudenda* or veines of the privities because they go in women to their privities, and into men to the Cods, where they enter that fleshy coat filled with veines, and goe to the skin of the yeard, they take there beginning under the *Hypogastrica*.

CHAP. XXVI.

Of the Kidneyes or Reines.

Now follow the Kidneyes, which that they may bee more easily scene, (after that you have diligently observed their scituation) you shall dispoile of there far, if they have any about them, as also of the membrane they have from the *Peritoneum*. First you shall shew all their conditions, beginning at their substance.

The substance of the Kidneyes is fleshy, dense and solid, least they should be hurt by the sharpnes of the urine; Their magnitude is large enough, as you may see. Their figure is somewhat long and round almost resembling a semicircle, and they are lightly flatted above and below. They are partly hollow and partly gibbous; the hollow lyes next the hollow veine, and on this side they receive the emulgent veines and Arteryes, and send forth the ureters; there gibbous part lyes towards the loines. They are composed of a coate comming from the *Peritoneum*, their owne peculiar flesh, with the effusion of blood about the proper vessels (as happens also in other entrails) generates a small nerve, which springing from the Costall of the sixt conjugation is diffused to each Kidney on his side into the coat of the kidney it selfe, although others thinke it alwayes accompanies the veine and artery.

But *Fallopins* that most diligent Author of Anatomy hath observed, that this nerve is not only oftentimes divaricated into the coat of the kidneyes, but also pierces into their substance. They are two in number that if the one of them should by chance be hurt, the other might supply those necessities of nature, for which the Kidneyes are made. They lye vpon the loynes at the sides of the great vessels, on which they depend by their proper veines and arteries; and they sticke to them, as it were by a certaine second coate, lest that they might be shaken by any violent motions. Wherefore

Their substance,

Their Strainer.

fore we may say that the Kidneyes have two coates, one proper adhering to their substance, the other as it were coming from the *Peritoneum* on that part they sticke to it. The right Kidney is almost alwayes the higher, for those reasons I gave, speaking of the originall of the Emulgent vessels. *Columbus* seemes to thinke the contrary, but such like controversies may be quickly decided by the Eye. They have connexion with the principall vessels by the veines, nerves and arteries, by the coates with the loines and the other parts of the lower belly, but especially with the bladder by the ureters. They are of a hot and moist temper, as all fleshy parts are. Their action is to cleanse the Masse of the blood from the greater part of the serous and cholericke humor. I said the greater part, because it is needfull that some portion thereof should go with the alimentary blood to the solid parts, to serve in stead of a vehicle lest otherwise it should be too thicke.

Besides you must note that in each kidney there is a cavitye bounded by a certaine membrane, incompassed by the division of the emulgent veines and arteryes, through which the urine is strained partly by the expulsive facultie of the kidneyes, partly by the attractive of the ureters, which run through the substance of the kidneyes on the hollow side, no otherwise than the *Porus cholagogus* through the body of the Liver.

CHAP. XXVII.

Of the Spermaticke Vessells.

Now we should have spoken of the ureters, because as wee sayd before, they are passages derived from the Kidneyes to carry the urine to the bladder. But because they cannot be distinguished and shewed unles by the corrupting and vitiating the site of the spermaticke vessels; therefore I have thought it better to passe to the explication of all the spermaticke parts.

And first of all you must gently separate them, (that so the declaration of them may be more easie & manifest) and that from the coat which comes from the *peritoneum*, and the fat which invests them even to the share-bone, having diligently considered their site before you separate them. Then you shall teach that the substance of these vessels, is like to that of the veines and arteryes. Their quantity is small in thicknes, but of an indifferent length, by reason of the distance of their originall from the Testicles. They are longer in men than in weomen, because these have their Testicles hanging without their belly, but weomen have them lying hid within their belly. Their figure and composure is wholly like the figure and composition of the veines and arteries, except in this one thing, that from that place where they goe forth of the great capacity of the *Peritoneum*, they are turned into many intricate windings, like crooked swolne veines, even to the Testicles. That the spermaticke matter in that one tracte, which yet is no other than blood, may be prepared to concoction, or rather be turned into seed in these vessells, by the irradiation of the faculty of the Testicles. These vessells are sixe in number, foure preparing, and two ejaculatory, of which we will speake hereafter. Therefore on each side there be two preparing vessels, that is, a veine and an artery, arising as we told you when we spoke of the distribution of the hollow veine. They are inserted into the Testicles through that coate which some call *Epididymis*, others *Dartos*. Their site is oblique above the loines and flanks, whilest they runne downe betweene the ends of the share and hanch bone, they are knit to the parts lying under them, both by certaine fibers which they send from them, as also by the membrane they have from the *Peritoneum*. They have like temperature as the veines and Arteries have. Their action is to carry blood to the Testicles, for generating of seed.

CHAP. XXVIII.

Of the Testicles, or Stones.

The Testicles are of a Glandulous, white, soft and loose substance, that so they may the more easily receive the spermaticke matter: their magnitude and figure equall, and resemble a small pullets Egge somewhat flatted; Their composure is of veines, arteries, coats and their proper flesh. Their veines and arteries proceed from the spermaticke vessels, their nerves from the sixth conjugation, by the roots of the ribbes and out of the holy bone. They are wrapped in foure coats, two whereof are common, and two proper. The common are the *Scrotum* or skin of the Cods, proceeding from the true skin; and the fleshy coate, which consists of the fleshy Pannicle in that place receiving a great number of vessells, through which occasion it is so called. The proper coats are first the *Erythron* arising from the proesse of the *Peritoneum*, going into the *Scrotum* together with the spermaticke vessels which it involves and covers; this appeares red both by reason of the vessells as also of the *Cremaster* muscles of the Testicles; Then the *Epididymis* or *Dartos* which takes its originall of the membrane

of the spermatick preparing vessels. The flesh of the Testicles is as it were a certaine effusion of matter about the vessels, as we said of other entrails. But you must observe that the *Erythroides* encompasses the whole stone, except its head, in which place it sticks to the *Epididymis* which is continued through the whole substance of the Testicle. This *Epididymis* or *Dartos* was therefore put about the stones, because the Testicles of themselves, are loose, spongy, cavernous and soft, so that they cannot safely be joyned to the spermatick vessels which are hard and strong. Wherefore Nature that it might joine extremes by a fit *Medium*, or meane, formed this coate *Epididymis*. This is scarce apparent in weomen by reason of its smallnesse. The two fore-mentioned common coats, adhere or sticke together by their vessels not only amongst themselves, but also with the *Erythroides*. You must besides observe the *Cremaster* muscles are of the said substance with other muscles, small and thin, of an oblique and broad figure, arising from the membrane of the *Peritoneum*, which (as we said before) assumes flesh from the flanks. Their composition is like that of other muscles. They are two, one each side on. They are situate from the ends of the flanks, even to the stones. They have connexion with the procelle of the *Peritoneum* and Testicles. Their temper is like that of other muscles. Their action is to hang and draw up the Testicles towards the belly, whence they are called, hanging muscles. The Testicles are most commonly two in number, on each side one, sometimes there be three, sometimes one alone, as it happens also in the Kidneies; for some have but one Kidney. They lye hid in the *Scrotum* at the very roots of the share bone, connexed to the principall parts of their vessels, with the necke of the bladder and yard; but by their coats they adhere to the parts from whence they have them. They are of a cold and moist temper, because they are glandulous; although they may be hot by accident by reason of the multitude of the vessels flowing thither. Those whose testicles are more hot are prompt to venery, and have their privities and the adjacent parts very hairy, and besides their testicles are more large and compact. Those on the contrary that have them cold are slow to venery, neither doe they beget many children, and those they get are rather female than male, their privities have litle haire upon them, and their testicles are small, soft and flat.

The action of the testicles is to generate seed, to corroborate all the parts of the body, and by a certaine manly irradiation to breed or encrease a true masculine courage. This you may know by Eunuches or such as are Gell, who are of a womanish nature, and are oftentimes more tender and weak than weomen. As *Hippocrates*, teaches by the example of the Scythians, *lib. de Aere, locis et aquis*.

CHAP. XXIX.

Of the varicous bodyes or *Parastrata*'s, and of the ejaculatory vessels and the glandulous or Prostates.

Their substance.

Here the Author speaks otherwise then *Galen*.

Action.

The varicous *Parastrata* are nervous and white bodyes, like as the nerves; round and close woven amongst themselves, they are stretched even from the top to the bottome of the testicles, from whence presently by their departure they produce the *Vasa ejaculatoria*, or trading vessels. But unless we doe very well distinguish their names, wee shall scarce shun confusion. For that which I call *Parastrata*, that is, as it were the head of the testicle, being as it were like another stone, is called *Epididymis* by *Galen lib. i. de semine*. But I by the example and authority of many Anatomists, understand by the *Epididymis* the proper coate of the testicles, of which thing I thought good by the way to admonish you of. Their Action is by their crooked passages to hinder the seed from departing out of the preparing into the leading vessels, before it shall be most perfectly laboured and concocted in these vessels by the power and force of the testicles. For in the first windings, the blood looks pure; but in the last it is not so red, but somewhat whitish. For Nature commonly doth thus delay the matter in its passage either by straitnesse, or obliquity, which it desires to make more perfect and elaborate by any new

new concoction; this we may learne by the foldings of the *Rete mirable*, the windings of the Guts, the wrinckles in the bottome of the stomacke, the straitnesse of the *Pylorus*, the capillary veines disperfed through the body of the Liver; certainly nature hath intended some such thing in the making of the spermaticke vessels. Their quantity is visible, and figure round tending somewhat to sharpnesse. They are composed of veines, nerves and arteryes (which they enjoy from the vessels of the testicles, from the *Epididymis*, or the coat, from the *Peritoneum* and their proper substance. Their temper is cold and dry. They be two in number, one to each testicle. But these varicous bodyes are called *Parastata*, Assisters, because they superficially assist, and are knit to the testicles according to their length, or long-ways. Out of the *Parastata* proceed the *Vasa ejaculatoria*, or leading vessels, being of the same substance as their progenitors, that is, solid, white and as it were nervous. Their quantity is indifferent, their figure round, and hollow, that the seed may have a free passage through them, yet they seeme not to be perforated by any manifest passage, unlesse by chance in such as have had a long *Gonorrhoea*. They have like temper as the *Parastats*, betweene which and the Prostates they are seated, immediatly knit with them both; as both in the coat and the other vessels with the parts from whence they take them.

Their quantity, figure and composition.

Their temper and number.

Vasa ejaculatoria the ejaculatory or leading vessels.

But we must note, that such like vessels coming out of the *parastats* ascend from the botom of the stones even to the top, in which place meeting with the preparing vessels, they rise into the belly by the same passages, and bind themselves together by nervous fibers, even to the inner capacity of the belly; from whence turning backe, they forsake the preparing, that so they may run to the bottome of the share-bone, into the midst of two glandulous bodies which they call *prostats* scituate at the neck of the bladder, that there meeting together they may grow into one passage.

For thus of three passages, that is, of the 2 leading vessels and 1 passage of the bladder, there is one common one in men for the casting forth of seed and urine. A Caruncle rising like a crest at the beginning of the neck of the bladder argues this uniting of the passages, which receiving this same passage which is sufficiently large, is oft times taken by such as are ignorant in anatomy for an unnaturall Caruncle, then especially when it is swolne through any occasion. These leading vessels are two in number, on each side one. Their action is to convey the seed made by the testicles to the Prostats and so to the necke of the bladder, so to be cast forth at the common passage. But if any aske whether that common passage made by the two leading vessels betweene the two glandulous bodyes be obvious to sense or no? We answer it is not manifest, though reason compell us to confesse that that way is perforated by reason of the spermaticke, grosse and viscous matter carryed that way. But peradventure the reason why that passage cannot be seene is, because in a dead carcassee all small passages are closed and hid, the heat and spirits being gone, and the great appeare much lesse, by reason all the perforations fade, and fall into themselves. Yet certainly these passage must needs be very strait, even in a living man, seeing that in a dead they will not admit the point of a needle. Wherefore we need not feare, least in searching, whilst we thrust the *Catheter* into the bladder, it penetrate into the common passage of the leading vessels which runnes within the Caruncle, unlesse peradventure by some chance, as a *Gonorrhoea*, or some great *Phlegmon*, it be much dilated besides nature. For I have sometimes seene such passages so open, that they would receive the head of a Spatherne; which thing should admonish us, that in searching we take great care, that we doe not rashly hurt this Caruncle, for being somewhat rashly handled with a *Catheter* it casts forth blood, especially if it be inflamed. But also the concurrence of the spirits flowing with great violence together with the seed, much helps forward such ejaculation thereof performed through these strait passages by the power of the imaginative faculty in the Act of generation.

Their number and action.

This Caruncle must be observed and distinguished from a *Hyper-sarcosis* or fleshy excrescence.

After the leading vessels follow the *Prostata*, being glandulous bodyes of the same substance and temper that other Glandules are. Their quantity is large enough, their figure round, and somewhat long, sending forth on each side a soft production of an indifferent length. They are composed of veines, nerves, arteries, a coate (which they have from the neighbouring parts) and lastly their proper flesh, which they have

morbo.

from their first conformation. They are two in number, scituate at the roote of the necke of the bladder, somewhat straitly bound, or tyed to the same, to the leading vessels, and the parts annexed to them. But alwaies observe, that every part which enjoyes nourishment, life and sense, either first or last hath connexion with the principall parts of the body, by the intercourse of the vessels which they receive from thence.

The use of the Prostats is, to receive in their proper body the seed laboured in the testicles, and to containe it there, untill it be troublesome either in quantity or quality or both. Besides they containe a certaine oily and viscide humor in their glandulous body, that continually distilling into the passage of the urine, it may preserve it from the acrimony and sharpnesse thereof. But wee have observed also on each side other Glandules, which *Rondeletius* calls *Appendices glandulose*, Glandulous dependances to arise from these Prostats, in which also their is seed reserved.

CHAP. XXX.

Of the Vreters.

Now it seemes fit to speak of the Vreters, bladder, and parts belonging to the bladder. Therefore the Vreters are of a spermaticke, white, dense and solid substance, of an indifferent bignes in length and thickness. Their figure is round and hollow. They are composed of two coats, one proper consisting of right and transverse fibers, which

The substance
magnitude
figure and
composure of
the vreters,

comes from the emulgent veines and arteries; the other common from the *Peritoneum*; besides they have veines, nerves and arteryes from the Neighbouring parts.

They be two in number on each side one; They are scituate between the Kidneyes (out of whose hollow part they proceed) and the bladder. But the manner how the Vreters insert or enter themselves into the bladder, and the *Porus Cholagogus* into the *Duodenum*, exceeds admiration; for the ureters are not directly but obliquely implanted neere the orifice of the bladder & penetrate into the inner space thereof; for within they doe as it were divide the membrane or membranous coat of the body of the bladder, and insinuate themselves into that, as though it were double. But this is opened at the entrance of the urine, but shut at other times, the cover as it were falling upon it, so that the humor which is false into the capacity of the bladder cannot bee forced or driven backe, no not so much as the aire blowne into it can come this way out, as we see in swines bladders blowne vp and filled with aire.

Number and
size,

For wee see it is the Aire contained in these which fills them thus, neither canne it bee pressed forth but with extraordinary force.

For as this skinne or coat turned in by the force of the humor giues way, so it being pressed out by the body contained within, thrusts its whole body into the passage as a stopple; like to this is the insertion of the *Porus Cholagogus* into the Guts.

The ureters have connexion with the above mentioned parts, with the muscles *Connexion* of the loines; upon which they runne from the Kidneyes to the bladder.

Wherefore nothing hinders, but that the stone sliding through the ureters into the bladder, may stupify the thigh as much as it did when it was in the Kidney. They are of a cold and dry temper.

Their use is, to serve as passages, or channels for carrying the urine into the bladder. *Temper and use,*

CHAP. XXXI.

Of the Bladder.

The bladder is of the same substance that the ureters, that is, nervous, that *The substance* so it may bee the more easily dilated.

It is of a large proportion, in some bigger in some lesse, according to the difference of age, and habite of body. It is of a round figure and as *Figure.*

it were Pyramidall.

It is composed of two coats, one proper which is very thicke and strong composed of the three sorts of fibers, that is, in the inner side of the direct; without of the transverse; and in the midst of the oblique. *Composition,*

The other common Coat comming from the *Peritoneum* hath veines and arteryes on each side one, from the *Hypogastrick* vessels above the holy-bone, also it hath nerves on each side from the sixth conjugation mixt with the nerves of the holy-bone.

For these nerves descend from the braine even to the end of the holy-bone.

It is but one and that scituate in men in the lower belly upon the right Gut and below the share bone, but in women between the wombe and that bone, to which it cleaves with its membranous ligaments, as it doth to the yard by its neck, and to the

Temper, use or
action.

the right gut by its common coate and proper vessels. It is of a cold and dry temper.

Temper, use or
action.

The use and action thereof is by the fibers continually to draw the urine, and containe it as long as neede requires, and then to expell it by the necke, partly by compression either of it selfe, or rather of the muscles of the *Epigastrium* and *Midriffe*, because this motion, seeing it is voluntary cannot be performed unlesse by a muscle which the bladder wants; partly also by the dilatation and relaxation of the sphincter muscle composed of transverse fibers, like the sphincter of the fundament, after the same manner to shut up the orifice of the bladder, that the urine flow not out against our will. But the bladder as it fills is dilated, but as it is emptied, it is contracted like a purse. You may easily observe this Muscle in a Sowes bladder, it is stretched from the orifice of the bladder and beginning of the urinarye passage even to the privities even in women; but in men it is terminated in the *Perinaum*, as soone as it hath left the right Gut.

Besides, this muscle is thus farre stretched forth, that the urine by its compression should be wholly pressed out of the bladder, which by too long stay would by its acrimony doe some harme. This is the common opinion of Anatomists concerning the Sphincter of the bladder, which never-the-lesse *Fallopins* allowes not of. For (saith hee) if this muscle should bee scituate beneath the glandulous bodies, the seed in copulation could never be cast forth without some small quantity of urine. Wherefore he thinks that this muscle is scituate above the *Prostata*, and that it is nothing els but the beginning of the necke of the bladder, which becoms more fleshy whilst it is woven with transverse fibers.

The eleventh figure of the bladder and yarde.

AB, 1, 2, 3, 4, 5, 7, 9. The two bodies which make the yarde.

CC 2, 3. The place where these two bodies do first arise.

D 1, 2, 4, 5, 7, 9. The nut of the yarde called *glans penis*.

EE 4, 5. The fungous and redde substance of the bodies of the yarde.

F 4, 5. The mutuall connexion of the bodies of the yarde, and the nervous outward substance of the same, compassing round about the former fungous substance.

G 1, 2, 3, 4, 5, 7, 9. The passage of the urine, or common pipe running under the yarde all along his length.

H. I. 1, 2. The first paire of Muscles of the yarde,

which in the first figure doe yet grow to it, but in the second they hang from their originall. K. L. 1, 2. The second paire of Muscles of the yarde, in the first figure growing, in the second hanging from their insertion. M 1, 2. The sphincter of the right gut. N 3, 7, 8, 9. The round sphincter Muscle of the bladder. O O, A Membrane which

which is over the holes of the share bone. P 2. A rounde Ligament from the meeting of the share bones unto the head of the thigh. Q. 3, 7, 8. The body of the bladder. R R, 3, 7. The *Prostate*, into which seed when it is perfectly laboured, is led. S S, 3, 8. Portions of the ureters. T T* 3, Portions of the vessels which leade downe the seed. V V, 7, 8. The umbilicall arteries. X 7, 8. The ligament of the bladder cald *Vrachus*. Y, 7, 8. The navel or *umbilicus*. Z, 7, 8. The umbilicall veine. aa 7. The veine and artery of the yard. b 5. The artery distributed through the body of the yard.

For the necke of the bladder it differs nothing in substance, compofure, number, and temper from the bladder, but onely in quantity, which is neither so large, nor round in figure, but somewhat long together with the yarde representing the shape of the letter S. It is placed in men at the end of the right Gut and *Perinaum*, rising upwards even to the roots of the yarde, and with it bending it self downwards; in weomen it is short, broad, and streight, ending at the orifice of the necke of the wombe betweene the nervous bodyes of the *Nympha*.

The necke of the bladder.

In men it hath connexion with the bladder, the ejaculatory vessels, the right gut and yarde; but in weomen onely with the necke of the wombe and privities. The use of it is in men to cast forth seed and urine, in weomen onely urine. But wee must note that the share bones must be divided and pulled asunder, in that part where they are joyned, that so you may the more exactly observe the scituation of these parts. Besides you must note that by the *Perinaum* we understand nothing else, in men and weomen, than that space which is from the fundament to the privities in which the seame is called *Tanyus*.

The connexion or use thereof.

CHAP. XXXII.

Of the yarde.

OW followes the declaration of the Privy parts of men and weomen, and first wee will treat of mens. The yard is of a ligamentous substance because it hath its originall from bones, it is of an indifferēt magnitude in all dimenſions, yet in ſome bigger, in ſome leſſe; the figure of it is round, but yet ſome what flattened above and beneath.

The ſubſtance quantity and figure of the yarde.

It is compoſed of a double coat, Nerves, veines, arteryes, two ligaments, the paſſage of the urine, and foure muſcles. It hath its coats both from the true ſkin; as alſo from the fleſhy pannicle, but the veines and Arteryes from theſe of the lower part of the lower belly which runne on the lower part of the Holy-bone into the yard, as the ſeminary veſſels runne on the upper part.

Compoſure.

The ligaments of the yard proceed on both ſides from the ſides and lower commiſſure of the ſhare-bones; wherefore the yard is immediatly at his root furniſhed with a double ligament, but theſe two preſently runne into one ſpongy one. The paſſage of the urine ſituate in the lower part of the yarde comes from the neck of the bladder betweene the two ligaments.

The ligaments.

For the foure muſcles, the two ſide ones compoſeing or making a great part of the yard, proceed from the inward extuberancy of the Hip-bone, and preſently they are dilated from their originall, and then grow leſſe againe. The two other lower ariſe from the muſcles of the fundament and accompany the urinary paſſage the length of the *perinaum* untill they enter the yard; but theſe two muſcles cleave ſo cloſe together, that they may ſeeme one having a triangular forme.

The muſcles.

The action of theſe foure muſcles in the act of generation is they open and dilate this common paſſage of urine and ſeed, that the ſeede may be forcibly or violently caſt into the ſeild of nature; and beſides they then keepe the yarde ſo ſtiſſe, that it cannot bend to either ſide.

Their Action.

The yard is in number one, and ſituate upon the lower parts of the ſhare bone that it might

might bee more stiffe in erection. It hath connexion with the share-bone and neighbouring parts; by the particles of which it is composed. It is of a cold and dry temper. The action of it is to cast the seed into the wombe, for preservation of mankind.

The Nut,
The *Præputium*,
or foreskin.

The head of it begins where the tendons end, this head from the figure thereof is called *Glans* and *Balanus*, that is the Nut, and the skin which covers that head is called *Præputium* that is, the foreskin. The flesh of this *Glandule* is of a middle nature between the Glandulous flesh and true skin. But you must note that the Ligaments of the yarde are spongy contrary to the condition of others, and filled with grosse and blacke blood. But all these stirred up by the delight of desired pleasure and provoked with a venereall fire, swell up and erect the yard.

CHAP. XXXIII.

Of the spermaticke vessels and testicles in weomen.

In what the
spermaticke
vessels in weo-
men differ
from those in
men.

OW we should treat of the Privy parts in weomen but because they depend upon the necke and proper body of the wombe, we will first speake of the wombe, hauing first declared what difference there is betweene the spermaticke vessels and testicles of men and weomen. Wherefore we must know that the spermatick vessels in weomen do nothing differ from those in men in substance, figure, composure, number, connexion, temper, originall and use, but only in magnitude and distribution; for weomen have them more large and short.

Why they are
larger but
shorter then
mens.

It was fit they should be more large, because they should not onely convey the matter fit for generation of young and nourishment of the testicles, but also sufficient for the nourishment of the wombe and child; but shorter because they end at the testicles and wombe within the belly in weomen. Where you must note that the preparing spermaticke vessels, a litle before they come to the Testicles, are divided into two unequall branches, of which the lesser bended, after the same manner as wee said in men, goes into the head of the testicle, through which it sends a slender branch into the coats of the testicles for life and nourishment, and not onely into the coats but also into the leading vessels. But the bigger branch descends on each side by the upper part of the wombe betweene the proper coate and the common, from the *Peritoneum* where it is devided into diuers branches. By this difference of the spermaticke vessels you may easily understand why weomen cast forth lesse seed than men.

In what their
testicles differ
from mens.

For their Testicles, they differ litle from mens but in quantity; For they are lesser and in figure more hollow and flat, by reason of their defective heat which could not elevate or lift them vp to their just magnitude. Their composure is more simple, for they want the *scrotum* or cod, the fleshy coate, and also according to the opinion of some the *Erythroides*, but in place thereof they have another from the *Peritoneum* which covers the proper coat, that is the *Epididymis*, or *Dartos*. *Silvius* writes that womens Testicles want the *Erythroides*; yet it is certaine that besides their peculiar coat *Dartos*, they have another from the *peritoneum*, which is the *Erythroides*, or as *Fallopins* calls it the *Elythroides*, that is as much as the *vaginalis* or sheath. But I thinke that this error hath sprung from the misunderstanding that place in *Galen* where he writes, that womens testicles want the *Epididymis*. For we must not understand that to be spoken of the coate, but of the varicous parastrats (as I formerly said). They differ nothing in number, but in site; for in men they hang without the belly at the share bone above the *Peritoneum*; weomen have them lying hide in their belly, nere the bottome at the sides of the wombe, but yet so as they touch not the body of the wombe.

Lib. 14. de usu
part.

Site.

Connexion.

But these testicles are tyed to the wombe both by a coate from the *Peritoneum*, as also by the leading vessels descending to the hornes of the wombe, but to the rest of the body by the vessels and the nerves arising from the holy bone and

Costall

costall nerves. They are of a colder Temper than mans. The ejacutorie, or leading vessels in women differ thus from mens, they are large at the beginning, and of a veinie consistence, or substance, so that you can scarce discern them from the coate *Peritonæum*, then presently they become nervous, and waxe so slender, that they may seeme broken or torne, though it be not so; but when they come nearer to the hornes of the wombe, they are againe dilated; in their other conditions, they agree with mens, but that they are altogether more slender and short. They have a round figure, but more intricate windings than mens; I beleeeve, that these windings might supply the defect of the varicous Parastats. They are seated betweene the testicles and wombe, for they proceede out of the head of the testicle, than presently armed with a coate from the *Peritonæum*, they are implanted into the wombe by its hornes.

CHAP. XX XIII.

Of the Wombe.

Wherein the
privy parts in
women differ
from those in
men.

The Wombe is a part proper onely to women, given by nature in stead of the *Scrotum*, as the necke thereof, and the annexed parts in stead of the yard; so that if any more exactly consider the parts of generation in women and men, he shall finde that they differ not much in number, but onely in situation and use. For that which man hath apparent without, that women have hid within, both by the singular providence of Nature, as also by the defect of heate in women, which could not drive and thrust forth those parts, as in men. The wombe is of a nervous and membranous substance, that it may be more easily dilated and contracted, as neede shall require.

The substance
and magni-
tude of the
wombe.

The magnitude thereof is diverse, according to the diversitie of age, the use of venery, the flowing of their courses, and the time of conception. The wombe is but small in one of unripe age, having not used venery, nor which is menstruous; therefore the quantitie cannot be rightly defined.

Figure.

The hornes of
the wombe.

Composure.
The veins and
Arteries.

The figure of the wombe is absolutely like that of the bladder, if you consider it without the productions, which *Herophilus* called hornes, by reason of the similitude they have with the hornes of Oxen at their first coming forth. It consists of simple and compound parts. The simple are the veines, arteries, nerves, and coates. The veines and arteries are foure in number, two from the preparing spermaticke vessels, the two other ascend thither from the *Hypogastricke*, after this manner.

First, these vessels before they ascend on each side to the wombe, divide themselves into two branches, from which other some goe to the lower part of the wombe, other some to the necke thereof, by which the menstruous bloud, if it abound from the conception, may be purged.

Nerves.

Nerves come on both sides to the wombe, both from the sixt conjugation, descending by the length of the backe bone, as also from the holy bone, which presently united and joyned together, ascend and are distributed through the wombe, like the veines and arteries.

The Coats.

The utmost or common coate of the wombe, proceeds from the *Peritoneum*, on that part it touches the holy bone; but the proper it hath from the first conformation, which is composed of the three sorts of fibers, of the right on the inside for the attraction of both seedes; the transverse without to expell, if occasion be; the oblique in the midst for the due retention thereof.

The

The wombe admits no division, unlessse into the right and left side, by an obicure line or seame, such as we see in the *Scrotum*, but scarce so manifest; neither must we ascertthe maner of the ancients, or imagine any other icels in the womb. For by the law of nature, a woman at one birth can have no more than two. An argument hereof is, they have no more than two dugges. If any chance to bring forth more, it is besides nature, and somewhat monstrous, because nature hath made no provision of nourishment for them.

No cels in the wombe.

Nature hath placed the wombe at the bottome of the belly, because that place seemes most fit to receive seede, to carrie and bring forth the young. It is placed betweene the bladder and right gut, and is bound to these parts much more straitly, by the necke, than by the body thereof; but also besides it is tied with two most strong ligaments on the sides, and upper parts of the sharebone, on which it seemes to hang; but by its common coate from the *Peritoneum*, chiefly thicke in that place, it is tied to the hollow bone, and the bones of the hanch and loines.

The site.

By reason of this strait connexion, a woman with child feeling the painefull drawings backe, and as it were, convulsions of those ligaments, knowes her selfe with child. It is of a cold and moist temper, rather by accident, than of it selfe. The action thereof is to containe both the feedes, and to chearish, preserve, and nourish it, so contained, untill the time appointed by nature; and also besides, to receive, and evacuate the menstruous blood. The compound parts of the wombe are, the proper body and necke thereof. That body is extended in women bigge with child, even to the navell, in some higher, in some lower.

The temper and action.

In the inner side the *Cotyledones* come into our consideration, which are nothing else than the orifices and mouthes of the veines, ending in that place. They scarce appeare in women, unlessse presently after child-bearing, or their menstruall purgation; but they are apparent in sheepe, Goates, and Kine, at all times like wheat cornes, unlessse when they are with young, for then they are of the bignesse of hasell nuts; but then also they swell up in women, and are like a rude piece of flesh of a finger and a halfe thicke; which begirt all the naturall parts of the infant shut up in the wombe; out of which respect this shapelesse flesh, according to the opinion of some, is reckoned amongst the number of coates investing the infant, and called *Chorion*, because, as in beasts, the *Chorion* is interwoven with veines, and arteries, whence the umbilicall vessels proceede; so in women this fleshie lumpe is woven with veines, and arteries, whence such vessels have their originall. Which thing, how true and agreeable to reason it is, let other men judge.

The *Cotyledones*.

Columbus justly reproved.

There is one thing whereof I would admonish thee, that as the growth of the *Cotyledones* in beasts, are not called by the name of *Chorion*, but are onely said to be the dependants thereof, so in women such swollen *Cotyledones* merit not the name of *Chorion*, but rather of the dependances thereof,

This body ends in a certaine straitnesse which is met withall, in following it towards the privities, in women who have borne no children, or have remained barren some certaine time; for in such as are lately delivered, you can see nothing but a cavitie and no straitnesse at all. This straitnesse wee call the proper orifice of the wombe, which is most exactly shut after the conception, especially untill the membrane, or coats incompassing the child be finished, and strong enough to containe the seede, that it flow not forth, nor be corrupted by entrance of the aire; for it is opened to send forth the seede, and in some the courses and serous humors, which are heaped up in the wombe in the time of their being with child.

The orifice of the wombe.

The proper orifice of the wombe is not alwayes exactly shut in women with child.

The necke of the wombe.

From this orifice the necke of the wombe taking its originall, is extended even to the privities. It is of a musculous substance, composed of soft flesh, because it might be extended and contracted, wrinkled, and stretched forth, and unfolded, and wrested, and shaken at the comming forth of the child, and after be restored to its former soundnesse and integritie. In proceesse of age it growes harder, both by use of venery, and also by reason of age, by which the whole body in all parts thereof becomes drie and hard. But in growing, and young women, it is more tractable and flexible for the necessitie of nature.

The

Its magnitude.
Composition,

The magnitude is sufficiently large in all dimensions, though divers, by reason of the infinite varietie of bodies. The figure is long, round, and hollow. The composition is the same with the wombe, but it receives not so many vessels as the wombe; for it hath none but those which are sent from the *Hypogastricke* veines, by the branches ascending to the wombe. This necke on the inside is wrinckled with many crests, like the upper part of a dogges mouth, so in copulation to cause greater pleasure by that inequality, and also to shorten the act.

Number and
size,

It is onely one, and that situate betweene the necke of the bladder and the right gut, to which it closely sticketh, as to the wombe by the proper orifice thereof, and to the privities by its owne orifice; but by the vessels to all the parts from whence they are sent.

Temper.

It is of a cold and drie temper, and the way to admit the seede into the wombe, to exclude the infant out of the wombe, as also the menstruali evacuation. But it is worth observation, that in all this passage there is no such membrane found, as that they called *Hymen*, which they feigned to be broken at the first coition. Yet notwithstanding *Columbus*, *Fallopins*, *Wierus*, and many other learned men of our time think otherwise, and say, that in Virgins a litle above the passage of the urine, may be found and seene such a nervous membrane, placed overthwart as it were in the middle way of this necke, and perforated for the passage of the courses. But you may finde this false by experience; it is likely the Ancients fell into this error through this occasion, because that in some a good quantitie of blood breakes forth of these places at the first copulation.

No Hymen.

From whence
the blood pro-
ceeds that
breaks forth
in some vir-
gins in the
first coition,

But it is more probable, that this happens by the violent attrition of certaine vessels lying in the inward superficies of the necke of the wombe, not being able to endure without breaking so great extention as that nervous necke undergoes at the first coition. For a maide which is marriageable, and hath her genitall parts proportionable in quantitie and bignesse to a mans, shall finde no such effusion of blood, as we shall shew more at large in our Booke of Generation.

This necke ends at the privities, where its proper orifice is, which privy parts we must treat of, as being the productions and appendices of this necke. This *Pudendum*, or privitie, is of a middle substance, betweene the flesh and a nerve; the magnitude is sufficiently large, the figure round, hollow, long. It is composed of veines, arteries, nerves, descending to the necke of the wombe, and a double coate proceeding from the true skinn and fleshie pannicle; both these coates are there firmly united by the flesh comming betweene them; whereupon it is said, that this part consists of a musculous coate. It is one in number, situate above the *Perinaum*. It hath connexion with the fundament, the necke of the wombe and bladder by both their peculiar orifices.

It hath a middle temper, betweene hot, and cold, moist and drie. It hath the same use as a mans *Preputium* or fore-skinne, that is, that together with the *Nympha* it may hinder the entrance of the aire, by which the wombe may be in danger to take cold.

Ala.

αλειον, αλματα.

The lips of the privities called by the Greekes αλειον, αλματα, by the Latines *Ala*, containe all that region which is invested with haire; and because we have false into mention of these *Nympha*, you must know that they are as it were productions of the musculous skinn, which descend on both sides, from the upper part of the share-bone downwards, even to the orifice of the necke of the bladder, oft times growing to so great a bignesse, that they will stand out like a mans yard. Wherefore in some they must be cut off in their young yeares, yet with a great deale of caution, lest if they be cut too rashly, so great an effusion of blood may follow, that it may cause, either death to the woman, or barrenesse of the wombe by reason of the refrigeration by the too great effusion of blood. The latter Anatomists, as *Columbus* and *Fallopins* besides these parts, have made mention of another particle, which stands forth in the upper part of the privities, and also of the urinary passage, which joynes together those wings wee formerly mentioned. *Columbus* calls it *Tentigo*, *Fallopins* *Cleitoris*,

Cleitoris, Tentigo

whence proceeds that infamous word *Cleitorizein*, (which signifies impudently to handle that part.) But because it is an obscene part, let those which desire to know more of it, read the Authors which I cited,

CHAP. XXXV.

Of the Coats containing the Infant in the wombe, and of the Navell.

Their substance, magnitude, figure, and composition.

He membranes or coates containing the infant in the wombe of the mother, are of a spermaticke and nervous substance, having their matter from the seede of the mother. But they are nervous that so they may be the more easily extended, as it shall be necessary for the child. They are of good length and bredth, especially neare the time of deliverance, they are round in figure like the wombe.

Their composition is of veines, arteries, and their proper substance. The veines, and arteries, are distributed to them (whether obscurely, or manifestly, more or fewer) from the wombe by the *Cotyledones*, which have the same office, as long as the child is contained in the wombe, as the nipples or pappes of the nurses after it is borne. For thus the wombe brings the *Cotyledones*, or veines, degenerating into them, through the coates like certaine paps to the infant shut up in them.

Their number.

These coates are three in number according to *Galen*; one called the *Chorion*, Secundine, or afterbirth; the other *Allantoides*; the third *Amnios*. I find this number of coates in beasts, but not in women, unlesse peradventure any will reckon up in the number of the coates, the *Cotyledones* swollen up, and grown into a fleshie masse, which many skilfull in Anatomy doe write, which opinion notwithstanding we cannot receive as true. I could never in any place finde the *Allantoides* in women with child, neither in the infant borne in the sixth, seventh, eight, or in the full time, being the ninth moneth, although I have sought it with all possible diligence, the Midwives being set apart, which might have violated some of the coates.

But thus I went about this businesse, I devided the dead body of the mother crosswise upon the region of the wombe, and taking away all impediments, which might either hinder, or obscure our diligence, with as much dexteritie as was possible, we did not onely draw away that receptacle or den of the infant, from the inward surface of the wombe, to which it stucke by the *Cotyledones*, but we also tooke away the first membrane which we called *Chorion*, from that which lies next under it, called *Amnios*, without any rending or tearing; for thus we powred forth no moisture, whereby it might be said, that any coate, made for the containing of that humor, was rent, or torne. And then we diligently looked, having many witnesses and spectators present, if in any place there did appeare any distinction of these two membranes, the *Allantoides*, and *Amnios*, for the separating the contained humors, and for other uses which they mention.

But when we could perceive no such thing, we tooke the *Amnios* filled with moisture on the upper side, and having opened it, two servants so holding the apertion, that no moisture might flow out of it into the circumference of the *Chorion* or womb; then presently with sponges we drew out by little and little all the humiditie contained in it, the infant yet contained in it, which was fit to come forth, that so the coate *Amnios* being freed of this moisture, we might see whether there were any other humor contained in any other coate besides. But having done this with singular diligence and fidelity, we could see no other humor, nor no other separation of the membranes besides.

He shewes by three severall reasons that there is no *Allantoides*.

So that, from that time I have confidently held this opinion, that the infant in the wombe, is onely wrapped in two coates, the *Chorion* and *Amnios*. But yet not satisfied by this experience, that I might yet be more certaine concerning this *Allantoides*, having passed through the two former coates, I came to the infant, and I put a quill into its bladder, and blew it up as forceably as I could, so to trie, if by that blowing I might force the aire into that coate which we questioned, as some have written. But neither thus could I drive any aire from hence, through the navell into the controverted coate, but rather I found it to flie out of the bladder by the privities. Wherefore I am certainly perswaded that there is no *Allantoides*. Moreover I could never finde

finde nor see in the navell that passage called the *urachus*, which they affirme to be the beginning and originall of the coate *Allantoides*. But if it be granted that there is no such coate as the *Allantoides*, what discommoditie will arise hereof? specially seeing the sweate and urine of the infant may easily and without any discommoditie be received, collected and contained in the same coate, by reason of the small difference which is betweene them. But if any object that the urine by its sharpenesse and touching will hurt the infant; I will answer, there can be no so great sharpenesse in the urine of so small an infant, and that, if that there be any, it is tempered by the admixture of the gentle vapour of sweate.

Besides, if you consider, or have regard to the use of such an humor (which is to hold up the child, lest by its weight it breake the ties, by which it is bound to the wombe;) wee shall finde no humor more fit for this purpose than this serous, as which by its thicknesse is much more fit to beare up a weight, than the thinne and to liquide sweate. For so we see the sea or salt water carries greater weights without danger of drowning, than fresh rivers doe. Wherefore I conclude that there is no neede, that the urine should be kept and contained in one coate, and the sweate in another. The Ancients who have writ otherwise, have written from observations made in beasts. Wherefore we make but onely two coats the *Chorion* and *Amnios*, the one of which seeing it contains the other, they both so encompass the child, that they vest it on every side.

Fallopins in some sort seemes to be of this opinion; for he onely makes two coates; the *Chorion* and *Amnios*, but hee thinks the infant makes the water into a certaine part of the *Chorion*, as you may perceive by reading of his Observations. Both these coates are tied betweene themselves by the intercourse of most slender nervous fibers, and small vessels penetrating from the outer *Chorion* to the inner *Amnios*. Wherefore unless you warily handle these coates you may easily teare the *Amnios* in separating it. They are of the same temper with other membranes. Their use is different, for the *Chorion* is made both for the preservation of the vessels, which it receives from the wombe for the generating of the umbilicall veines and arteries, as also, to keepe whole and safe the parts which it invests.

Their temper
and use.

But the *Amnios* is to receive and containe the excrementitious and serous humors, which the child shut up in the wombe is accustomed to evacuate. But this coate is very thinne and soft, but strong and smooth, lest by its touch it might hurt the infant, whereupon it is called the Lamb-kinne coate.

CHAP. XXXVI.

Of the Navell.

He Navell followes these coates; It is a white body somewhat resembling the wreathen cord, or girdle of the *Franciscan Friers*, but that it hath not the knots standing so farre out, but onely swelling in certaine places, resembling a knot, onely lifted up on one side; it arises and takes its originall from a fleshie masse which we expressed by the name of

What the
navellis.

swelling *Cotyledones*, and goes into the midst of the lower belly of the infant, yea verily into the midst of the whole body, whose roote it is therefore said to be. For even as a tree by the roote, sucks nourishment from the earth, so the infant in the wombe drawes its nourishment by the navell. The greatnesse of it in breadth and thicknesse, equall the bignesse of the little finger. But it is a foote and a halfe long, so that children are brought forth with it, encompassing their middle, necke, armes, or legges. The figure of it is round. It is composed of two arteries, one veine and two coates. It hath these vessels from that great multitude of capillary veines and arteries, which are seene dispersed over the *Chorion*. Wherefore the veine entring in at the navell, penetrates from thence into the hollow part of the liver, where divided into two, according to *Galens* opinion, it makes the gate and hollow veines. But the arteries, caried by themselves the length of the navell, cast themselves into the *Iliaca*, which

Their Navell
is the Centre
of the body.

The figure
and compo-
sure.

Lib. de format;
factus in utero.

they make, as also all other, that from thence the vitall spirit may be carried by them over all the infant. It hath its two coates from the *Chorion*.

There is onely
one veine in a
childs navill,
but no
Urachus.

But seeing they are mutually woven and conjoynd without any *medium*, and are of a sufficient strength and thicknesse over all the navell, they may seeme to make the infants externall skinn and fleshie pannicle. I know very many reckon two umbilicall veines, as also arteries, and the *urachus* by, or through which the urine flowes into the coate *Allantoides*. But because this is not to be found in women, but onely in beasts, I willingly omit it, because I doe not intend to mention any parts, but such as belong to humane bodies. Yet if there be any, which can teach me, that these parts, which I thinke proper to brute beasts, are to be found in women, I will willingly confesse, and that to his credit, from whom I have reaped such benefit.

The other things that may be required concerning the navell as of its number, site, connexion, temper, and use, may easily appeare by that we have spoken before. For we have apparently set downe the use, when we said the navell was made for that purpose, that the infant may be nourished by it, as the tree by the roote, by reason of the continuation of the vessels thereof, with the preparing spermaticke vessels, made by God for that purpose, to whom be honour and glory for ever and ever. Amen.

The End of the third Booke.

THE

THE FOURTH BOOKE TREATING OF THE Vitall parts contained in the Chest.

The Preface.

Aving finished the first Booke of our Anatomy, in explanation of the naturall parts contained in the lower belly, now order requires, that we treat of the Brest; that so the parts in some sort already explained (I meane the veines and arteries) may bee dispatched after the same order and manner, without interposition of any other matter.

And besides also that we may the more exactly and chearefully shew the rest of the parts which remaine, as the head and limbs, knowing already the originall of those vessels which are dispersed through them. To this purpose, we will define what the Chest is, and then we will divide it into its parts. Thirdly, in these we will consider which parts containe, and which are contained, that so we may more happily finish our intended discourse.

CHAP. I.

What the Thorax, or the Chest is, into what parts it may be divided, and the nature of these parts.

He *Thorax* or Chest is the middle belly, terminated or bounded above with the collar-bones, below with the midriffe, before with the *Sternum* or brest, behind, with the twelve *Vertebra's* of the backe on both sides, with the true and bestarp ribs, and with the intercostall and intercartilagineous muscles. Nature hath given it this structure and composition, lest that being a defence for the vitall parts, against externall injuries, it should hinder respiration; which is no lesse needfull for the preservation of the native heate, diffused by the vitall spirits, and shut up in the heart, as in the fountaine thereof against internal injuries than the other forementioned parts against externall. For if the chest should have bin all bony, verily it had beene the stronger, but it would have hindred our respiration or breathing, which is performed by the dilating, and contracting thereof. Wherefore lest one of these should hinder the other, nature hath framed it, partly bony and gristlely, and partly fleshie. Some render another reason hereof, which is, that nature hath framed the chest, that it might here also observe the order used by it in the fabricke of things, which is, that it might conjoine the parts much disagreeing in their composure, as the lower belly, altogether fleshie, and the head all bony, by a *medium* partaker both of the bony and fleshie substance; which course wee see it hath observed in the connexion of the fire and water, by the interposition of the aire, of the earth and aire, by the water placed betweene them.

The contei-
ning parts of
the Chest.

Why nature
hath made
the Chest part
ly bony, partly
gistlely.

The number of
the bones of the
Sternon.

The Chest is divided into three parts, the upper, lower, and middle: the collar bones containe the upper, the midriffe the lower, and the *Sternon* the middle. The *Sternon* in *Galens* opinion is composed of seven bones, I beleeeve by reason of the great stature of the people that lived then. Now in our times you shall oft finde it compact of three, foure, or five bones, although we will not deny but that we have often observed it, (especially in young bodies) to consist of seven or eight bones.

Wherefore those who have fewer bones in number in their *Sternon*, have them larger, that they might be sufficient to receive the ribbes. This is the common opinion of the *Sternon*. Yet *Fallopins* hath described it farre otherwise, wherefore let those who desire to know more hereof, looke in his observations.

Cartilago scuti-
formis, the breast-
blade.

At the lower part of the *Sternon* there is a gristle, called commonly *Furcula*, and *Malum granatum*, or the Pomegranate, because it resembles that fruite; others call it *Cartilago scutiformis*, that is, the breast-blade.

It is placed there to be as it were a bulwarke or defence to the mouth of the stomacke, endued with most exquisite sense; and also that it should doe the like to that part of the midriffe, which the liver beares up in that place, situate above the orifice of the ventricule by the ligament comming betweene, descending from the lower part of the same gristle into the upper part of the liver.

The common people thinke that this gristle sometimes falls downe. But it so adheares, and is united to the bones of the *Sternon*, that the falling thereof may seeme to be without any danger, although oft times it may bee so moistened with watery and ferous humidities, with which the orifice of the stomacke abounds, that as it were soaked and drunke with these, it may be so relaxed, that it may seeme to be out of its place; in which case it may be pressed and forced by the hand, into the former place and seate, as also by applying outwardly, and taking inwardly astringent and drying medicines to exhaust the superfluous humiditie.

This gristle at its beginning is narrow, but more broad and obtuse at its end, somewhat resembling the round or blunt point of a sword, whereupon it is also called *Cartilago Ensiformis* or the swordlike gristle. In some it hath a double, in others a single point.

In old people it degenerates into a bone. Now because we make mention of this gristle, we will shew both what a gristle is, and how many differences thereof there be, that henceforward as often as wee shall have occasion to speake of a gristle, you may understand what it is.

What a Gristle
is.

A gristle is a simlar part of our bodies, next to a bone most terrestriall, cold, drie, hard, weighty and without sense, differing from a bone in drie nesse onely, the which is more in a bone. Wherefore a gristle being lost cannot be regenerated, like as a bone without the interposition of a *Callus*.

The differences
thereof.

The difference of these are almost the same with bones, that is from their consistence, substance, greatnesse, number, site, figure, connexion, action, and use. Omitting the other for brevities sake, I will only handle those differences which arise from site, use, and connexion. Therefore gristles, either adhere to the bones, or of, and by themselves make some part, as the gristles of the eyelids called *Tarsi*, of the *Epiglottis* and throatle. And others which adhere to bones, either adhere by the interposition of no medium, as those which come betweene the bones of the *Sternon*, the collar bones, the share and hanch bones and others; or by a ligament comming betweene, as those which are at the ends of the bastard ribs to the *Sternon* by the meanes of a ligament, that by those ligaments being softer than a gristle, the motions of the chest, may be more quickly and safely performed. The gristles which depend on bones, doe not onely yeeld strength to the bones, but to themselves, and the parts contained in them, against such things as may breake and bruise them. The gristles of the *Sternon*, and at the ends of the bastard ribs are of this sort.

Their twofold
use.

By this we may gather that the gristles have a double use, one to polish and levigate the parts to which that slippery smoothnesse was necessary for performance of their dutie; and for this use serve the gristles which are at the joynts, to make their motions the more nimble. The other use is to defend those parts upon which they are placed, from externall injuries, by breaking violent

violent assaults, by somewhat yeelding to their impression, no otherwise than soft things opposed against cannon shot. Wee will prosecute the other differences of gristles in their place, as occasion shall be offered and required.

CHAP. II.

Of the containing, and contained parts of the Chest.

He containing parts of the chest are both the skinnies, the fleshie pannicle, the fat, the breasts, the common coate of the muscles, the muscles of that place, the forementioned bones, the coate investing the ribbes and the *Diaphragma* or midriffe. The parts contained are the *Mediaſtinum*, the *Pericardium* or purse of the heart, the heart, the lungs & their vessels. Of the containing parts, some are common to all the body, or the most part thereof, as both the skins, the fleshie pannicle and fat. Of which being we have spoken in our first Booke, there is no neede now further to insist upon; Others are proper to the chest, as its muscles, of which we will speake in their place, the breasts, the forementioned bones, the membrane investing the ribs, and the *Diaphragma* or midriffe.

The division
of the chest
into its parts.

Wee will treat of all these in order, after we have first shewed you the way, how you may separate the skinnie from the rest of the chest. Putting your knife downe even to the perfect division of the skinnie, you must draw a straite line from the upper part of the lower belley, even to the chinne; then draw another straight line, overthwart at the collar bones even to the shoulder-blades; and in the places beneath the collar-bones: (if you desire to shunne prolixitie) you may at once separate both the skinnies, the fleshie pannicle, the fat, and common coate of the muscles; because these parts were shewed and spoken of in the dissection of the lower belley.

Yet you must reserve the breasts in dissecting of the bodies of women; wherefore from the upper parts of the breasts, as artificially as you can, separate onely the skin from the parts lying under it, that so you may shew the Pannicle which there becommeth fleshie and musculous, and is so spread over the necke, and parts of the face, even to the rootes of the haire.

CHAP. III.

Of the Breasts or Dugges.

He Breasts, as wee said, when we spoke of the nature of glandules, are of a glandulous substance, white, rare, or spongiouse, in maidens, and women that doe not give sucke, they are more solid and not so large.

Their substance,

Wherefore the bignesse of the Dugges is different, although of a sufficient magnitude in all. Their figure is round, somewhat long, and in some sort Pyramidall. Their composure is of the skinnie, the fleshie pannicle, glandules, fat, nerves, veines, and arteries, descending to them from the *Axillaris* under the *Sternum* betwixt the fourth and fifth, and sometimes the sixth of the true ribbes.

Magnitude,
Figure.

Composure

And there they are divided into infinite rivelets by the interposition of the glandules and fat, by which fit matter may be brought, to be changed into milke by the facultie of the dugges.

Wee will speake no more of the nature of glandules, or kernels, as having treated of them before; onely we will add this, that some of the glandules have nerves, as those of the breasts, which they receive from the parts lying under them, that is, from the intercostall, by which it comes to passe that they have most exquisite sense.

Which glandules have nerves and which have none,

Others want a nerve, as those which serve onely for division of the vessels, and which have no action, but onely use.

They be two in number, on each side one, seated at the sides of the *Sternon* upon the fourth fifth and sixth true ribs.

Their Connexion.

How the breasts and wombe communicate each with other.

Wherefore they have connexion with the mentioned parts with their body, but by their vessels with all other parts, but especially with the wombe by the reliques of the mamillary veins and arteryes, which descend downe at the sides of the breast-blade; in which place these veins insinuating themselves through the substance of the muscles, are a litle above the navill conjoined with the *Epigastricks*, whose originall is in some sort opposite to the *Hypogastricks*, which send forth branches to the wombe. By the meeting of these it is more likely that this commerce should arise, than from other and those almost capillary branches, which are sometimes seene to descend to the wombe from the *Epigastrick*.

Their temper.

*Recede & secrete.
Their action and use.

They are of a cold and moist temper, wherefore they say that the blood by being converted into milke * becomes raw, flegmaticke and white by the force of the proper flesh of the dugs. Their action is to prepare nourishment for the new borne babe, to warme the heart from whence they have received heat, and to adorne the breast.

The Nipples.

By this you may know that some Glandules have action, others use, and some both. At the top of the dugs there are certaine hillockes, or eminencies called teats or nipples, by sucking of which the child is nourished through certaine small and crooked passages; which though they appeare manifest to the sight, whilest you presse out the milke by pressing the dug, yet when the milke is pressed out they doe not appeare, nor so much as admit the point of a needle, by reason of the crooked wayes, made by nature in these passages, for this use, that the milke being perfectly made should not flow out of its owne accord against the nurses will. For so the seed is retained and kept for a certaine time in the Prostats.

CHAP. IIII.

* Of the Clavicles, or Coller bones and Ribs.

IF we should handle these parts after the common order, we should now treat of the Muscles of the Chest which move the arme, and serve for respiration, and which first offer themselves to our sight.

But for that they cannot be fitly shewed, unlesse wee hurt the muscles of the shoulder blade and necke, therefore I thinke it better, to deferre the explanation of these muscles untill such time as I have shewed the rest of the contained and containing parts, not onely of the chest, but also of the head, that having finished these we may come to a full demonstration of all the rest of the muscles, beginning with those of the head, which wee first meet with, and so prosecuting the rest even to the muscles of the feet, as they shall seeme to offer themselves more fitly to dissection, that so, as much as lyes in us, we may shunne confusion.

Wherefore returned to our proposed taske, after the foresaid muscles come the Collar bones, the *Sternon* and ribs.

But that these parts may be the more easily understood, wee must first know what a bone is, and whence the differences thereof are drawne.

What a Bone is.

Therefore a bone is a part of our body most terrestriall, cold, dry, hard, wanting all manifest sense, if the teeth be excepted.

A double sense
Lib. I. de Locis
affectis.

I said manifest sense, that you may understand that the parts have a double sense of touching, the one manifest, such as resides in the flesh, skin, membranes, nerves, Teeth and certaine other parts; the other obscure, yet which may suffice to discern the helping and hurting tactile qualityes, such sense the bowels and bones have; for very small fibers of the nerves are disseminated to these parts by mediation of their coat, or membrane, I say so small, that they canne scarce be discerned by the eyes, unlesse (as *Galen* saith) by plucking such coats away from the parts.

But

But it is no marvaile if nature would have these parts in like manner to have such small veines, contrary to the lungs and most part of the Muscles, onely to yeild so much nourishment to the part, as should be needfull; for seeing the substance of the bones is cold, hard, dense and solid, it wastes the lesse.

Why the bones have such small veines.

Wherefore they need not so much blood for their nourishment, as the hot and soft parts; and besides the lesser bones have neither veines, nor arteries, but draw fit nourishment, onely by the force of the attractive faculty implanted in them.

The differences of bones are taken from many things, as from their *Apophyses*, *Epi-physes*, gristles, necks, heads, solidity, cavity, eminencies, marrow, consistence, dignes, number, figure, site. Wee will prosecute all these as they shall offer themselves in the demonstration of the bones; to which doctrine we will give a beginning at the Clavicles or collar bones.

Whence the difference of bones may be taken.

The Clavicles are two very hard and solid bones, without any great or notable cavity, situate on each side betwixt the side and upper part of the *sternon* and top of the shoulder-blade, for the strength and stability of these parts, whence they take the name of *Clavicula* Clavicles (from the Greeke *κλεις*, which signifies a key or any other bar or fastning of a doore.) They carry the shape of a surgeons Levatory.

The Clavicles or collar bones

But you must note that the Clavicles seemes to be fastned to the *sternon* by the mediation of a gristly bone. Moreover the space and cavity contained within the Collar bones is called by the Latines *Iugulum*, by the French the upper *furcul*, because the jugular veines passe that way; it sticks to the upper proësse of the shoulder by a Gristle which *Galen* calls the small gristle bone, although it be nothing else but a pro-

Lib. 13. du xij^e part. Cap. 11.

duction of the *Os Iuguli*. For the *sternon*, which we said is framed of diverse bones, as sometimes 3, sometimes 4, 5, 6, 7, and sometimes 8, you must note they are very spongy and full of pores, and of a farre softer consistence than the collar bones, wherefore more subject to corruption; besides they are mutually joined by interposition of muscles. Their use is to be as a shield to defend the vitall parts.

The Ribs are 24. in number, on each side 12, seven of these are called true or perfect ribs, because they make a circle, at the one end joined to the *sternon*, on the other to the *vertebra's*; the other are called bastard or short ribs because they fall short in their way and come not to the *sternon*; but they are fastened on the fore-side to the *sternon* by gristles and ligaments, but on the back part to the transverse *vertebra's* of the back-bone, and to the sides of the said *vertebra's*. But the short ribs are onely knit to the *vertebra's*, wherefore that part of the *vertebra's* is called the root of the ribs.

The Ribs.

The exterior or fore-part of the Bastard or short ribs is gristly, that they should not be broken, and that they might be the easier lifted up in the distensions of the stomach filled with meat. They are of a consistence sufficiently hard, yet more towards their root, than at the *sternon*, where they come nearer together, and are more hardly broken; they are smooth both within and without, but in the midst they have some signe of being double, or hollow to receive the veines and arteryes, which nourish their bony substance; they are fashioned like a bow; their use is the same with the *sternon*, and besides to carry and strengthen the muscles serving for respiration.

Their consistence.

CHAP. V.

The Anatomical Administration of the Sternon.

He Coate investing the ribs, which the common Anatomists call *Pleura*, is the last of the containing parts of the Chest, which because it lies hid in the inner part thereof, it cannot be showne unlesse by pulling asunder of the *Sternon*; wherefore wee must now shew the manner of opening the *Sternon*, that hereby we may not violate the originall or interion of any of the muscles. Wherefore first you must understand that he which will shew in their proper place the originall and insertion of the pectorall muscles, of the *Mastoides*, of the two muscles of the bone *Hyois*, of the Muscles *subclavii* and *intercostalaginei*,

vilaginei, ought first of all to separate all the pectorall muscles from the *sternon* and the gristles from the true ribs; then to cut the ligaments, next the bones themselves, even from the sixth true rib to the clavicles.

And then shewing the *Mediastinum* stretched under the *sternon* all the length thereof, he must separate the *sternon* with his knife and bend it up to the clavicles, and there cut it, reserving together with it the foure muscles, that is, the two *Mastoides* and the two moving the bone *Hyois*, because they either wholly or for the most part arise from the *sternon*.

Lastly the Clavicles being somewhat thrust upwards, the Gristles must on each side be turned outwards towards the arme; that so the containing parts of the chest may not onely lye open to view and be easily shewed, but also the muscles may bee contained in their place, untill they come to be shewed in their order.

And because the Collar bones must be lifted up very high, that the recurrent nerves may be more easily scene and the distribution of the veines and arteries, the two small subclavian muscles one on each side must bee shewne by the way, who have their originall from the inner and fore part of the Clavicles, and an oblique descent to the *sternon* towards the gristle of the first rib.

For the Clavicles cannot be thus separated, but that these muscles must be violated and spoiled. Also you may divide the *sternon* in the midst, that you may shew the inward pectorall muscles whole, having separated the muscles which arise from the upper part. All which things being performed as they ought, we must come to the Coat investing the ribs and then to the *Mediastinum* as arising from it.

CHAP. VI.

Of the Pleura, or coat investing the Ribs.

What the
membrane in-
vesting the
Ribs is,

He *Tunica subcostalis*, or coat investing the ribs being the last of the containing parts of the Chest, is a large and a broad membrane answerable in proportion of use and action to the *Peritonaeum* of the lower belly. For as the *Peritonaeum* generally and particularly covers all the naturall parts, binding and holding them in their places, so this coat invests all the vitall parts in generall because it is stretched over all the inside of the Chest, but in particular, whilst it gives each a coate from it selfe.

Its originall.

It hath its originall from the *Periostium*, (or as others will have it from the *pericranium*,) investing the *vertebra's* of the Chest at the roots of the ribs. Wherefore it stickes very fast to the ribs, scarce to be separated, as also to all the parts bounding the Chest, and contained in it.

Vesalius reprehends *Galen*, because he said, that this was double on both sides; yet *Columbus* defends *Galen*, and verily it is scene to be double in the inner part of the Chest, under the ribs and the muscles of the ribs, that in that space there may bee way for the veines, arteryes and nerves.

Whether, as
there is a two-
fold pleurisie,
so also a
double Pleura

Some have made it two fold, and divided it into the internall and externall; as those which have made two sorts of pleurisy, the true and bastard; placing the externall above the Ribs and intercostall muscles; but the internall under the Ribs, muscles, *Diaphragma* and *sternon*.

The Magni-
tude and
figure.

But we to shun ambiguity, intend only to prosecute those things which are manifest to the eyes; wherefore we say that the ribs are lined on the inside with a double coate; one which immediatly and firmly stickes to them on every side called the *Periostium*, which is common to them and other bones.

The other which lyes upon that *Periostium* and on the inside invests all the ribs, whence it is called the *subcostalis tunica*. The substance, temper and composure are the same, as in other membranes. The magnitude in length, as also the figure is the same with the compasse of the inner part of the chest; the thicknesse of it is very little. This coat is commonly called the *Pleura* from the name of the part which it covers or lines (for the Greekes call the ribs *πλευραι*,) and in like manner which happens betwixt

betwixt the *Periostium* and this *Pleura*, is called either a true or bastard *Pleurisy*.

CHAP. VII.

Of the *Mediastinum*

NOW wee must speake of the parts contained in the Chest, seeing we have already handled the containing, beginning with the *Mediastinum* as being a part which in dissection first presents it selfe to our sight. The *Mediastinum* is of the same substance, thicknes, composure, number, temper as the *Pleura*. For the substance of the *Mediastinum* is membranous, and though it be stretched all the length of the Chest, yet it is of a small thicknes, receiving veines, nerves and arteryes from all the parts to which it is knit, like as the *Pleura* doth; but especially from the mamillary vessels descending under the *sternon*. The substance and magnitude

It is in number one, but it is made of two membranes produced from the sub-costall, for this ascending on each side by the hollownesse of the chest to the *sternon*, and then at right angles it is reflected to the bodyes of the *vertebra's*, whence the *Pleura* hath its originall.

In that reflection there is so much distance between each membrane, as may bee sufficient to receive 2 fingers. For otherwise, seeing that they cannot penetrate through the hart, it was fit each side of the *Pleura* should turne to the *Pericardium*, that so they might arive at the appointed place without offence. Nether yet is that space void and empty, but woven with many small nervous fibers; *Columbus* adds, that, that place is often filled with a certaine humor besides nature, which you may draw out, or evacuate by opening the *sternon*.

Yet I would gladly learne of *Columbus*, by what signes we may know that such an humor is contained there. For the figure, the *Mediastinum* with the *Pleura* on each side represents the figure of a Leather bottle, whose flat side is the *Mediastinum*, whose other side the *Pleura*; the bottome that part of the *pleura* which is next the Midriff, the mouth the upper part of the *Pleura* at the first ribs. We shewed the site and connexion of the *Mediastinum*, when we declared its originall. The figure.

The use thereof is to separate the vitall parts, as it were into 2 cells, the right and left, that if peradventure it happen that the one be hurt, the creature may live by the benefit of the other. The use.

And it hath another use which is to prop and hold up the *Pericardium*; that it fall not uppon the heart with its weight, but tossed with the motions of the heart and Chest, it may move to this or that side.

CHAP. VIII.

Of the Diaphragma or Midriffe.

ALTHOUGH the Midriffe may seeme to be accounted rather a part containing than contained, yet for commodities sake we have deferred the demonstration thereof till now. Therefore it is a muscle round and long, terminating the lower part of the Chest. What the midriffe is.

It is of the same substance, composition and temper, as the muscles of the *Epigastrium*, it is made of two coats the lower whereof is from the *Peritoneum*, and the upper from the *Pleura*. Which getting to them flesh but not there, but in their circumference, by the benefit of the blood brought thither by the veines and arteries distributed through it, turne into a muscle, whose middle is nervous and membranous, but the extremities by which it is inserted, one while fleshy as in that part next to the bastard ribs, another while tendonous, as where it touches the first & second *vertebra's* of the loines, for it ends in them by 2 tendons manifest enough. It is one in number, interposed with an oblique site betwixt the naturall and vitall parts. Its substance, composition &c.

Connexion. It hath connexion with the lower part of the *sternon* and short ribs, and the two first *vertebra's* of the loines, but by its coats and vessels with the parts from whence it received them.

Quantity. The extent thereof is equall to the compasse of the lower part of the Chest. The length of it is from the breast blade even to the first and second *vertebra* of the loines. The thicknes is diverse, for it is far thicker in its fleshy extremity, than in its nervous originall.

Action. The Action thereof is to helpe the expulsion of the Excrements by the mutuall assistance of the *Epigastrick* muscles, but the chiefe use is for respiration, of which it is one of the prime instruments. This partition the Ancients called *Phrenes*, because the inflammation thereof caused like symptomes as the inflammation of the Braine, by reason of the large nerves on each side one which come to it directly & primarily from the third, fourth and fifth *vertebra* of the neck. This muscle differs from other muscles, specially in figure. It is preforated in three places, to giue way or passage to the ascendent Hollow-veine, to the Artery *Aorta*, and the Gullet.

Why the
Diaphragma
was called
Phrenes.

CHAP. IX.

Of the Lungs.

Their substance.
quantity.
The Lobes thereof.

 The Lungs are of a soft substance and flesh, rare and like a sponge, of a various colour pale red, their quantity is sufficiently large, for most commonly they are divided into 4 lobes disjoined with a manifest and visible division, on each side two, whereby they may be the more easily opened and contracted, and the aire may the better enter.

Besides also in large bodyes, who have a very great chest, there is found a fifth lobe, arising from the second lobe of the right side, as a cushion, or bolster to beare up the hollow veine ascending from the midriffe to the heart.

In little men who have a shorter Chest, because the Heart is so neere as to touch the *Diaphragma*, this Lobe is not seene, yet it is alwayes found in Dogges.

Figure.

The Lungs represent the figure or shape of an Oxes foot, or hoof, for like it they are thicker in their *basis*, but slenderer in their circumference, as you may see in blowing them up, by the weazon, with your mouth or a paire of bellows. They are compounded of a coate comming from the *Pleura*, which on each side receives sufficient number of nerves from the sixth conjugation; and also of the *Vena arteriosa* comming from the right ventricle of the heart, and the *Arteria venosa* from the left, as shall be shewed in the Anatomy of the heart; besides the *Aspera arteria* or Wezon comming from the throat, and lastly its owne flesh, which is nothing else than the concretion of cholerick blood poured out like foame about the divisions of the fore-said vessels, as we have said of other parts.

Composition.

The body of the Lungs is one in number, unlesse you will divide it into two, by reason of the variety of its site, because the Lobes of the Lungs stretched forth into the right & left side doe almost involve all the heart, that so they may defend it against the hardnes of the bones which are about it; they are tyed to the heart, cheifly at its *basis*, but to the roots of the ribs and their *vertebra's* by the coat it hath from thence; but by the vessels to these parts from whence they proceed. But oft times presently from the first and naturall conformation they are bound to the circumference of the ribs by certaine thin membranous productions which descend from thence to the Lungs, otherwaies they are tyed to the ribs by the *Pleura*.

The sticking
of the lungs to
the Ribs.

Their nourishment.

The nourishment of the Lungs is unlike to the nourishment of other parts of the body; for you cannot find a part equally rare, light and full of aire, which may be nourished with blood equally thin and vaporous. In temper they incline more to heat than to cold, whether you have regard to their compolure of cholerick blood, or their use, which is to prepare and alter the aire that it hurt not the heart by its coldnes. The Lungs is the instrument of voice and breathing by the Weazon or windpipe. For the Lobes are the instruments of voice, and the ligaments, of respiration. But the

Larynx

Larinx or Throtle is the chiefe instrument of the voice, for the Weazon first prepares the voice for the Throtle, in which it being in some measure formed is perfected in the Pallate of the mouth, as in the upper part of a lute, or such like instrument, by the help of the *Gargareon* or *uvula* as a certaine quill to play withall.

But as long as one holds his breath, he cannot speak; for then the muscles of the *Larinx*, Ribs, the *Diaphragma* and the *Epigastrick* muscles are pressed downe, whence proceeds a suppression of the vocall matter, which must be sent forth, in making or uttering a voice.

Nature would have the Lungs light for many reasons, the first is that seeing they are of themselves immoveable, they might be more obsequious and ready to follow the motion of the chest, for when it is straitened, the Lungs are straitened and subside with it; and when it is dilated, they also are dilated, and swell so big that they almost fill up all the upper capacity thereof.

Why the lungs are light.

Another cause is that by this their rarity they might more easily admit the entering Aire, at such times as they have much, or suddaine necessity, as in running a race.

And lastly, that in Pleurifies and other purulent abscesses of the Chest the Pus or matter poured forth into the capacity of the Chest may be sucked in by the rare substance of the Lungs, and by that meanes the sooner sent forth and expectorated.

The use of respiration is to coole and temper the raging heat of the Heart. For it is cooled in drawing in the breath by the coole aire, and in sending out thereof by avoiding the hot fuliginous vapour. Therefore the Chest performes two contrary motions, for whilest it is dilated it drawes in the encompassing aire, and when it is depressed it expels the fuliginous vapour of the Heart; which any one may easily perceive by the example of a paire of Smithes bellowses.

The use of Respiration, or breathing.

CHAP. X.

Of the Pericardium or purse of the Heart.

The *Pericardium* is as it were the house of the Heart, which arising at the basis thereof (either the ligaments of the *vertebra's* situate there or els the vessels of the heart yeilding it matter) is of a nervous, thick and dense substance without any fibers. It retains the figure of the Heart, and leaves an empty space for the heart to performe its proper motions. Wherefore the bignes of the *Pericardium* exceeds that of the heart.

Whence it hath its matter.

It consists of a double coate, one proper of which wee have spoken, another common coming from the *pleura*; and also of veines, arteries and nerves; the vessels partly coming from the mamillary, partly from the *Diaphragma*, chiefly there where it touches it; the nerves come on each side from the sixth conjugation.

It is onely one, placed about the heart and annexed to it at the Basis thereof by its membranes, to the originall of the Lungs, and the *vertebra's* lying under them, and by the vessels to the parts from whence it received them. It is of a cold and dry temper as every membrane is.

Number and connexion.

The use thereof is to cover the heart, and preserve it in its native humidity, by a certaine naturall moysture contained in it, unles you had rather say that the moisture we see contained in the *Pericardium*, is generated in it after death by the condensation and concretion of the spirits. Although this seemes not very likely; because it growes and is heaped up in so great quantity in living bodyes, that it hinders the motion of the heart, and causes such palpitation or violent beating thereof; that it often suffocates a man.

Viz

For this Palpitation happens also to hearty and stout men, whose harts are hot, but blood thin and waterish by reason of some infirmity of the stomach or Liver; and this humour may be generated of vapours which on every side exhale into the *pericardium* from the blood boiling in the ventricles of the heart, where kept in by the density thereof, they turne into yellowish moisture, as we see it happens in an Alembek.

From whence the matter of the watery humor contained in the *Pericardium*.

Nature would have the *pericardium* of a dense and hard consistence, that by the force thereof

The Consistence.

thereof the heart might bee kept in better state ; for if the *Pericardium* had beene bony , it would have made the heart like iron by the continuall attrition ; on the contrary, if it had beene soft and fungous, it would have made it spongy and soft like the Lungs.

CHAP. XXX.

Of the Heart.

What the heart is, and of what substance.

He Heart the chiefe mansion of the Soule, the organe of the vitall faculty, the beginning of life, the fountaine of the vitall spirits, & so consequently the continuall nourisher of the vitall heate, the first living and last dying, which because it must have a naturall motion of it self, was made of a dense solide and more compact substance than any other part of the body.

The three sorts of fibers of the Heart.

The flesh thereof is woven with three sorts of fibers, for it hath the right in the inner part descending from the *basis* into the point, that they might dilate it, and so draw the blood from the hollow veine into the receptacles thereof, and the breath or aire from the lungs by the *Arteria venosa*; it hath the transverse without, which passe through the right at right angles, to contract the Heart, and so drive the vitall spirits into the great Artery *Aorta*, and the cholericke blood to the Lungs by the *vena arteriosa*, for their nourishment; It hath the oblique in the midst to containe the Aire and blood drawne thither by the forementioned vessels untill they be sufficiently elaborate by the heart.

All these fibers doe their parts by contracting themselves towards their originall, as the right from the point of the heart towards the *basis*, whereby it comes to passe that by this contraction of the fibers the heart dilated becomes shorter, but broader, no otherwise than it is made more long and narrow by the contraction of the transverse, but by the drawing of the oblique it is lessened in that part which looks towards the *vertebra's*, which chiefly appears in the point thereof.

The magnitude

It is of an indifferent bignes, but yet in some bigger, in some lesse according to the diverse temper of Cold or hot men, as wee noted in the liver.

Figure.

The figure thereof is Pyramidall, that is, it is broader in the *basis*, and narrower at his round point.

Composition

It is composed of the most dense flesh of all the body, by the affusion of blood at the divisions and foldings of the vessels, and there concrete; as it happens also to the other Entrailles. For the blood being there a litle more dryed, than that which is concrete for the making of the Liver, turns into a fleshy substance more dense than the common flesh, even as in hollow ulcers, when they come to a cicatrize.

The proper vessels.

It hath the Coronall veines and arteryes, which it receives either on the right side from the hollow veine, or on the left from the *basis* at the entranc of the Artery *Aorta*.

The Nerves,

You cannot by your Eye discern that the Heart hath any other Nerves than those which come to it with the *Pleura*.

Yet I have plainly enough observed others in certaine beasts, which have great Hearts, as swine; they appeared seated under the fat which covers the vessels, and *basis* of the heart, lest the humid substance of these parts should be dissolved and dissipated by the burning heat of the Heart. Whereby you may perceive that the heat of the heart is different from the Elementary heat, as that which suffers fat to grow about this Entraille, where otherwise it doth not concrete unlesse by cold or a remisse heat, which thing is chiefly worth admiration.

Number and site.

The Heart is one alone, scituate most commonly upon the fourth *Vertebra* of the Chest, which is in the midst of the Chest. Yet some thinke that it inclines somewhat to the left side because we there feele the motion or beating thereof; but that happens by reason of its left ventricle, which being it is filled with many spirits, and the beginning of the arteryes, it beats far more vehemently, than the right. It required that seat by the decree of Nature, because that Region is the most safe and armed,

armed, and besides it is here on every side covered as it were with the hands of the Lungs.

It hath connexion with the fore mentioned *Vertebra's*, but by the parts composing it, with those parts from whence it hath them; with the Lungs by the *Vena arteriosa*, and the *Arteria venosa*, and lastly with all the parts of the body by the Arteries which it sends to them all.

Connexion.

It is of a hot and moist temper, as every fleshy part is. The action thereof is, first to prepare the blood in its right ventricle, for the fit nourishment of the Lungs, for from hence it is that *Galen* saith; this right ventricle was made for the necessity of the lungs. Secondly to generate the vitall spirits in its left ventricle for the use of the whole body. But this spirit is nothing els than a certaine middle substance between aire and blood fit to preserve and carry the native heat, wherefore it is named the vitall, as being the author and preserver of life. In the inner parts of the heart there present themselves to our consideration the ventricles and the parts contained in the ventricles and between them; such are the *Valvula* or valves, the vessels and their mouthes, their distribution into the lungs, the wall or partition, and the two productions or Eares of the heart; which because they are doubtful, whether they may be reckoned amongst the externall or internall parts of the heart, I will here handle in the first place.

Temper and action.

What the vitall spirit is.

Therefore these *Auricle* or Eares are of a soft and nervous substance, compact of three sorts of fibers, that so by their softnesse they might the more easily follow the motions of the heart, and so breake the violence of the matters entring the heart with great force when it is dilated. For otherwise by their violent and abundant entrance they might hurt the heart, and as it were overwhelme and suffocate it; but they have that capacity which we see given by nature, that so they might as it were keep in store the blood and aire, and then by litle and litle draw it forth for the use or necessity of the heart. But if any enquire, if such matters may be drawne into the heart by the only force of the *Diastole ad fugam vacui*, for avoiding of emptinesse; I will answer that that drawing in, or attraction is caused by the heat of the heart; which continually drawes these matters to it no otherwise than a fire drawes the adjacent Aire, and the flame of a candle the tallow which is about the weake for nourishments sake. Whilest the heart is dilated it drawes the aire, whilest it is drawne together or contracted, it expells it. This motion of the heart is absolutely naturall, as the motion of the Lungs is animall. Some adde a third cause of the attraction of the heart; to wit the similitude of the whole substance. But in my judgment, this rather takes place in that attraction which is of blood by the *vena coronales* for the proper nourishment of the heart, than in that which is performed for attraction of matters for the benefit of the whole body.

The *Auricula Cordis*, or eares of the heart.

These eares differ in quantity, for the right is far more capacious than the left because it was made to receive a greater abundance of matter. They are two in number, on each side one, scituate at the *Basis* of the heart; The greater at the entrance of the hollow veine into the heart, the lesse at the entrance of the *veinous* and of the great Artery with which parts they both have connexion. We have formerly declared what use they have; that is, to break the violence of the matters, and besides to bee stayes or props to the *Arteria venosa* and great Arterye, which could not sustaine so rapid and violent a motion as that of the Heart by reason of their tenderesse of substance.

Their magnitude and number.

Their use.

Of the ventricles of the Heart.

The ventricles are in number two, on each side one, distinguished with a fleshy partition strong enough, having many holes in the superficies, yet no where pearcing through.

The partition betweene the ventricles of the Heart.

The right of these ventricles is the bigger and incompassed with the softer and rarer flesh; the left is the lesser but is engirt with a threefold more dense and compact flesh; for the right ventricle was made for a place to receive the blood brought by the hollow veine, and for distributing of it, partly by the *vena arteriosa* into the Lungs for

Why the right ventricle is more capacious and less compact.

for their nourishment, partly into the left ventricle, by sweating through the wallor partition, to yeild matter for the generation of the vitall spirits.

Why the right ventricle is more capacious and lesse compact.

Therefore because it was needfull there should be so great a quantity of this blood, it was likewise fit that there should be a place proportionable to receive that matter. And because the blood which was to bee received in the right ventricle was more thicke, it was not so needfull, that the flesh to containe it should be so compact; but on the contrary the arterious blood and vitall spirit have need of a more dense receptacle, for feare of wasting and lest they should vanish into aire; and also lesse roome that so the heat being united might become the stronger, and more powerfully set upon the elaboration of the blood and spirits.

The action of the right ventricle.

Therefore the right ventricle of the heart is made for the preparation of the blood appointed for the nourishment of the Lungs, and the generation of the vitall spirits, as the lungs are made for the mitigation, or quallifying of the Aire. Which works were necessary, if the Physicall Axiome bee true; That like is nourished by like, as the rare and spongiouse lungs with more subtle blood; the substance of the heart grosse and dense, with the veinous blood as it flowes from the Liver, that is grosse.

And it hath its Cororall veines from the Hollow veine, that it might thence drawe as much as should be sufficient.

The action of the left ventricle.

But the left ventricle is for the perfecting of the vitall spirit, and the preservation of the native heat.

Of the Orifices and Valves of the Heart.

The uses of the foure orifices of the Heart.

There be foure Orifices of the heart, two in the right, & as many in the left ventricle; the greater of the two former gives passage to the veine, or the blood carried by the hollow veine to the heart; the lesser opens a passage to the *vena arteriosa* or the cholerick blood carryed in it for the nourishment of the lungs.

The larger of the two other makes a way for the distribution of the Artery *Aorta* and the vitall spirit through all the body; but the lesser gives egressive and regressive, to the *Arteria venosa*, or to the aire and fuliginous vapours. And because it was convenient that the matters should bee admitted into their proper ventricles by these orifices, by the *Diastole*, to wit, into the right ventricle by the greater orifice, and into the left by the lesser, and because on the contrary it was fit that the matters should be expelled by the *systole* from their ventricles by the fore-mentioned orifices.

The valves.

Therefore nature to all these orifices hath put cleaven valves, that is to say, fixe in the right ventricle, that there might bee three to each orifice; five in the left, that the greater orifice might have three, and the lesser two, for the reason we will presently give.

How they differ.

These valves differ many wayes; first in action; for some of them carry in matter to the heart, others hinder that which is gone out that it come not back againe; Secondly they differ in site, for those which bring in have membranes without, looking in; those which carry out have them within looking out. Thirdly in figure, for those which carry in, have a pyramidall figure, but those which hinder the coming back againe are made in the shape of the Roman letter C. Fourthly in substance, for the former for the most part are fleshy, or woven with fleshy fibers into certaine fleshy knots ending towards the point of the heart. The latter are wholly membranous.

Number.

Fifthly they differ in number, for there be only five which bring in, three in the right ventricle at the greater orifice, and two in the left at the lesser orifice; those which prohibite the coming back are fixe in each ventricle, three at each orifice. Lastly they differ in motion; for the fleshy ones are opened in the *Diastole* for the bringing in of blood and spirit, and contrarywise are shut in the *systole*, that they may containe all or the greater part of that they brought in. The membranous on the contrary are opened in the *systole* to give passage forth to the blood and spirits over all the body, but shut in the *Diastole*, that that which is excluded might not flow backe into the Heart. But you shall observe that nature hath placed onely two valves at the Orifice of the *Arteria Venosa*, because it was needfull that this Orifice should bee alwayes open, either wholly, or certainly a third parte thereof; that

Why there be onely two valves at the *Arteria venosa*

the

the Aire might continually be drawne into the heart by this orifice in inspiration, and sent forth by expiration in the contraction of the heart. Whereby we may gather this, that there is but one third part of that Aire we draw into the heart in breathing, sent forth againe in the forme of vapour in expiration, because nature would have but one third part of the orifice to ly open for its passage out. Therefore the expiration or breathing out, and the *systole* of the heart and arteryes, is shorter than the inspiration, so that we may truly say, that the inspiration, or drawing the breath in, is equally so long as the expiration is together with the rest, which is in the midst between the two motions.

CHAP. XII.

Of the Distribution of the Vena arteriosa, and the Arteria venosa.

AVING hitherto shewed the originall of each of the vessels of the Heart, we must now speake of their distribution. The *Vena arteriosa*, or the arterious veine, and the *arteria venosa* or the *veinous arterie* each proceeding out of his proper ventricle, that is, the right and left, are divided into two large branches; one of which goes to the right and the other to the left hand, the one lying crosse wayes over the other, the veine alwaies riding over the arterye, as you may understand better by the sight of your eyes, than by reading of bookes. These branches at their entrance of the lungs are divided into two other large branches, and each of them goe to his peculiar Lobe of the lungs; and these againe runne almost into infinite other branches, dispersed in three places over the Lungs.

The Artery
alwaies lyes
under the
veins.

These vessels have acquired their names by reason of that transmutation of consistence, whereby the composure of a veine degenerates into an arterye, and that of an arterye into a veine, for the commodity of life. For this is a miracle of prudent nature to change the coats of the vessels of the lungs; producing a veine which in its body should imitate an arterye, and an arterye which should represent a veine: For if the *vena arteriosa* should have retained its proper consistence, the arterious blood which is carried by it from the heart to nourish the lungs, might by reason of its subtilty penetrate through, and flow away by reason of the rarity of the *veinous texture*; and so nature should never have attained her conceived end, that is, to nourish the Lungs, by reason of the continuall motion of their contraction and dilatation.

A twofold
reason why
the veine was
made Arterious,
or like an
Artery.

For nourishment cannot be assimilated to the part, unlesse it be put and cleave to it. Wherefor it was fit, that nature should make the body of this veine solid, that it might be immoveable, unshaken and stubborn (in respect of a veine which by its softnesse would have been too obsequious and yeilding to the agitation of the Lungs) that so it might have nourishment, which might be diffused into all parts thereof, and which might neither bee drawne by its *Diastole*, nor driven back into the heart by its *systole*. But the arterye hath the consistence of a veine, that by that *veinous softnesse* according to the necessity of nature it might be the more readily contracted and dilated, to bring the Aire in and carry the vapours forth of the heart. Here wee meet with a difficulty, which is, by what way the blood is carried out of the right into the left ventricle of the heart.

Why the Artery
was made
like a veine,

Galen thinks that there be certaine holes in the partition made for that purpose, and verily there are such, but they are not perforated. Wherefore Columbus hath found out a new way, which is, that the blood is carried to the lungs by the *vena arteriosa*, and there attenuated; and carried from thence together with the aire by the *Arteria venosa* to the left ventricle of the heart; this he writes truly very probably. Botallus in his treatise *De Catarrho* hath found out a third way, to wit a veine, which he calls *Arteriarum nutritrix*, that is, The nurse of the Arteries, which creepes a litle above the Coronall to the right eare of the Heart, and then goes into the left eare thereof. But yet I am very much afraid, that this veine observed by Botallus, is that vessel observed by Fallopius, whereby the *Vena arterialis* is joined to the Aorta, &c. by which all the vitall blood is carried for the forming and nourishment of the lungs whilest

By what way
blood may
passe out of the
right into the
left ventricle,

The veine called
the nurse
of the Arteries

Fallopius
called Arteria
nutritrix.

Gal. lib. 15 de usu part. cap. 6. whilest the infant is yet in the wombe. Of which also *Galen* makes mention, but it had laine hid from his time to this day, but that *Fallopins* raised up the memory of it againe.

CHAP. XIII.

The distribution of the ascendent Hollow veine.

Gal. lib. 15 de form. fetus.

The greater descendent branch of the hollow veine.

The upper branch of the hollow veine is the lesse.

Vena phrenica Coronalis.

Vena Arteriosa

Vena Azygos, or sine pari.

Cervicalis.

Musculosa.

In what place cupping glasses may be applyed in a bastard Pleurisie.

He Hollow veine rising out of the gibbous part of the Liver, and resembling (according to *Galen*) the body of a tree, is divided into two notable branches, but not of a like bignes. For the greater, by the hind part of the Liver upon the back bone and by the way, receives certaine other branches from the substance of the Liver which entred not into the great trunk with the rest. You may often see this descendent branch even to the backe bone upon which it lyes in this its descent, covered with the substance of the liver, so that it may seeme that branch proceeds not from that common trunk together with the ascendant, although indeed it alwayes doth. But the lesser branch ascends to the upper parts, and is distributed after this manner following. For first arising into the midriffe it bestowes two small veines upon it, on each side one, which from that part are called *Phrenica*. But from thence when it arrives at the right Eare of the Heart, it makes the *Coronales*, the Coronall or Crowne veines, which compasse the basis of the heart in manner of a Crowne. Thirdly entring somewhat more deeply into its right Eare, in its greater part it produces the *vena arteriosa*. Fourthly lifted up above the heart, on the right side it produces the veine *Azygos* or *sine pari* (that is, without a fellow) which descending to the fourth rib, (reckoning from above downwards) nourisheth the intercostall muscles and also the membranes of the 8 lower ribs, on both sides, sending a branch into each of the muscles at the lower part of the rib, which may bee sufficient for their nourishment. Besides also oftentimes, especially in little men, this veine *Azygos* nourishes all the spaces between all the ribs by the like branches, which it sends in the same manner to the foure upper ribs. Moreover also this *Azygos* sometimes, though but seldome, is found double, that is, on each side one. Here you must chiefly observe, that this veine after it hath nourished the spaces between the lower ribs, in its remainder descends under the *Diaphragma* and is joined on the left side to the Emulgent vein; by which it is manifest how an Abscesse, may be critically evacuated by the urine, in a pleurisy. But this same *Azygos* is more depressed on the right side, and meets with the *Vena lumbares*, but especially with one of them, which goes downe to the thigh, whereby *Fallopins* gathers that it is very convenient in the beginnings of Pleurisy to open the *vena poplitea*, the veine of the Ham. Fifthly above the *Azygos* (when it is wanting there) it sends forth the branch called *Intercostalis* to the other spaces between the upper ribs; although this is sometimes seene to come from the *Axillares*, which *Sylvius* calls the *subclavia*. Sixtly it brings forth the *Mammaria* so called, because in their greater part they run to the dugs between the fourth and fifth ribs, for the uses formerly mentioned; men and women have on each side one of these coming from the *Subclavia*: They are sometimes found to proceed by a certaine common orifice from the hollow veine, before it be divided into the *Subclavian* branches, but it is rather in beasts than in men; these veines descending by the sides of the *sternon* yeild nourishment to the 2 inner muscles of the chest, to the 7 intercostall muscles of the true ribs, to the *sternon* it selfe and to its ligaments and gristles, as also to the *Mediastinum* and the upper part of the right muscles, and the adjacent parts. Seaventhly it produces the *Cervicalis* which on both sides through the holes of the productions of the *Vertebra's* of the necke, ascends to the head, sending many small branches into the spinall marrow through the holes by which the nerves passe, and also into the membranes, ligaments, gristles, bones, and neighbouring muscles. Eightly the *Musculosa* or musculous, which also arising out of the *Subclavia* is divided into two other branches; the one whereof goeth upon the brest to the paps, nourishing the foremost muscles; wherefore in a bastard pleurisie Cupping glasses may be fitly applied in this place.

The other branch descends to the upper muscles of the chest, but specially to that which is called *Latisimus*. The tenth is the *Axillaris*. The eleventh the *Humeralis*, of which we will treat in their place. The twelfth and last is the *Jugularis* properly so called, which is twofold, the internall and externall. The internall being the lesser doth presently on both sides from this very beginning ascend by the sides of the *Aspera Arteria* or weazon even to the mouth and skull, yeilding nourishment to the parts by which it passes, as to the next membranes and nerves. But when it comes to the *basis* of the *Cranium* it is divided into two branches, the greater whereof going back along the *basis* of the *Cranium* to the hind part thereof, sending a branch to the long muscle scituate upon the *œsophagus*, it enters the *Cranium* with the small *Carotides* through the hole of the nerves of the sixth conjugation, where they become one common vessell. The lesser sending a slippe to the organe of hearing by the hole called *Cacum* (or the blind) also enters the *Cranium* and is spent in the thicker *meninx* nere to the hole of the third and fourth conjugation of nerves. The externall Jugular veine being greater and fairer, most commonly simple, yet sometimes double, either presently at his beginning, or a little after, ascends superficially on both sides of the neck, between the broad muscle or fleshy pannicle, being there easie to be discerned, and other muscles scituate at the sides of the neck, into which as also into the skin it sends certaine branches for nourishment.

bones unto the loynes. *GG*, the lower intercostall veines, to the branches of the veine *Azygos*, which go unto the distances betwixt the ribs, & afford surcles unto the muscles which lye upon the ribs & the racke-bones, & the membranes of the chest. *H*, the division of the hollow vein into two subclavian trunks neare the Iugulum under the brest-bone. *II*, the subclavian branch tending on either side unto the arme; called by some *Axillaris*. *K*, the upper intercostall veine which commonly sendeth three slips unto the distances of the upper ribs, unto which the first intercostall veine sent no branches. *LL*, the descending mammary veine: this descendeth under the brest-bone unto the right muscles of the *Abdomen*, & affoordeth surcles to the distances of the gristles of the true ribs, to the Mediastinum, the muscles that lye upon the breast and the skin of the *Abdomen*. *M*, the coniunction of the mammary with the Epigastricke vein ascending about the navill under the right muscles. *N*, the veine of the necke called *Cervicalis*, ascending toward the Scull, which alloweth surcles to those muscles that lye upon the neck. *O*, the veine called *Muscula*, which is propagated with many surcles into the muscles that occupy the lower parts of the necke and the upper parts of the chest. *P*, *Thoracica superior*, the upper chest veine which goeth to the muscles lying upon the chest, to the skinn of that place and to the dugges. *Q*, the double *Scapularis* distributed into the hollow part of the shoulderblade and the neighbour muscles: so also betwixt *P* and *R*, sometimes small veines doe reach unto the glandules that are in the arme-holes. *R*, *Thoracica inferior* running downward along the sides of the chest, and especially distributed into the muscle of the arme called *Latissimus*. *S*, the inner Iugular veine which entreth into the Scull after it hath bestowed some surcles upon the rough artery. *T*, the externall Iugular veine. *V*, the division of this veine under the root of the eare. *X*, a branch of the externall Iugular which goeth into the inside of the mouth, and is diversly divided into the parts therein contained. *Y*, the exterior branch distributed near the *Fauces* into the muscles of the chops and the whole skinn of the head. *Z*, a portion of the branch, *y*, reaching unto the face. *a, a*, the veine of the fore-head. *a, a* portion of it creeping through the temples *a, ** a propagation that goeth unto the skin of the Nowle or *Occiput*. *a, a*, the veine called *Cephalica*, or the externall veine of the arme which others call *Humeraria*. *b*, *Muscula superior*, a propagation of the *Cephalica* veine which goeth unto the backward muscles of the necke. Betwixt *b*. and *d*. on the backside issueth a branch from the *Cephalica* which passeth unto the outside of the blade, and a portion thereof runneth betwixt the flesh and the skin. *d, d*, a veine from the *Cephalica* which attaineth unto the top of the shoulder, and is consumed into the muscle that elevateth or lifteth up the arme and into his skin. *e, e*, a small veine from the *Cephalica* dispersed through the skin and the muscles of the arme. *f*, the division of the *Cephalica* into three parts. *g*, the first branch runneth deep unto the muscles which arise out of the externall Protuberation of the arme. *h*, the second branch which goeth to make the median veine. *i, i*, the third branch running obliquely above the wand and the outside of the arme. *k*, from this branch certaine circles are divided into the skin, the chiefe whereof is marked with *k*. *l*, the third branch at the wrist which is joyned at *l*, with the branch of the *Basilica* marked with *x*. *m*, the *Basilica* which on the right hand is called *Hepatica*, on the left hand *Lienaris*. *n, o*, a branch of the *Basilica* going to the heads of the muscles of the cubit at *n*, and to the muscles themselves at *o*. *p*, a notable branch of the *Basilica* running obliquely, and bestowing surcles upon the muscles that issue from the externall protuberation. This branch descendeth together with the fourth nerve. *q*, division of the *Basilica* into two branches, and that is noted with *q*, is ever accompanied with an artery. *s*, a branch of this veine bestowed upon the skin of the arme. *t*, a branch of the *Basilica* which together with the branch of the *Cephalica* marked with *b*, makes the *mediana* or middle veine marked with *a*. *u*, a branch of the *Basilica* going to the inner head of the arme. *xx*, a branch issuing out of the former that creepeth along unto the wrist and toward the little finger conjoining it selfe with a branch of the *Cephalica*. *y*, A veine running out unto the skinn at the outside of the cubit. Upper *z*. A propagation issuing out of a branch of the *Basilica* marked with *t*. Lower *z*. A branch of the *Basilica* *x*, going to the in-side of the Arme. *a*, The *Median* or common veine, *b*, The partition of the Median veine above the wrist: This division should have beene made above *y*. *y*. The Externall branch

of the partition which goeth to the outside of the head. *a*, From which issueth a small branch to the inside. *b*, The internall branch under *a*, which toward the middle and the ring finger is especially disposed. *c*, The veine of the thumbe disperfed into the mounten or hillock, which is conjoynd with the branch noted with *d*. *e*, the trunk of the hollow veine from which issue branches unto the parts seated under the liver. *f*, The fatty veine called *Adiposa sinistra*, which goeth unto the fat of the kidnies. *g*, The two Emulgents which leade wheyey bloud unto the kidnies. *h*, the two spermatick veines leading the matter of the feede unto the testicles. *i*, the beginning of the bodden vessell called *vas varicosum*. *k*, the veines of the loynes called *Lumbares* which are sent in the knots or knees to the rackebones, to the marrow of the backe, to the muscles that lies upon the loines, and to the *Peritonaeum*. *l*, the bifurcation of the hollow veine into the Iliacke branches, which bifurcation is not unlike *a*. *m*, *Muscula superior*, a transverse branch going to the muscles of the *Abdomen*, and to the *Peritonaeum*. *n*, the division of the left Iliacke veine, into an inner branch at *p*, and an utter at *q*. *r*, *Muscula media* the utter propagation of the branch *p*, distributed through the muscles of the *coxa* and the skin of the buttocks. *s*, An inner propagation of the same branch *p* which goeth unto the holes of the holy bone. *t*, the veine called *Sacra*, which goeth to the upper holes of the holy bone. *u*, the veine *Hypogastrica* distributed to the bladder, to the muscles of the fundament, and the neck of the womb. *v*, A veine arising from the utter branch marked with *o* which is ioyned with some branches of the internall veine, neare the holes or perforations of the share bone. *w*, A veine which when it hath passed the share bone distributeth one branch into the cup of the *coxendix* and to the muscles of that place. *x*, Another small branch which runneth under the skinn at the inside of the thigh. *y*, The congresse or meeting of the foresaid veine, with a branch marked with char. *z*, and distributed into the legge. *1*, The *Epigastricke* veine, a propagation of the utter branch *o* perforating the *Peritonaeum*, whereto as also to the muscles of the *Abdomen*, and the skinn it offereth branches, the chiefe branch of this veine is joyned with the descending mammary above the navell at *M*. *Δ*, *Pudenda* an inner propagation of the branch *o*, running overthwart unto the privities. *Θ*, *Saphana* or the ancle veine or the inner branch of the crurall trunk, which creepeth through the inside of the legge under the skinn unto the tops of the toes. *Λ*, the first interior propagation of the *Saphana* offered to the groin. *Ξ*, The utter propagation thereof divided to the foreside or outside of the thigh. *Π*, The second propagation of the *Saphana* going to the first muscle of the legge. *Σ*, The third propagation of the *Saphana* going to the skinn of the whirlebone, and unto the hamme. *Ϛ*, The fourth propagation of the *Saphana* dispersing his muscles forward and backward. *ϛ*, Branches from this unto the foreside of the inner ankle, to the upper part of the foote, and to all the toes. *Ω*, *Ischias minor* called also *muscula interior*, the utter branch of the crurall trunk divided into the muscles of the *coxendix*, and to the skinn of that place. *1, 2*, And this also may be called *muscula*. *1*, the exterior and lesser which passeth into some muscles of the legge: *2*, the interior greater and deeper unto the muscles of the thigh. *3, 4*, The veine called *Poplitea*, made of two crurall veines divided under the knee. *5*, From this a furcle is reached upward unto the skinn of the thigh. *6*, But the greater part runnes by the bent of the knee under the skinn as farre as the heele. *7*, Also to the skinn of the outward ankle. *8*, The veine called *Suralis* or calfe veine, because it runneth unto the muscles that make the calfe of the legge. *9*, The division of the Surall veine into an exterior trunk *9*, and an interior *14, 10, 11*, The division of the exterior trunk under the knee into an externall branch, which along the brace attaineth unto the muscles of the foot *11*, and in internall. *12, 13, 12, 13*, Which descending along the outside of the legge to the upper part of the foote is cloven into divers branches, and in the backe of the foot mixeth it selfe with *Poplitea*, or the hamme veine *20, 14*, The interior branch of the Surall veine which runneth into the backside of the leg. *15*, A branch hereof descending to the inside of the heele and the great toe, and is divided into divers furcles. *17*, *Ischias maior* issuing out of the internall trunk at *14*, and running through the muscles of the calfe. *18*, A propagation hereof derived unto the upper part of the foot, & affording two furcles to every toe. *19*, the remain-

of the inner trunk 14, behind the inner ankle, approacheth to the bottome of the foote and is consumed into all the toes. 20, the commixtion of the veine *Poplitea* with the surall or calfe-branch at 13.

Where the external Iugular veine may be safely opened in inflammations of the parts of the mouth.

But when it arives to the basis of the lower part of the head, it is divided into more branches, one wherof is carried to the muscles of the bone *Hyois*, the *Larinx*, the tongue and the lower part of the tongue (in which place it is commonly opened in squinancies, and other inflammations of the mouth) and to the coate of the nose. Another is carried to the *Dura mater*, passing on both sides through a hole situate under the bone *mastoides*, and besides, ascending to the bone of the backe part of the scull, it comes obliquely to the upper part of the suture *lambdoides*, where these branches meeting together, passe into the reduplication of the *Dura mater*, deviding the fore-part of the braine, that so joined and united, they may make the *torcular*; the third ascendent is distributed upon the backe part and *basis* of the lower jaw, to the lippes, the sides of the nose, and the muscles thereof: and in like manner to the greater corner of the eyes, to the forehead and other parts of the face, and at length by meeting together of many branches, it makes in the forehead the veine which is called *vena recta* or *vena frontis*, that is, the forehead veine. The fourth, ascending by the glands behind the eares, after it hath sent forth many branches to them, is divided into two others, one whereof passing before, and the other behind the eare, are at length spent in the skinne of the head. The fifth and last wandring over all the lower part of the head, going to the backe part thereof, makes the *vena pupis*, which extended the length of the head by the sagitall suture, at the length goeth so farre, that it meets with the *vena frontis*, which meeting is the cause, that a veine opened in the forehead, is good in griefes of the hinder parts of the head, and so on the contrary. But wee must observe that in the *Cranium* of some, the *vena pupis* by one or more manifest passages sends some portion thereof to the inner part of the head, so that the *vena pupis* being opened may make revulsion of the matter which causeth the internall paines of the head.

Vena recta.

Vena pupis.

CHAP. XIII.

The distribution of the nerves, or sinewes of the sixth conjugation.

Three paire of nerves of the sixth conjugation.

Because the Distribution of the arteries cannot be well shewed, unlesse wee violate those nerves which are carried over the Chest, therefore before we shew the distribution of the arteries, we will as briefly as we can, prosecute the distribution of these nerves.

Now the sixth conjugation brings forth three paire of nerves; for passing out of the skull, as it comes downe to the Chest, it by the way sends forth some branches to certaine muscles of the necke, and to the three ascendant muscles of the *Larinx* on each side of the *Sternon* and upon the clavicles. Then the remainder descending into the Chest, is divided on each side into these three paire. The first paire makes the *Ramus costalis*. The second, the *Ramus recurrens*. The third paire, the *Ramus stomachicus*. The *Ramus costalis*, or costall branch is so called, because descending by the roots of the ribs, even to the holy bone, and joyning themselves to these which proceede from each of the *Vertebra's* of the spine, they are carried to all the naturall parts.

Ramus costalis.

Recurrens.

The *Recurrens*, or recurrent is also called, because as it were starting up from the chest, it runs upwards againe, but these two Recurrent nerves doe not run backe from the same place; but the right from below the artery, called by some the axillarie, by others Subclavian, and the left from beneath the great artery, descending to the naturall parts. But each of them on each side ascending along by the weazon, even to the *Larinx*, and then they insinuate themselves by the wings of the *Cartilago scutiformis*, and *Thyroides* into the proper muscles, which open and shut the *Larinx*.

An anatomical Axillarie.

By how much the nerves are nearer the originall, to wit, the braine, or spinall marrow,

marrow, they are by so much the softer. On the contrary, by how much they are further absent from their originall, they are so much the harder and stronger, which is the reason, that Nature would have these recurrent nerves to runne backe againe upwards, that so they might be the stronger to performe the motions of the muscles of the *Larinx*. But the *Stomachicus* or stomacke-branch is so called, because it descends to the stomacke or ventricle. For this branch descending on both sides by the sides of the gullet, sends many branches from it into the inner substance of the lungs, into the coate thereof, into the *Pericardium* and heart; and then comming into the upper orifice of the stomacke, it is spent in many branches, which folded after divers manners and wayes, chiefly makes that mouth or stomacke, which is the seate of the Animall appetite (as they terme it) and hunger, and the judger of things convenient or hurtfull for the stomacke. But from thence they are diversely disseminated over all the body of the ventricle.

Why nature would have the vocall nerves recurrent.
Ramus Stomachicus.

Moreover, the same branch sends forth some small branches to the liver and bladder of the gall, giving each part by the way, so much sense as should be sufficiently necessary for it. Here you must note, the stomacke branch descends on each side one, knit to the gullet, and by the way they divide themselves into two branches, each of which goes to the opposite side, that it may there joine it selfe to the nerve of that side. To which purpose the right is carried above the gullet, the left below it, so that these two stomaticke become foure, and againe these foure presently become two.

CHAP. XV.

The division of the Arteries.

THe Artery arising forth of the left ventricle of the heart, is presently (the two Coronall arteries being first spread over the substance of the heart) divided into two unequall branches. The greater whereof descends to the lower parts, being distributed, as we formerly mentioned in the third Booke, and 22. Chapter. The lesser ascending to the upper parts, is againe divided into two other unequall branches, the lesser of which ascending towards the left side, sends forth no artery from it, untill it arrive at the first rib of the Chest, where it produces the subclavian artery, which is distributed after the manner following.

The left branch of the ascendant artery is lesse then the right. The distribution of the left subclavian artery into the,

First, it produces the intercostall, and by it imparts life to the three intercostall muscles of the foure upper ribs, and to the neighbouring places.

1
Intercostalis,

Secondly, it brings forth the Mammillary branch, which is distributed as the Mammillary veine is.

2
Mammaria.

Thirdly, the *Cervicalis*, which ascends along the necke by the transverse productions to the *Dura mater*, being distributed as the *vena cervicalis* is.

3.
Cervicalis.

Fourthly, passing out of the Chest, from the backe part of the Chest, it sends forth the *musculosa*, whereby it gives life to the hinde muscles of the necke, even to the backe part of the head.

4
Musculosa.

Fifthly, having wholly left the Chest, it sends forth the two *Humeraria*, or shoulder arteries, the one whereof goes to the muscles of the hollow part of the shoulder blade, the other to the joint of the arme and the muscles situate there, and the gibbous part of the shoulder blade.

5
Humeraria duplex.

Sixthly and lastly, it produces the *Thoracica*, which also is twofold, for the one goes to the fore muscles of the Chest, the other to the *Latsissimus*, as we said of the veine, the remnant of it makes the *Axillaris* of that side.

6
Thoracica duplex.

The other greater branch likewise ascending by the right side, even to the first ribbe of the Chest, makes also the subclavian of that side, which besides those divisions it makes on this side, like those of the left side, hath also another which makes the right and left *Carotides* or sleepey arteries, which ascending undivided with a nerve of the sixth conjugation and the internal jugular veine, by the sides of the *Aspera Arteria* or windpipe, when they come to the *Pharinx*, they are divided on each side into two branches, the one internall, the other externall. The internall and greater

The distribution of the right subclavian Artery. The *Carotides*, or sleepey arteries. Their division. The distribution of the internall branch of the sleepey arteries,

ter is sent to the *Pharinx*, *Larinx* and tongue; then entering into the head by the long hole, and the backe part of the upper jaw, it sends many branches to the nose, eyes, the inside of the temporall muscles and to the *Crasa meninx*, or *Dura mater*: the remainder of this branch going by the side holes of the same, that it might there make the *Plexus admirabilis* as we see. And then it is spent upon the basis of the braine abundantly diffused over the *tenuis meninx* or *Pia mater*, and the membrane or *Plexus Choroides*. The externall or lesser branch of the sleepey arteries goes to the cheekes, the temples, and behind the eares; lastly, it sends a branch into the long muscle of the necke, with which the internall Iugular veine insinuates it selfe into the *Dura mater*, cutting by the hole of the nerves of the sixth conjugation.

To what parts
the externall
branch of the
sleepey artery
arrives,

T. the distribution of the upper and lower branches into the hand and the fingers V. the trunk of the great artery ascending to the *Iugulum*, and the division thereof in that place into X, Y, Z. X, the left *Carotis* or sleepey artery. Y, *Subclavian dextra* is divided into branches, as the right is divided. Z. *Carotis dextra*, called also *Apoplectica* and *Lithargica*. a, The division of the left *Carotis* in the chops. b, the exterior branch of that division going into the face, the temples, and behind the eares. c, the inner branch going to the throttle, the choppes and the tongue. d, the division hereof at the basis of the scull, into two branches which enter the *sinus* of the *Dura mater*. e, A propagation of the branch b, unto the muscles of the face. f, the distribution of the branch b, under the roote of the eare. g, the fore-branch hereof creeping up the temples. h, the backe branch running on the backside of the eare under the skinne. i, the trunk of the great artery, descending unto the spondels of the backe. kkk, the lower *Intercostall* arteries which goe unto the distances of the eight lower ribbes, from which are offered furcles to the marrow, and to the muscles that grow to the backe and to the Chest. l, the artery of the midriffe called *Phronica* or *Diaphragmatica*. ζ, *Mesenterica Superior*, but you must note that above ζ, the trunk of the *Cœliacall* artery is taken away, lest the multitude of letters in so small a Table should breed obscurities. η, θ, the right and left emulgents running from the *Aorta* or great artery unto the kidneies. ι, κ, κ, the spermaticall arteries on either side going to the testicles. λ, the lower *Mesentericall* artery on the left below μ, running especially into the Collicke gut on that side. μ, μ, the arteries called *Lumbares* which runne overthwart and like knees, affording furcles to the muscles that grow to the loynes, and to the *Peritoneum*. ν, the lower; *Muscula superior* running into the sides of the *Abdomen* and the muscles. νν, the byfurcation of the great artery into two *Iliacke* trunks, and at the sides, but somewhat inward are branches which make those that are called *Sacra*. T, the division of the left *Iliacke* trunk into an inner branch at ξ and an utter at φ. ξ, the inner *Iliacke* branch. ο, *Muscula inferior*, the utter propagation of the inner branch going unto the muscles which cover the branch bone and the *Coxendix*. ω, *Hypogastrica*, the inner propagation of the inner branch going to the bladder, the yard and the necke of the womb. φ, the umbilicall artery. ς, the remainder of the branch ξ, assuming an addition from the utter branch neere φ, and so falling through the hole of the share bone into the legge. τ, *Epigastrica*, it ascendeth upward unto the right muscle of the *Abdomen*, and about the navell is ioyned with the mammary artery. υ, *Pudenda*, it creepeth overthwart the share bone. φ, the *Crural* trunk without the *Peritoneum*. χ, *Muscula cruralis exterior*, going into the fore muscles of the thigh. ψ, *Muscula cruralis interior*, going unto the muscles of the inside of the thigh. ω, The conjunction of this arterie with the branches. T, *Poplitea*, going to the muscles on the backside of the thigh. ΔΔ, which communicateth small branches to the ioynt of the knee, and the muscles that make the calfe of the legge. φ, the division of the *Crural* artery under the hamme into three branches. λ, *Tibiaa exterior*, it accompanieth the brace-bone, and is consumed into the muscles. ζ, the chiefe part of the *crural* artery. ζ, the upper & backer *Tibiaa*. πφ, the lower and backer *Tibiaa* running unto the upper side of the foote at φ. φ, A propagation of the *crural* artery going to the inner and upper side of the foote, and sprinkling a branch unto the ankle. ς, A propagation unto the lower part of the foote which affordeth furcles to each toe.

But we must note that there be more veines in a mans body, than arteries, and besides that the veines are farre thicker. For there is no need for preserving the native heat in the parts themselves, either of so many, or so large instruments of that kinde. Therefore you may often finde veines without arteries, but never arteries without veines.

But we understand that an artery is a companiou to a vein, not only when it touches it, or adheres to it by common membranes, as usually it happens; but also when it is appointed together with the veine for the use of the same part.

CHAP. XVI.

Of the Thymus.

What the
Thymus is.

The use.

The magni-
tude.

The *Thymus* is a glandule of a soft, rare, and spongy substance, of large bignesse, situate in the furthest and highest part of the Chest, amongst the divisions of the subclavian or Iugular veines and arteries, as yet contained in the Chest, for this use; that it might serve these vessels for a defence against the bony hardnesse of the Chest, and besides, that as it were by this prop or stay, the distributions of these vessels might become the stronger; for so we see that nature hath provided for others, especially such as are the more noble and worthy. This glandule appears very large in beasts and young men, but in such as have attained to full growth it is much lesse, and scarce to be seene.

CHAP. XVII.

Of the Aspera Arteria, the rough Arterie or Weazon.

The substance

The *Aspera Arteria* or Weazon seeing it is the instrument of voice and respiration, is of a gristly, ligamentous, and wholly various substance. For if it had beene one rough, and continued body with the *Larinx* or throttle, it could be neither dilated, nor compressed; opened, nor shut, neither could it order the voice according to our desire.

Composure.

It is composed of veines from the internall Iugular, of arteries arising from the *Carotides*, and of nerves proceeding from the Recurrent branch, of a double membrane, of which the externall comes from the *Peritoneum*; the internall, which is the stronger and woven with right fibers, from the inner coate of the mouth, the which is common with the inner coate of the *oesophagus* or gullet. And also it consists of round gristles, yet not drawne into a perfect circle, composed in manner of a channell, and mutually joined together in order, by the ligaments that proceede from their sides and ends.

Why the back
part of the
weazon is
ligamentous.

These same ligaments perfect the remnant of the circle of this *Aspera Arteria*, on that part next the gullet; which is thought to be done to this end; that that softnesse of a ligament, might then give place, when wee swallow harder and greater gobbets of meate. Of the two sorts of ligaments which are annexed to the gristles of the weazon, some tie and fasten together the rings or circles, which give meanes both to it, and these circles to be drawne out in length; other some bring these gristles into a perfect circle, which also yeeld them meanes of dilatation. These ligaments cover the inner superficies, but the gristles are placed without, to resist the incursion of externall injuries. But wee must note, that by this communion of the inner coates of the weazon and gullet, wee reape this benefit in the commodiousnesse of the action, that one of these parts being depressed, the other is lifted up, like a rope running in a wheele or pully. For thus whilest the gullet is deprest to swallow any thing, the weazon is lifted up; and on the contrary when the stomacke rises up in vomiting, the weazon is deprest. It is onely one, and that seated betweene the *Larinx* (from which it takes its beginning) and the lunges in which it ends; first dividing it selfe into two large branches, the right and the left, and besides each of these entring into the substance of the lunges, is againe divided into two others; to each of the Lobes one; and to conclude, these be subdivided into infinite others, through the substance of the Lobes.

Why the fore-
part is gristle-
ly.The number
and site.
The division
of the weazon
through the
Lobes of the
Lungs.

All these branches are gristly even to the ends. They are situate betweene the ends of the *Arteria venosa*, and the *Vena arteriosa*, that the entrance of the aire into the heart by the *arteria venosa* might be speedier, as also the passage out of the vapour, by the *vena arteriosa*. Thus it hath connexion with these in the ends, or utmost parts thereof, but by the other parts compassing it, with the members from whence it takes

takes them. The temperament thereof is cold and drie. The action is to carry the aire to, and vapours from the lungs; that by dilating, but this by pressing the gristles together. The temper and action.

CHAP. XVIII.

Of the Gullet.

THe *Oesophagus*, or Gullet which is the passage of the meat and drinke, The substance is of a middle substance betweene the flesh and sinewes, because it consists of one nervous membrane and another fleshy. The nervous is placed the innermost, and is continued to the inner Coate of the mouth even to the Lipps (whereby it comes to passe,) that the Lipps tremble in diseases which are ready to be judged by a critically vomiting and to the inner part Attractive force thereof of the *Aspera Arteria*; it consists of right Fibers for the attraction of the meat, which we see is sometimes so quicke and forcible in hungry people, that they have scarce time to chew it, before they find it, to be pluckt downe, as it were with a hand. The fleshy Coate placed without is woven with transverse fibers, to hasten The composition the ture,

time.

the going of the meat into the stomacke, and for expulsion in vomiting and breaking of winde. These two coats are continued with the two coats of the stomacke, and have the like fire. Besides, the Gullet hath these parts composing it, as a veine from the Gate and Hollow ascendent veine, a nerve from the sixth conjugation, an Artery from that which creeps alongst the bottome of the stomacke with the *vena Gastrica*, or else from the Arteryes ascending the hollow part thereof; but also besides all these vessels it may have a third coat from the membrane investing the Ribs, or *Pleura*. The magnitude of the Gullet is large enough, yet some be bigger, some lesse according to the variety of bodyes. The figure of it is round, that so it might be more large to swallow meat, and lesse subject to offence. It is placed between the backe bone and the weazon from the roots of the tongue even to the stomacke. But as it discends alongst the backe bone, when it comes to the fourth *Vertebra* of the Chest, it turnes to the right side, to give way to the great Artery *Aorta* and the descendent Artery, then it turnes to the left side to the stomacke, or mouth of the *ventricle*. Nature hath fastened it to the *Diaphragma* with strong membranous tyes, lest that, if it had laine upon the Artery it should have hindred the passage of the vitall spirit to the lower parts. It is onely one and that tyed to the forementioned parts, both by its vessels and membranes. It is of temper rather cold than hot, as all those parts, which are more nervous than fleshy, are. The Action thereof is to draw and carry downe the meat, and to cast forth such things by vomit as trouble the stomacke. Here you must note, that whilest we swallow downe, the Gullet is drawne downewards, and the weazon upwards, which is the cause that wee cannot sup and blow, swallow and breathe together at the same instant, which wee must thinke to happen by Gods singular providence; to whose name be glory for everlasting, Amen.

The End of the fourth Booke.

THE

THE
FIFTH BOOKE
OF THE ANIMALL
parts contained in the Head.

CHAP. I.

A Generall description of the Head.

Aving hitherto declared two generall parts of mans body, that is, the Naturall and vitall, it is now fit to betake our selves to the last, that is, the Animall, beginning with the head.

Whrefore we will first define the head, then divide it into its parts; thirdly describe each of these parts; fourthly demonstrate them after the order they offer themselves to our sight in dissection.

The head therefore is the seat of the senses, the Pallace and habitation of reason and wisedome, from whence as from a fountaine infinite actions and commodities arise. It is seated above the rest of the body, that the Animall spirit from thence, as from a tower, may governe and moderate the whole body, and performe all actions according to the præscript of nature. By the head we understand all that which is contained from the Crowne of the head to the first *vertebra* of the neck.

What the head is.

Why seated in the highest place.

The best figure of the head is round, lightly flatted on each side, extuberating something to the fore and hinde part thereof. For from hence is taken an argument of the goodnesse of the senses; on the contrary, those which are exactly round, or acuminate, and sharp towards the top, are not thought good. The head is devided into the face, forehead, temples, the forepart, the crowne and hinde part.

The figure.

The division thereof.

By the face we understand, whatsoever is contained between the Eye-browes and the lower part of the chin. By the forehead, all the space from the eye-browes even to the Coronall suture. By the temples, whatsoever is hollowed from the lesser Corner of the eye, even to the eares. By the forepart of the head, whatsoever runnes in length from the top of the forehead, or the Coronall suture, even to the suture *lambdoides*, and on each side to the *Ossa petrosa*, the stony bones, or scaly sutures. By the Crowne we signifie a certaine point exquisitely in the midst of the Sagittall suture, which is sufficiently knowne. By the *Occipus* or hindepart of the head, that which is terminated by the suture *lambdoides*, and the first *vertebra* of the neck.

Of all these parts there be some simple, some compound, besides some are containing

The containing
parts of the
head.

aining, some contained. Of the containing some are common to all the parts of the head, as the skinne, the fleshy pannicle and *pericranium*; others are proper to certaine parts, as the fleshy panicle to the neck, face, forehead, and skin covering the *Cranium*, the common coat of the muscles to the fat and face; The skull and both the *Meninges* to the braine.

The parts
contained.

The parts contained are the substance of the braine, the foure ventricles, and the bodyes contained in them, the nerves, the mamillary processes, the *Plexus Choroides* or *Retē Admirabile*, the *Glandula Basilaris*, and others of which we will speak hereafter.

Wee must now speak of the containing parts beginning with the skinne; for the order of teaching requires that we take our *Exordium* from the more simple, but first we will say some thing of the haire.

What the
haire is.

The haire is nothing els than an excrement generated and formed of the more grosse and terrene portion of the superfluities of the third concoction, which could not be wasted by insensible transpiration. The benefite of it is, that consuming the grosse and fuliginous or sooty excrements of the braine it becomes a cover and ornament for the head.

The use there-
of.

This haire of the head and eye-browes have their originall from the first conformation of the infant in the wombe, the rest of the haire of the body arise and grow forth as the body growes and becomes more dry, of which sort are the haire which cover the Chin, armeholes, groines and other parts of our bodyes.

CHAP. II.

Of the musculous skinne of the Head, (commonly called the hairy scalpe) and of the Pericranium.

What the
hairy scalp is.
Its connexion.

* Our Author with *Fallopins* and *Laurentius* confounds the *pericranium* and *periostium*; but *Pesalius Bauhinn* and *Bartholinus* distinguish them making the *pericranium* thin and soft, and the *periostium* most thin and nervous, and of most exquisite sense.

Why the
wounds there-
of must not be
neglected.

The *Pericranium* and *periostium* of the same nature. Whence all the membranes proceed.

Why when
any mem-
branous part
is hurt in any
part of the
body, the head
is affected by
consent.

The use of the
Pericranium.

He skinne which covers the Scull, and is covered with the haire, is farre more fleshy, thick, hard and dry than any other part of the body, especially which wants haire. The skinne hath almost the like condition of quality as those parts have, which it doth simply cover, but is as it were lost in them, or growne into one with them, as in the lips and forehead with the fleshy pannicle, wherefore it is there called musculous; in other places it adheres to the gristles, as on the sides of the nosethrilles and corners of the Eyes, whereupon it is there called gristlely.

It hath connexion with the *Pericranium* because joined to it, it receives nerves from the first and second *vertebra* of the necke, and from the third conjugation of the braine which are disseminated through all its substance, whereby it comes to passe, that the wounds, contusions, and impostumes that happen in or upon this skinne, are not to be neglected.

The * *Pericranium* (but I suppose it should be the *Periostium*) is a most thin membrane, which next and immediately covers all the bones of the body, and this on the head is called by a peculiar name the *Pericranium* by reason of the excellency of the *Cranium* or skull, in other bones it is tearmed the *Periostium*. And as the *Pericranium* takes its originall from the *Crassa meninx* propagating it selfe by certaine strings or threds sent forth by the futures and holes of the skull, so all other membranes of the body have their originall either from this *Pericranium*, or the *Crassa meninx*, lending forth their productions, as well by the holes or passages of the head, as by these of the spinall marrow or back bone it selfe, even to the Holy bone.

Of which this is an argument, for in what part soever of the body a membrane is hurt, presently the hurt or sense thereof comes to the *Crassa meninx*. For so those who have but their litle Toe hurt when they sneeze, or cough, perceive an increase of their paine, by the passage thereof to the braine.

The vse of this *Pericranium* is to cover the skull, and to give notice of things hurtfull, by the power of the quick sense which it is endued withall, and the *Periostium* doth the like in other bones. Besides it sustaines and fastens by the futures the *Crassa meninx* to the skull, least it should fall by reason of its weight upon the *Pia mater*, and so

to hurt it, and hinder the pullation of the braine and arteryes that are plenteously spread through both the *Meninges*. Wherefore the *Pericranium* hath most strait connexion with the *Crasa meninx*, because it takes the originall from thence.

We must thinke the same of the other membranes of the body, which thing is very notable in the solution of the continuity of the membranes.

CHAP. III.

Of the Sutures.

The Sutures do sew or fasten together the bones of the skull; these be 5 in number. Three are true and legitimate, two false and spurious. The Coronal, the first of the true sutures, is seated in the forepart of the head, descending downwards overtwhart the forepart of the head to the midst of the temples; it is so called, because *Corolla*, that is, wreaths, crownes or garlands, are set upon that place.

Their use and number.

The second is called the *Sagittalis*, or right suture, as that which running through the crowne devides the head into two equall parts, as with a straigh line, running the length of it from the Coronall to the *Lambdoides* or hinde suture.

But this third suture *Lambdoides*, is so called because it represents this Capitall greek letter Lambda, Λ . You must understand this description of the sutures, nor as alwaies but as for the greater part to be thus. For there be some skulls that want the foremost suture, other some the hind, & somtimes such as have none of the true sutures, but only the false & spurious. But also you shal somtimes find the Sagittal to run to the nose.

Some skulls want Sutures.

And oft times there be three or foure sutures in the backe part of the head, so that indeed the number of the sutures is not certaine. Which also we find observed by *Cornelius Celsus*, where he writes, that *Hippocrates* was deceived by the sutures by chance, for that he conjectured that the bones of the backe part of the head, were broken, becaule his Probe thrust to the roughnes of the second suture *Lambdoides*, staied as at a Cleft made in the bone by a stroake.

Cels. lib. 8. Cap. 4.

The other two are called the false, stony and scaly sutures, by reason they are made by a scaly conjunction of the bones; but not by a toothed saw or combe-like connexion. But if any aske, why the head consists not of one bone, that so it might be the stronger: I answer it is, that so it might be the safer both from internall and externall injuries. For the skull being as it were the tunnel of the chymney of this humane fabrick, to which all the smoky vapours of the whole body ascend, if it had beene composed of one bone, these vapours should have had no passage fourth.

Why the skull consists of divers bones.

Wherefore the grosser vapours passe away by the sutures, but the more subtile by the pores of the skull; some have their sutures very open, but others on the contrary very close.

Therefore nature hath otherwise compendiously provided for such as want sutures; For it hath made one or two holes, some two fingers bredth from the *Lambdoides*, through which the *Vena papis* enters into the skull, and they are of that largenes that you may put a points ragge into them, that so the vapours may have free passage forth, otherwise there would be danger of death; thus nature hath beene careful to provide for man against internall injuries; and in like manner against externall, for it hath made the head to consist of diverse bones, that when one bone is broken the other may be safe, the violence of the stroak being stayed in the division of the bones.

In what bodies and by what meanes the *vena papis* sometimes enters into the pores within the skull.

Whereby you may know, that if the skull chance to be broken in the opposite side to that which received the blow, that it happens either by reason of the defect of Sutures, or else because they are unperfect, and too firmly closed; otherwise it is impossible such fractures should happen by reason of the separation of the bones, which breakes the violence of the blow that it can goe no further.

In what men one part of the head being striken, the opposite is broken.

And certainly as it is rare to find a skull without Sutures, so it is rare to find such kinde of fractures. Therefore Chirurgions must diligently observe the Sutures and site of them, least they bee deceived and take them for fractures, or unawares apply a

Why we must
not apply a
Trepan to the
Sutures.

Trepan to them, whence by breaking the veines, arteryes and nervous fibers by which the internall parts communicate with the externall, there may ensue increase of paine, a violent defluxion of blood upon the *Crassa meninx*, and the falling thereof upon the braine, (the fibers being broken by which it stuck to the *Pericranium*) and so consequently a deadly interception of the pulsation of the Braine.

CHAP. IIII.

Of the Cranium, or Skull.

What the *Cranium* or skull is.

Why the
nowle bone
is harder than
the rest.

* My Author
means by the
Os Basilare in
this place the
wedge bone:
but some
Anatomists
make it a *Syn-
noma* of this
Os occipitis.
The fore-head
bone, next to
the nowle
bone is harder
than the rest.
A Cavity to
be observed in
the forehead
bone.

The *Cranium*, or Skull covering the braine like an Helmet, is composed and consists of seaven bones, of which some are more dense, thick and hard than other some. The First is the *Os occipitis*, or Nowle bone seated in the back part of the head, more hard and thicke than the rest, because we want

hands and eyes behind, whereby we may keep or save our selves from falling. This bone is circumscribed, or bounded by the future *Lambdoides*, and the * *Os basilare*. The eminencies and as it were heads of this bone are received into the first *vertebra*; for upon this the head is turned forwards and backwards, by the force of foureteene muscles and strong ligaments, which firmly tye these heads of the Nowle bone in the cavities of this first *vertebra*.

The Second bone of the skull is in the forepart, and is called the *Os coronale* or *Os frontis* the forehead bone, it hath the second place in strength and thicknesse. It is bounded by the Coronal suture, and the ends of the wedgebone in this forehead bone there is often found a great cavity under the upper part of the eye-browes, filled with a glutinous, grosse, viscid and white matter or substance, which is thought to helpe to elaborate the aire for the sense of smelling.

Chirurgions must take speciall notice of this cavity, because when the head chances to be broken in that place, it may happen, that the fracture exceeds not the first table; wherefore they being ignorant of this cavity, and moved with a false perswasion that they see the braine, they may thinke the bone wholly broken, and to presse the *Meninges*, whereupon they will dilate the wound, apply a Trepan and other instruments to lift up the second table of the bone, without any need at all, and with the manifest danger of the life of the patient.

Ossa parietalia
and *bregmatica*.

The third and fourth bones of the Skull are the *Ossa parietalia*, or *Bregmatica*, having the third place of density and thicknes; although this density and thicknes be different in diverse places of them. For on the upper part of the head, or crowne, (where that substance turnes not to a bone in children untill they have all their teeth, so that it feelles soft in touching, and through it you may feele the beating of the braine) these bones are very tender, so that oft times, they are no thicker than ones naile, that so the moist and vapourous excrements of the braine, shut up where the greater portion of the braine resides, may have a freer passage by the Braines *Diastole* and *Systole*. These two square bones are bounded above with the Sagittall suture, below with the scaly, on the forepart with the coronall, and on the hinde part with the *Lambdoides*.

Ossa petrosa, or
the scaly bones

The fifth and sixth bone of the skull are the two *Ossa petrosa* stony or scaly bones which are next to the former in strength. They are bounded with the false or bastard Suture, and with part of the *Lambdoides*, and wedgebone.

Os sphenoides,
or the wedge
bone.

The seaventh is the *Os sphenoides*, *basilare* or *Cuneiforme* that is, the wedgebone. It is called *Basilare*, because it is as it were the Basis of the head. To this the rest of the bones of the head are fitly fastened in their places. This bone is bounded on each side with the bones of the forehead, the stony bones, and bones of the Nowle and pallate. The figure represents a Batte, and its processes her wings.

Os Ethmoides
or *cribrosum*.

There is besides these another bone at the Basis of the forehead bone, into which the mamillary processes ead, the Greekes call it *ἰσχυρὸν*, the Latines *Cribrosum* and *Spongiosum*, the Spongy bone, because it hath many holes in it not perforated in a direct passage, as in a sieve, but winding and anfractuons, that the aire should not by the force of attraction presently leap or ascend into the braine, and affect it with its qualities,

qualities, before it be elaborated by its lingring in the way. There are besides also fixe other little bones lying hid in the stony bones, at the hole, or Auditory passage; on each side three, that is to say, the *Ineus* or Anvill, the *Malleolus* or Hammer, and the *Stapes* or stirrop, because in their figure they represent these three things; the use of these we will declare hereafter.

The three bones of the Auditory passage.

But also in some skulls there are found some divisions of bones, as it were collected fragments to the bignesse almost of ones thumbe, furnished and distinguished by their proper commissures, or sutures, which thing is very fit to be known to a Chyrurgion in the use of a Trepan.

Verily he may give a conjecture hereof, whilest he separates the *Pericranium* from the skull, for the *pericranium* is with greater difficulty pluckt away from the sutures, because the *Crasa meninx* hath straiter connexion therewith by his nervous fibers sent forth in such places. The Skulls in women are softer and thinner than in men, and in children more than in women, and in young men more then in men of a middle age. Also the *Æthiopians* or Blackamoors, as also all the people inhabiting to the South, have their sculles more hard and compos'd with fewer sutures.

By what meanes a Chirurgion may conjecture, that there are extraordinary sutures in certaine places of the skull. The skulls of such as inhabit the Southern countries are more hard and dense. We must observe the extraneous be- sides nature which are in some skulls.

Therefore as it is written by *Hippocrates*, such as have their Skulls the softer, the Symptomes in fractures are more dangerous and to be feared in them. But the skull by how much the softer it is, by so much it more easily and readily yeilds to the perforating Trepan. Moreover in some skulls, there bee bunches standing out besides nature, made either round, or cornered, which the Chirurgion must observe for two causes; the first is for the better consideration of a blow or fracture. For in these bunches, or knots, the solution of the continuity cannot be, if it seeme to be stretched in length, but that the wound must penetrate to the inner parts. For in a round body there can be no long wound; but it must be deepe, by the weapon forced the deeper; because as a round body touches a plaine but onely *in puncto* in a prick or point, so what-so-ever falls only lightly or superficially upon it, onely touches a point thereof. But on the contrary a long wound must be upon a plaine surface, which may be but only superficiall.

Another cause is, because such bunches change the figure and site of the Sutures. And the Chirurgion must note that the skulls hath two tables, in the midst whereof the *Diploe* is; which is a spongy substance into which many veines and arteryes & a certaine fleshynefle are inserted, that the skull should not be so heavy, and that it might have within it selfe provision for the life thereof; and lastly that there might be freer passage out for the fuliginous vapours of the braine.

The site and substance of the *Diploe*.

The upper table is thicker, denser, stronger and smoother than the lower. For this as it is the slenderer, so it is the more unequall, that it may give place to the internall veines and arteryes (which make a manifest impression into the second table on the inside thereof) from which branches enter into the skull by the holes which containe the eyes. Which thing fastens the *Crasa meninx* to the skull, and is therefore very worthy to be observed.

For in great contusions when no fracture or fissure appeares in the skull by reason of the great concussion or shaking of the braine, these vessels are often broken, whence happens a flux of blood between the skull and membranes, and lastly death. But it is fit the Chirurgion take good heed to the tender and soft substance of the *Diploe*, that when he comes to it, having passed the first table, he may carefully use his Trepan, least by leaning too hard, it run in too violently, and hurt the membranes lying underneath it, whence convulsion and death would follow. To which danger I have found a remedy, by the happy invention of a Trepan, as I will hereafter more at large declare in handling the wounds of the head.

There may be a deadly rupture of the vessels of the braine without any fracture of the skull. Caution to be had in the use of the Trepan.

CHAP. V.

Of the Meninges, that is, the two membranes called
Dura Mater and Pia Mater.

Why the bone
Ethmoides is
perforated.

The *Crassa meninx* is one of the first and principall membranes of the body; it goes forth by the sutures and the holes of the nerves that proceed out of the skull; and it passes forth by the bone *Ethmoides* perforated for that purpose, to carry smells to the Braine, and purge it of excrementitious humors. This same *Crassa meninx* invests the inner coate of the Nose; also it passes forth of the great hole through which the spinall marrow passes, vested with this *Crassa meninx*, with all the nerves and membranes. For which cause, if any membrane in the whole body be hurt, by reason of that continuation which it hath with the *Meninges*, it straight communicates the hurt to the head by consent.

The confi-
stence of the
Crassa meninx

The use,

The *Crassa meninx* is thicker and harder than all other membranes in the body; whereupon it hath got the name of the *Dura mater*, besides also it begirts, produces, and defends the other membranes.

What the
Torcular is.

One part of
the braine be-
ing hurt the
other keeps
the creature
alive.

The confi-
stence of the
Pia mater.

The sense of
the *Meninges*.

The use of it is to involve all the braine, and to keepe it when it is dilated, that it be not hurt by the hardnesse of the Scull. For the course of nature is such, that it alwayes places some third thing of a middle nature, betwixt two contraries. Also the *Crassa meninx*, yeelds another commodity, which is, that it carries the veines and arteryes entring the Scull for a long space. For they insinuate themselves into that part, where the duplicated or folded *Meninges* separate the braine from the *Cerebellum*, and so from thence they are led by the sides of the *Cerebellum*, untill they come, as it were, to the toppe thereof; where being united they insinuate themselves into that other part of the *Crassa meninx*, where in like manner being duplicated and doubled, it parts the braine at the top into the right and left; These united veines run in a direct passage even to the fore-head, after the manner of the Sagittal future; They have called this passage of the mutually infolded veines, the *Torcular*, or Presse, because the blood which nourishes the braine is pressed and drops from thence by the infinite mouthes of these small veines. Therefore also here is another use of the *Crassa meninx*, to distinguish the braine by its duplication, being it thrusts it selfe deepe into its body, into two parts, the fore and hind, and presently to separate the same into the right and left; that one part being hurt, the other may remaine safe and sound, performing its duty to the creature, as we see in some that have the Palsey. *Columbus* observed that this *Meninx* was double, and verily I have found it true by my owne sight.

The other *Meninx* or membrane of the braine, called *Pia mater*, is most slender interchased with divers veines and arteryes, for its owne and the braines nourishment and life. This doth not onely involve the Braine, as the *Crassa meninx* doth, but also more deeply penetrates into the anfractuons passages thereof, that it may every where joync and bind it to it selfe, not easily to be drawne from thence, by many small fibers whereby it descends even to the cavities of the ventricles thereof. Wherefore you must see it absolutely in the site as wee have mentioned, and not plucke it away unlesse with the substance of the Braine.

These membranes when they are hurt or afflicted, cause greivous and most bitter torment and paine; wherefore I dare say, that these membranes are rather the authors of sense than the braine it selfe, because in diseases of the Braine, as in the Lethargie, the party affected is troubled with litle or no sense of paine.

CHAP. VI.

Of the Braine.

Now followeth the Braine, the beginning of the nerves and voluntary motion, the instrument of the first and principall faculty of the Soule, that is, the Animall and Rationall. Man hath this part in greater plenty then any other Creature, for it almost fills the whole Scull. But if it should have filled it all, the Braine could not be moved, that is, dilated and contracted in the Scull. It is of a cold and moist Temperature. The laudible temper of the braine is knowne by the integrity and perfection of the internall and externall senses, the indifferency of sleepe and waking, the Maturity or ripenesse of judgment, and constancy of opinions, from which, unlesse it meet with better and more probable, it is not easie to be moved.

What the
braine is.

sing the braine. *FFF.* Certaine vessels running through the convolutions or branches of the braine. *GGG.* Certaine branches of veines running through the sides of the *dura meninx.* *HHH.* The thicke membrane reflected downeward.

You shall know the braine is more hott, by the quicknesse of the senses and motions of the body, by shortnesse of sleepe, the suddaine conceiving of opinions and change of them, by the slippery and failing memory, and lastly by easily receiving hurt from hot things, as the Sunne and Fire. Such as have a cold braine, are slow to learning, and to conceive other things, but they do not easily put away their once conceived opinions. They have slow motion to action, and are sleepy. Those who have a dry braine, are also slow to learne; for you shall not easily imprint any thing in dry bodyes, but they are most constant retainers of those things they have once learned; also the motions of their bodyes are quicke and nimble. Those who have a moist braine doe easily learne, but have an ill memory, for with like facility as they admit the species of things and imprint them in their minds, doe they suffer them to slide and slip out of it againe. So Clay doth easily admit what Character or impression soever you will, but the parts of this Clay which easily gave way to this impression, going together againe, mixes, obliterates and confounds the same. Therefore the senses proceeding from a cold braine are dull, the motions slow, the sleepe profound.

The Action.

Number.

The Action of the braine is to elaborate the Animall Spirit and necessary sense serving the whole body, and to subject it selfe as an instrument to the principall faculties, as to reason. The braine is twofold, the fore and hinde. The hinde by reason of its smallnesse is called the *Cerebellum*, (the litle or After-braine). But the fore by reason of its magnitude hath retained the absolute name of the braine. Againe this fore-braine is two-fold, the right and left, parted by that depression, which wee formerly mentioned, of the *Meninges* into the body of the braine. But this division is not to be here so absolutely taken, as though the Braine were exactly divided and separated into so many parts, but in the sense, as we say the Liver and Lungs are divided a pretty way, whereas at their *Basis* they have one continued body. The outward surface of the Braine is soft, but the inward hard, callous and very smooth; when on the contrary, the outward appeares indented and unequall with many windings, and crested as it were with many wormlike foldings.

CHAP. VII.

Of the ventricles and mamillary processes of the Braine.

The substance of the braine is porous and sweats forth blood.

The foure ventricles thereof.

The magnitude of the upper ventricles of the braine.

Or the easie demonstration of the ventricles of the braine, it is convenient you cut away a large portion thereof, and in your cutting observe the blood sweating out of the pores of it. But besides, it is fit you consider the spongy substance by which the excrements of the braine are heaped up, to be presently strained out, and sent away by the hollow passage. In the substance of the braine you must observe 4 ventricles, mutually conjoined by certaine passages, by which the spirits endued with the *species* of things sensible, may goe from one into another. The first and two greater, one on each side are placed in the upper braine. The third is under them in the middle part of the braine. The fourth and last at the fore side of the *Cerebellum*, towards the beginning of the spinall marrow. The two formost are extended the length way of the braine in the forme of a semicircle, whose hornes looke or bend outwards. They are spacious and large, because it was meet the Spirits contained there together with their excrements, should be there purified and clenfed; but in other ventricles, the pure and already elaborate spirits are onely received. These ventricles are white and smooth in their inner superficies; but that on each side they have an extuberancy at the midst of the semicircle, situate at the

basis

basis of the Pillar of the middle ventricle towards the nose under the *Septum lucidum* or cleere partition, severing or parting in sunder these two ventricles.

This *Septum lucidum*, or cleere or thin partition, is nothing else than a portion of the braine indifferently solide, but very cleere, that so through this partition the animall spirits contained in these two ventricles may mutually passe and bee communicated, and yet no other grosser substance may pierce the thin density thereof.

Wherefore it is not to be feared, that the water contained in one of the ventricles may passe to the other through this partitiō, as I have oft times observed to the great admiration of the spectators in the dead bodies of such as dyed of the Palsy, in which I have found the ventricle of that side which was taken with the palsy much dilated, according to the quantity of the water contained therein, the other being either wholly empty and without any; or certainly no fuller than in any other, dead through any other occasion. For some affirme that there is a certaine kind of waterish moisture alwaies to be found in the ventricles, which may be made by the condensation of the Animall spirits by the force of the deadly cold. But these two first ventricles of the braine goe into one common passage, as both the bellowes of a fornace, whereby the spirit instructed with the species of things goes into the under, or middle ventricle from the former. In these same first ventricles the *Plexus Choroides* is to be considered, and in like manner the passage by which the grosser excrements are driven or sent into the pituitary Glandule.

The *Septum Lucidum*.

Why the Palsie of one side is not presently communicated to the other.

The Third Figure represents the Cerebellum with the wormy processes separated from it.

AB, The right and left part of the After-braine.

CD, The anterior and posterior regions of the middle part of the After-braine.

E, The anterior wormy processe.

F, The posterior wormy processe.

GG, In this place the After-braine did grow to

the spinall marrow. H, The cavity in the spinall marrow maketh the fourth ventricle. IK, The anterior and posterior processes of the braine, called *vermi-formes* or the wormy processes.

This *Plexus Choroides* is nothing else, but a production of the *Pia mater* diversly folded with the mutuall implication of veines and arteryes woven in the forme of a net. These vessels are of magnitude and capacity sufficient, both to yeild life and nourishment to that part to which they are fastened, as also for the generation of the Animall spirits, as which take fit matter from the veines stretched fourth into this same *Plexus*, the hinde artery and veine *Torcular*, and also from the aire entring into the braine by the mamillary processes. But the mamillary processes are certaine common waies for conveyance of the aire and smells into the braine, and carrying of excrements from the braine.

The *Plexus Choroides*.

For thus in them who have the Catarrhe and *Coriza* or pose, neither the aire, nor smells can penetrate into the braine; whence frequent sneezings ensue, the braine strongly moving it selfe to the expulsion of that which is troublesome to it. But of the excrements of the braine, whether bred there, or proceeding from some other part, some are of a fumide and vaporious nature which breathe insensibly through the Sutures of the skull; Others are grosse and viscid, of which a great part is expelled by

The *Processus Mamillares*.

The use of
the upper
ventricles of
the Braine.

by both these productions, or through each of them. For thus in the Pose you may see some who have one of their nostrils stop't, the other running, and some who have both obstructed. The most proper benefit of the two first ventricles of the braine is to entertaine the Phantasie as in a convenient seat and habitation, seeing the minde there estimates and disposes in order the species of things brought in from the externall senses, that so it may receive a true judgement of them from reason which resides in the middle ventricle.

The ~~last~~ of
the third ven-
tricle of the
braine.
The parts to
be considered
in it.

The third ventricle is seated betweene the hindermost extremities of the former ventricles, and the last ventricle of the *Cerebellum*. In this sixe parts present themselves to our consideration, that is the *Psalloides* or Arch, the *Conarium*, or pine Glandule, the Buttocks, wormelike productions, the Bason and passage which is from this middle into the last and hindemost ventricle. The *Psalloides* or arch is nothing els, but the cover of the middle ventricle, resembling a rooffe borne up with three stayes or pillars, the one whereof is extended to the nose under the *Septum lucidum*, the two other on each side one, looke towards the backe part of the braine. This is the reason of this figure which is outwardly convexe and inwardly concave, to wit, that there might be free space for that motion which the Animall spirit inwardly produces, and besides that it might more easily sustaine the burden of the braine lying upon it. For an arched figure is the most convenient of all other to sustaine a waight.

What the
formix or
Arch is, and
the use thereof.

What the
Conarium or
pine Glandule
is.

The *Conarium* or Pine glandule, is a small Glandule of the same substance with the braine, round and somewhat long, like a pine Apple, from whence it hath the name; this Glandule is seated over against a small hole which descends to the lowest ventricle. It hath this use, to strengthen the division of the vessells led thither with the production of the *Pia mater* for the generation of the animall spirits, and the life and nourishment of the braine.

What the
Nates or But-
tocks are.

The *Nates* or Buttocks are subjected or placed under this Glandule, that is, bodies of a solid and white substance drawne out in length like a childs buttocks, especially in beasts, and chiefly in a sheepe. These buttocks have such a solid substance, that so they may keepe open and free the passage, or channell that runnes downe from the middle to the lower ventricle, by meanes of which the Braine participates with the *Cerebellum*.

What the
Worme is.

The worme is a production of the *Cerebellum* or After-braine, to wit a portion of the same being in the top or beginning and as it were in the entrance thereof, being like many litle circles or wheelles mutually knit together by slender membranes; and it is so called because it resembles those thicke white wormes which are found in rotten wood. It doth as it were performe the office of a porter to the formerly mentioned passage, that it may give way and entrance into the *Cerebellum* to a necessary quantity of spirits, when need requires; lest that, if they should rush with a suddaine violence into the *Cerebellum*, they might confound the imprinted notions of things to be remembred.

Here the *Pel-
vis* or Bason
is confounded
with the
Tunnell.

The *Pelvis* or Bason is a passage appointed for the carrying away of the grosse excrements by the palate, and is so called because it hath the similitude and use of a bason or Tunnell; it descends from the third ventricle into the Glandule which is seated betweene the processe of the wedge-bone called the saddle thereof, as you may perceive by putting in a spatherne. Now there remains the last of the sixe parts proposed to our consideration in the third ventricle, that is, the Channell or passage running from this third ventricle into the fourth, for the use formerly mentioned.

The Channell
from the third
into the fourth
ventricle.

This Channell descending in its originall from the Bason, goes from thence under the buttocks into the last ventricle, the *Meninges* being perforated; which that you may shew, it is fit you put the end of a spatherne through it. The benefit of the third ventricle is; that it may be as a Tribunall or judgment seate to the Reasoning faculty, when the mind will draw conclusions from things seene.

The fourth
ventricle of
the Braine.

The fourth ventricle is seated in the place we formerly mentioned; it is lesse than the rest, but more solide; lesse as that which was not to receive the spirit before it was purified, and clemented from all impurities; but more solid that it might containe it the safer. The use therof is, to be as a Treasury and store-house of the opinion, and

and judgments which reason shall decree, that when neede requires, wee may fetch and draw them from thence as laid up in store. I know *Galen*, and the Greeke Physicians have not so distinguished in places the three fore-mentioned facultyes; but have written, that they all are all over confused through the whole substance of the braine, which opinion also *Fernelius* in his *Pathologia* hath renewed. Yet I had rather follow this opinion, as commonly received and celebrated by the Arabian Physicians.

The Mammillary processes are the instruments and passages of smelling, being of the same substance with the braine, and like nerves, which runne out from the hinder horns of the upper or foremost ventricles of the braine to the *Ethmoides* and spongy bones of the nose, that hence they may receive the divers kinds of smells, and carry them into the Braine. But although they be like nerves, yet they are not accounted nerves because they go not out of the scull.

The use of the Mammillary processes,

From *I* to *K*, A part of the third ventricle going to the fourth, under the Testicles.

KLMN, A part of the fourth ventricle which is engraven in the mar-

row. *O*, The top of the fourth venticle. *P*, The place where the spinall marrow goeth out of the skull. *Figure 11.* *AB*, Parts of the opticke nerves. *CD*, The sleepey arteries. *E*, The Bason or Tunnell hanging downe. *F*, A hole or perforation of the *dura meninx*, through which the Tunnell reacheth unto the glandule. *GG*, Parts of the second conjugation of sinnewes. *Figure 12.* *A*, The Glandule. *B*, The Bason or Tunnell called *Pelvis* or *Infundibulum*. *CDEF*, The foure holes thorough which the phlegmaticke excrement issueth.

CHAP. VIII.

Of the 7. conjugations of the Nerves of the Braine, so called, because they alwayes shew the Nerves conjoined and doubled, that, is on each side one.

What a Nerve
or Sinew is,

Yes substance.
Whether the
nerves have a
third mem-
brane from the
Ligaments of
the *Vertebra's*.

Their magni-
tude.
Their figure.

Their use.

Their number

The first con-
jugation of
nerves.

He nerves are the waies and instruments of the animall spirit and facultyes of which those spirits are the vehicles, as long as they are contained in the braine; they consist of the only and simple marrowey substance of the braine; or spinall marrow. But passing forth of the braine, they have another membranous substance which involves them joined with them from the two membranes of the braine; and according to the opinion of some Anatomists, they have also a third from the ligaments drawn as well from divers others, as from these by which they are tyed to the *Vertebra's*; Yet this opinion seemes absurd to me, seeing such a membrane, as that which is insensible, wholly repugnes the condition of a nerve, which is to give sense to the parts to which it is inserted.

The magnitude of the nerves is different, according to the divers necessity of sense incident to the parts into which they are inserted. Their figure is round, and long like to a conduit pipe to carry water in; the membranes of the braine, with which the nerves are covered, being dilated and stretched over them, after the same manner that the processes of the *Peritoneum* involves the spermatick vessels, with which they goe downe to the Testicles, and take life and nourishment by the capillary veines and arteryes, which descend to them with the membranes. They are made for this use, that they may impart sense to the sensitive parts, and motion to these that are fit to be moved. All the nerves descend from the braine either mediately, or immediately; their Number is seaven and thirty paire, or conjugations, whereof seaven have their originall immediately from the braine, the other thirty from the spinall marrow.

The first conjugation of the nerves of the braine is thicker than all the rest, and goes to the eyes, to carry the visive spirit to them. These ariseing from diverse parts of

of the braine, in the middle way before they goe out of the skull meet together crosse-wise like the Iron of a Mill (which is fastened in the upper stone) going into one common passage with their cavities not visible to the eye; that so the spirits brought by those two nerves may be communicated, and they are mutually joyned and meet together so, that being driven back from one eye they may flie backe into the other. An argument wherof may be drawn from such as aime at any thing, who shutting one of their eies, see more accurately; because the force of the neighbouring spirits united into one eye, is more strong than when it is dispersed into both. This conjugation when it comes into the glasse humour, is spent in the structure of the net-like coate which contains this humor on the backe part.

The second conjugation goes into many parts, at its passing forth of the skull, and in the bottome of the circle of the eye it is distributed into the seaven muscles moving the eyes.

The second conjugation.

The Seventh figure shewing the eight conjugations of the Nerves of the braine.

FIG. I.

FIG. II.

AA, 2. The braine.

BB 1, 2. The After-braine.

CC 1, 2, the swelling of the braine which some call the mammillary processes.

DD 1, the beginning of the spinall marrow out of the Basis of the braine.

EE 1, 2, a part of the spinall marrow when it is ready to issue out of the skull.

FF 1, 2, the mammillary processes which serve for the sense of Smelling.

GG 1, 2, the opticke nerves.

HH 1, the coition or union of the opticke nerves.

II 1, 2, the coate of the eye where into the optick nerves is extended.

KK 1, 2, the second paire of the sinews, ordained for the motion of the eyes.

LL 1, 2, the third paire of sinews; or according to the most Anatomists, the lesser roote of the third paire.

MM 1, 2, the fourth paire of sinews, or the greater roote of the third paire.

NN 2, a branch of the third conjugation derived to the musculous skin of the forehead.

OO 2, a branch of the same to the upper jaw.

PP 2, another into the coate of the nofethrils.

QQ 2, another into the temporall

muscles. RR 2, a branch of the fourth conjugation crumpled like the tendrill of a vine.

SS 2, a branch of the same reaching unto the upper teeth and the gummes.

TT 2, another of the same to the lower jaw.

VV 2, a Surcle of the branch T, to the lower lip.

XX 2, another surcle from the branch T, to the rootes of the lower teeth.

Q 2

YY 2,

rr 2, the assumption of the nerves of the fourth conjugation unto the coate of the tongue. *z* 1, 2, the fourth paire are vulgarly so called which are spent into the coats of the pallat. *a* 1, 2, the fift paire of sinewes which belong to the hearing. *φ*, the *Auditory* nerve spred abroad into the cavity of the stony bone. ***, a hard part of the fift conjugation above, the *** which may be counted for a distinct nerve. *b* 1, 2, a small branch derived from this harder part of the first paire. *c* 1, 2, a lower branch from the same originall. *d* 1, 2, this nerve is commonly ascribed to the fift paire, but indeed is a distinct conjugation which we will call the Eight, because we would not interrupt the order of other mens accounts. *e* 1, 2, the sixt paire of sinewes. *f* 2, a branch from them derived to the neck and the muscles couched thereupon. *g* 2, another branch to the muscles of the Larinx or throttle, *b* 1, 2, the seventh paire of sinewes. *i* 1, the union of the seventh paire with the sixt. *l* 2, a propagation of the seventh paire to those muscles which arise from the Appendix called *Styloides*. *m* 2, Surcles from the seventh conjugation to the muscles of the tongue, the bone *Hyois* and the Larinx. *opq* 1, three holes; through the hole *o* the phlegme yssueth out of the third ventricle of the braine to the Tunnell, and at *p q*, is the passage of the *Soporary* arteries to the ventricles of the Braine.

The third conjugation.

The third is two-fold, in the passage out of the skull it is like-wise divided into many branches, of which some are carryed to the temporall muscles, into the *Massetes* or Grinding muscles, into the skinne of the face, forehead and nose; Othersome are sent into the upper part of the cheek, and the parts belonging to it, as into the teeth, gummies and the muscles of the upper lippe; and those which are called the round which incomasse the mouth on the inside; the last are wasted in the coate of the tongue, to bestow upon it the sense of tasting.

The fourth conjugation.

The fourth conjugation is much smaller, and is almost wholly wasted upon the coate of the Pallate of the mouth, to endue it also with the sense of tasting.

The fift conjugation.

The fift at its originall and having not as yet passed forth of the skull, is divided into two, and sends the greater portion thereof to the hole of the eare, or passage of hearing, that it may support the auditory faculty; and it sends forth the other lesser portion thereof to the temporall muscles by the passage next to it; by which the second conjugation passes forth.

The sixt conjugation.

The sixt being the greatest next to the first, passing entire forth of the skull, imparts some small branches to certaine muscles of the neck and throttle, and then descending into the chest, it makes the recurrent nerves, and dispersed over all the parts of the two lower bellyes, it passes even to the bladder and testicles, as wee shewed in the former booke.

The seventh conjugation.

The seventh is inserted and spent upon the muscles of the bone *Hyois*, the tongue and some of the throttle, to give them motion; it passes forth of the skull by the hole of the nowle bone at the extuberancies thereof.

CHAP. IX.

Of the Rete Mirabile, or wonderfull Net, and of the Wedge-bone.

The existence of the Animall spirit.

What the Rete Mirabile is.

The site, and number.

He Animall spirit is made of the vitall, sent from the heart by the internall sleepey Arteryes to the braine. For it was requisite that it should be the more elaborate, because the action of the Animall is more excellent than that of the vitall; nature hath framed a texture of Arteryes in many places running crosse one another, in the forme of a Net diverse times doubled; (whereupon it had the name of the wonderfull Net) that so the spirit by longer delay in these Labyrinthean or maze-like turnings, might be more perfectly concocted and elaborate, and attaine to a greater fittesse to performe the Animall functions.

This wonderfull Net scituate at the sides of the *Apophyses clinoides* or productions of the wedgebone, is twofold; that is, divided by the pituitary Glandule which is scituate

scituate betweene the said *Apophyses Clinoides*, having the wedgebone lying under them, next to the *Craffa Meninx*, being perforated on the right and left side, next to which lye bones as rare as a sponge even to the Pallate, by which the Phlegme is purged by the mouth and nose; and therehence, I thinke, that spittle flowes, which such as have a moist braine, continually spit out of their mouth.

The Eight figure of the braine.

FIG. I.

A, The Braine.

B, The Cerebellum or after-braine.

C, A proceffe of the brain, but not that which is called *Mammillaris*.

DD, The marrow of the backe as it is yet within the skul.

E, The *Mammillary* proceffe or instrument of smelling.

F, The opticke nerve.

G, The coate of the eye into which the opticke nerve is spread.

H, The nerve that moveth the eye or the second payre:

I, The third conjugation, or the harder and lesser branch of the nerves of the third conjugation brought forward.

K, The fourth conjugation or the greater and thicker nerve of the third payre bending downward.

L, A branch of the nerve marked with I, which goeth to the fore-head.

M, A nother branch of the nerve I, reaching to the upper jaw, NN, A nerve proceeding from the branch I, intexed or woven with the coat of the nose. O, The nerve of the temporall muscle issuing from the branch I. P, A nerve contorted of the nerves K and b. Q, A nerve proceeding from the branch K, to the sockets of the upper teeth. R, A nerve creeping from the nerve K, to the lower jaw. S, A surcle of the branch R, offered to the lower lip. TT, Other surcles from the branch R, attaining to the lower teeth. VV, A branch of the nerve K, diffused into the coate of the tongue. XX, The fourth paire of sinews which goe into the coate of the pallat. Y, The fifth paire of sinews which are the nerves of hearing. a, the membrane of the eare, unto which that fifth nerve goeth. bc, two small branches of the fifth conjugation uniting themselves with the nerve P. d, the eight conjugation or a nerve of the fifth paire attaining unto the face. ee, the sixt paire of nerves. f, A branch from the nerve e, reaching to the muscles of the neck. g, Small branches derived unto the throttle or *larynx*. h, the byfurcation of the nerve into two branches. iii, An inner branch hanging to the rackbones, and strengthening the *intercostall* nerves, and is therfore called *Intercostalis*. kk, Surcles of the utter branch going to the heads of the muscles, to the breast-bone and to the collar-bones. lm, branches of the right nerve I, making the right Recurrent nerve.

mm, the infertion of the recurrent sinews into the muscles of the *larinx*. *op*, branches of the left nerve making the left recurrent sinew *p. qq*, branches from the sixth conjugation going to the coats of the lungs. *r*, small nerves of the heart and of the purse thereof called the *Pericardium*, as also some approaching to the coats of the lungs. *s*, nerves on either side sent to the stomach. *t*, the right stomacke nerve going to the left orifice of the stomach. *uu*, the left stomach nerve going to the right orifice of the stomach. *x*, a nerve from the branch *u*, passing into the hollownes of the liver. *y*, the nerve belonging to the right side of the keil. *z*, the nerve belonging to the collick gut. *a*, a nerve creeping to the gut called *duodenum* and the beginning of the *jejunum* or empty gut. *β*, a nerve implanted in the right side of the bottome of the stomach. *γ*, a nerve belonging to the liver and bladder of gall. *δ*, a nerve reaching unto the right kidney. *ε*, a branch reaching the *Mesenterium* and the guts. *ζ*, a branch sprinkled to the right part of the bladder. *η*, a branch going through the left part of the kel. *θ*, furcles derived to the collick gut and the kel. *κ*, small branches inserted into the spleen. *λλ*, a nerve approaching to the left side of the bottome of the stomach. *μ*, a branch belonging to the left side of the *Mesentery* and the guts. *ν*, a branch which attaineth to the left kidney. *ξ*, small nerves creeping through the left side of the bladder. *ο*, the seven paire of sinewes. *π*, a branch derived from the sixth conjugation to the muscles which arise from the proesse called *Styloides*. *ρ*, a branch of the seventh conjugation which goeth to the muscles of the tongue, of the bone *hyois*, and of the throtle or *larinx*. *ς*, A conjunction or coition of the 6. and 7. paire into one nerve.

What the
Apophyses Cli-
noides are.

Whether the
Retemirable
differ from the
Plexus choroi-
des,

These *Apophyses clinoides* are certaine productions of the *Os basilare* or wedge bone, (called the Saddle thereof,) between which, as I said, the pituitary glandule lies with part of the wonderfull net. There is a great controversie amongst Anatomists concerning this part; for *Vesalius* denies that it is in man, *Columbus* admits it, yet hee seemes to confound it with the *Plexus Choroides*. Truly I have observed it alwayes after the manner, as *Sylvius* alledges against *Vesalius*. It remaines, that we recite the perforations of the skull, because the knowledge of these much conduces to the understanding of the insertions of the veines, arteries and nerves.

CHAP. X.

Of the holes of the inner Basis of the Skull.

IN the first place are reckoned the holes of the bone *Ethmoides*; then those of the optick nerves; thirdly of the nerves moving the eyes. Fourthly of that portion, of the nerves, of the fourth conjugation which goe to the temporall muscles. Fifthly are reckoned, these holes scarce visible, situate under the pituitary glandule, by which the spittle is evacuated. Sixthly that hole which is in the wedge bone made for the entrance of the internall sleepey Arteries, composing the wonderfull Net, and then passing into the braine by a great slit. That perforation which we reckon in the seventh place is commonly double, made for the entrance of one of the branches of the internall Iugular veine. The eight hole is somewhat long, of an ovall figure, by which, part of the third conjugation and all the fourth conjugation passes forth. The ninth are the auditory passages. The tenth are very small holes, and give way to the veine and artery going to the auditory passage, above the *foramen cæcum*. In the eleaventh place are reckoned the perforations which yeild passage forth to the sixth paire of nerves, to part of the sleepey Arteries, and of the internall jugular. In the twelvth those which yeild a way out to the seventh conjugation; The great hole of the Nowle bone through which the spinall marrow passes is reckoned the thirteenth. The fourteenth is that, which most commonly is behinde that great hole, by which the Cervicall veines and arteries enter in.

CHAP. XI.

Of the perforations of the externall Balis of the Braine.

T Here is a hole on each side at the Eye-browes, by which passes a small nerve from the third coniugation comming out of the cavity of the Orbe of the eye, and going by the forehead bone to the eye-browes, that it may give motion to the two muscles of the upper eye-brow and forehead. Yet oftentimes the hole is but to bee seene on one side, oft times there is a cleft instead thereof, otherwhiles it is not perforated nor cleft at all. The second, is the perforation of the greater corner of the eye, by which a portion of the nerves of the third coniugation descends to the coate of the nose; in this hole the *Glandula Lachrymalis* is seated. The third is seated under the eye, that it may give way to the other portion of the nerves of the third coniugation going to the parts of the face, and the teeth of the upper jaw. The fourth is at the beginning of the pallate, amongst the cutting or shearing teeth, through which a veine, an artery and the coate of the pallate passes out. In the fifth order are reckoned the perforations of the pallate, by which the nerves descend from the fourth coniugation, to give, or cause the taste. In the sixth order are ranked the holes of the pallate serving for respiration, and the flegme falling from the braine by the nosethrils. And there is a cleft under the yoake bone ascending into the Orbe of the eye, by which there is a way, as wel for the nerves of the third coniugation to the Temporall muscles, as also for certaine veines and arteryes. But also there is noted another hole at the mammillary proceffe, which is not perforated in the iudgement of the sense. Besides there is thought to be another at the hinde roote of the same proceffe, by which a certaine small veine passes from the Iugular to the *Torcular*. But I have onely noted these three passages by the way, because there is so much variety in them, that nothing can be certainly said of them.

CHAP. XII.

Of the Spinall Marrow, or Pith of the Backe.

T He spinall Marrow is like a River running from the fountaine of the braine. This sends nerves for sense and motion to all the neighbouring parts under the head, spreading its branches as from the body of a tree. These branches, as we shall hereafter shew, are on each side thirty. This same spinall marrow is covered with the two membranes investing the braine, distinguished by no distance of place, as in the braine. But also it hath another membrane added to these, being very hard and dense, which keeps it from being broken and violated by the violent bending of the body forewards and about. The diseases of this marrow doe almost cause the like Symptomes, as the diseases of the braine; For they hurt the sense and motion of all the parts lying beneath them, as for example; If any of the vertebra's of the back bone, be moved out of their place, there followes a distortion or wresting aside of the Marrow; but then especially if it happen that one of the vertebra's be strained, so sharpe and bitter a compression urges the marrow by reason of the bony body of the vertebra, that it will either rend it, or certainly hinder the passage of the spirit by it. But by these same holes of the vertebra's the veines and arteryes goe to the spinall marrow for to give life and nourishment to it, as the nerves by them passe forth into all the lower parts of the body.

What the Spinall marrow is.

The coats of the spinall marrow.

The diseases from the hurting of the spinall marrow.

Figure 1. sheweth the forme of the spinall marrow properly so called, with its membranes, and the nerves proceeding from it.

Figure 2. The spinall marrow naked and bare, together with its nerves, as most part of Anatomists have described it.

The tenth figure of the spinall marrow.

- A**, The beginning of the spinall marrow where it falls out of the skull.
B, The thicknesse thereof in the spondels or rack-bones of the loynes.
C, The division thereof into strings, or hairy threds.
D, the seven nerves of the necke.
 From **D** to **E** or from 7, to 19, shew the nerves of the backe.
 From **E** to **F**, the nerves of the loynes.
 From **F** to **G**, the nerves of the *os sacrum* or holy bone.
H, the end of the marrow.
I K L, do shew how the nerves doe issue from the marrow in strings.
M M, the knots of the sinewes made of the conjunction of those strings.
N O, the membranes that invest the marrow.

Figure 2.

- A**, The beginning of the spinall marrow in the skull.
3, 4, 5, 6, 7, These Characters shew (according to *Vesalius* opinion) how the conjugations of the nerves of the braine doe take their originall from the marrow remaining yet within the Skull.
B, The egress of the spinall marrow out of the skull.
C, The cords or strings whereinto it is divided.

D 7, The marrow of the necke and seven paire of sinewes. **E 19**, twelve paires or conjugations of nerves proceeding from the marrow of the Chest. **F 24**, The marrow of the loynes and 5. paire of sinewes. **G 30**. the marrow of the holy-bone and 6, paire of sinewes. **H**, the extremity or end of the spinall marrow.

The End of the Fifth Booke.

THE

THE SIXTH BOOKE TREATING OF

the Muscles and Bones, and the other
Extreme parts of the Body.

The Preface.

IF peradventure some may wonder, that I have ended my fifth booke of Anatomie, before I have fully described all the parts of the head, the which seemed as it were onely appointed for that purpose. Therefore I must yeeld a reason of this my intention. I have a desire in one Treatise and as it were at one breath, to prosecute the Anatomy of the Muscles. Wherefore because the parts of the head not yet described, principally consist of the Muscles, therefore I desired to comprehend them together with this same description of the extreme parts of the body; beginning at the upper part of the face, to wit, the eyes: but having first described the bones of the face, without the knowledge of which it is impossible to shew the originall and insertion of the Muscles. We have formerly noted that by the face is meant whatsoever lyes from the Eye-browes even to the Chin. In which there is such admirable industry of nature, that of the infinite multitude of men you cannot finde two so like, but that they may be distinguished by some unlikenesse in their faces; also it hath adorned this part with such exquisite beauty, that many have dyed by longing to enjoy the beauty desired by them. This same face albeit it little exceeds halfe a foote, yet it indicates and plainly intimates by the suddaine changes thereof, what affections and passions of hope, feare, sorrow and delight possesse our minds; and what state our bodies are in, sound, sicke or neither. Wherefore seeing the face is of so much moment, let us returne to the Anatomicall description thereof, which that wee may easily and plainly performe wee will begin with the bones thereof, whereby, as we formerly sayd, the originall and insertion of the Muscles may be more certaine and manifest to vs.

The description of the bones being unknowne it must necessarily follow that the originall and insertion of the muscles must be so also

The endowments of the face.

The creature's nature is the bewrayer of the will.

CHAP.

CHAP. I.

Of the bones of the Face.

Bones in each
orbe of the
Eye.

What the
Zygoma is and
what use it
hath.

The *Ægylops*.

The two
bones of the
nose.
The two in-
ner bones of
the palate.

He bones of the face are 16, or 17, in number. And first, there be reckoned 6 about the Orbs of the eyes, that is 3 to each orbe, of which one is the bigger, another lesser, and the third between both; each of these touch the forehead bone in their upper part. Besides, the greater is joyned with a suture to the proceffe of the stony bone, and so makes the *Zygoma*, that is, the *Os Iugale* or yoake bone, framed by nature for preservation of the temporall muscle. The lesser is seated at the greater corner of the eye, in which there is a hole perforated to the nose, and in this is the glandule in which the *Ægylops* doth breed. The middle is in the bottome, or inner part of the orbe, very slender & as it were of a membranous thinnesse: then follow the two bones of the nose which are joyned to the forehead bone by a suture, but on the foreside between them selves by harmony. But on the backe or hinde part with two other bones, on each side one, which descending from the bone of the forehead (to which also they are joyned by a suture) receive all the teeth. These two in *Galens* opinion are seldome found separated. But these are the thickest of all the bones of the face hitherto mentioned, knit by a suture with the greatest bone of the Orbe, on the backe part with the wedge-bone, on the inner side with the two little inner bones of the pallate, which on the inside make the extremity thereof, whereby it comes to passe, that we may call these bones the hinder, or inner bones of the pallate. They reckon one of these bones the eleventh and the other the twelfth bone of the head; these two little bones on their sides next to the winged productions of the wedge-bone, receive on each side one of the nerves of the fourth conjugation, which in the former booke, we said were spent upon the membrane of the pallate.

The two
bones of the
jaw.

Two pro-
ductions on
each side
of the lower
law.

And in *Galens* opinion there be other two in the lower law, joined at the middle of the chin; although some thinke it but one bone, because by the judgement of sense there appeares no division or separation therein. But you may see in children how true this their supposition is, for in men of perfect growth it appeares but one bone; these two are reckoned for the thirteenth and fourteenth bones. Now these two bones making the lower law, have in their back part on each side two productions, as they lye to the upper law, the one of which represents the point of a sword, and is called the *Corone*; the other is obtuse and round, which is inserted into the cavity seated at the root of the proceffe of the stony bone, nere to the passage of the eare.

The Luxation
of the lower
law.

This may be strained to the forepart by violent gaping, by retraction of the muscles arising from the wing-like proceffes, and ending at the lower angles of the broader part of the same law.

The lower
law filled
with a mar-
rowy humor.

This law is hollow as also the upper, especially in the back-part, being filled with a white and glutinous humor, conducing to the growth of the teeth. This humor hath its matter from the blood brought thither by the vessels, veines, Arteryes and nerves from the third coniugation entring in here by a passage large enough. Whereby it comes to passe, that this part is not only nourished and lives, but also the teeth receive sence by the benefit of the nerves entring thither with the veine and artery, by small holes to be seene at the lower roots of the teeth; and thence it is that a beating paine may be perceived in the tooth-ach, because the defluxion may be by the arteryes; or rather because the humor flowing to the roots of the teeth may presse the artery in that place; beside also you may see some apparance of a nervous substance in the root of a tooth newly pluckt out.

How the teeth
feele.

Why the teeth
have a beating
paine.

The nerves of
the Lower
law must be
observed.

But also you must consider, that this law from its inner capacity produces at the sides of the chin two nerves of a sufficient magnitude, over against the lower dog-teeth and the first of the smaller grinding teeth, as I have noted in the description of the nerves of the third coniugation. I have thought good to put thee in minde of these, that when thou shalt have occasion to make incision in these places, thou maiest warily and discreetly handle the matter, that these parts receive no harme.

There

There remaines another bone seated above the pallate, from which the gristlely partition of the nose arises, being omitted of all the Anatomists, for as much as I know. Now therefore that you may the better remember the number of the bones of the face, I will here make a repetition of them.

The bone of the nose above the palate, or the partition of the nose.

There are sixe of the orbs of the eyes, at each three. The seventh and eight wee may call the Nasall, or nose bones. The ninth and tenth the Jaw-bones. The eleventh and twelfth are called the inner bones of the pallate. The thirteenth and fourteenth the bones of the lower Jaw. The partition of the nose may be reckoned the fifteenth.

Now it remaines having spoken of these bones, that wee treat of the teeth, the Eye-browes, the skinne, the fleshy pannicle, the Muscles, and lastly the other parts of the face.

CHAP. II.

Of the Teeth.

The Teeth are of the number of the bones, and those which have the most have thirty two, that is, sixteene above, and so many below; of which in the forepart of the mouth there are foure above and as many beneath, which are called *Incisorij* cutting or shearing teeth, to cut in sunder the meat, and they have but one root. To these are ioyned two in each Jaw, that is, on each side of the other one, which are called *Canini dentes*; Dogges-teeth, because they are sharp and strong like dogges teeth; these also have but one roote; but that is farre longer than the other have.

The teeth are bones.

The shearing teeth.

The Dogteeth

Then follow the *Molares* or Grinders, on each side five, that is, tenne above and as many below, that they may grinde, chew and breake the meat, that so it may be the sooner concocted in the stomack; for so they vulgarly thinke, that meat well chewed is halfe concocted; those grinders which are fastened in the upper jaw, have most commonly three roots, and oft times foure. But these which are fastened in the lower, have only two roots, and sometimes three, because this lower jaw is harder than the upper so that it cannot be so easily hollowed, or else because these teeth being fixed and firmly seated, needed not so many staves as the upper, which as it were hang out of their seats. The shearing teeth cut the meat because they are broad and sharp; the Dog-teeth break it because they are sharp pointed and firme; but the grinders being hard, broad and sharp, chew and grind it asunder. But if the grinders had beene smooth, they could not fitly have performed their duty, for all things are chewed and broken asunder more easily by that which is rough and unequall.

The Grinding teeth.

Why the upper grinding teeth have more rootes.

The use of the teeth.

Wherefore they sharpen their Millstones when they are smoother than they should be, by picking them with a sharp Iron. The teeth are fastened in the jawes by *Gomphosis*, that is, as a stake or naile, so are they fixed into the holes of their jawes; for they adhere so firmly thereto in some, that when they are pluckt out, part thereof followes together with the tooth; which I have often observed to have beene also with great effusion of blood. This adhesion of the teeth fastened in their jawes is besides strengthened with a ligament, which applyes it selfe to their roots together with the nerve and vessels. The teeth differ from other bones, because they have action whilest they chew the meat; because being lost they may be regenerated, and for that they grow as long as the party lives, for otherwise by the continuall use of chewing they would be worne and wasted away by one another. You may perceive this by any that have lost one of their teeth, for that which is oppositeto it becomes longer than the rest, because it is not worne by its opposite. Besides also they are more hard and solide than the rest of the bones, and indued with a quick sense by reason of the nerves of the third conjugation which insert themselves into their roots; for if you rub, or grind a tooth newly pluckt out, you may see the remaines of the nerve; they have such quick sense, that with the tongue they might judge of tastes. But how feeble the teeth, seeing they may be filed without paine? *Fallopianus* answeres, that the teeth feeble not in their upper or exterior part, but only by a membrane which they have within. And

The teeth are fastened in the Jawes by Gomphosis.

The fastening of the teeth into the jawes is to be observed.

Wherein the teeth differ from the other bones.

For what use the teeth have sense.

the

The foreteeth
helpe for the
articulation of
the voyce;

the teeth have another use, especially the fore-teeth, which is, they serve for distinct and articulate pronuntiation; for those that want them fault in speaking, as also such as have them too short, or too long, or ill ranked. Besides, children speak not distinctly before they have their foreteeth. And you must note that the infant as yet shut up in its mothers womb hath solide and bony teeth; which you may perceive by dissecting it presently after it is borne.

But even as there are two large cavities, in the forehead bone at the eye-browes, filled with a viscous humor, serving for the smelling; and in like manner, the aire shut up in the mamillary processes is for hearing; so in the jawes there be two cavities furnished with a viscid humor for the nourishment of the teeth.

CHAP. III.

Of the Broade Muscle.

Now we should prosecute the containing parts of the face, to wit the skin, the fleshy pannicle and fat; but because they have beene spoken of sufficiently before, I will onely describe the fleshy pannicle, before I come to the dissection of the eye, that wee may the more easily understand, all the motions performed by it, whether in the face or forehead.

First that you may more easily see it, you must curiously separate the skin in some part of the face. For unlesse you take good heed, you will pluck away the fleshy pannicle together with the skinne, as also this broad muscle to which it immediatly adheres, and in some places so closely and firmly, as in the lips, eye-lids and the whole forehead, that it cannot be separated from it. Nature hath given motion, or a moving force to this broad muscle, that whilst it extends, or contracts it selfe, it might serve to shut and open the eye. It will be convenient to separate the muscle thus freed from the skin, beginning from the forepart of the clavicles even to the chin, ascending in a right line, and then turning backe as far as you can; for thus you shall shew how it mixes it selfe with the skinne and the muscles of the lips.

There are no
particular
muscles ap-
pointed to
open and shut
the eye, for
that is the
worke of the
broad muscle
onely.
Divers reasons
to that pur-
pose.

When thou shalt come to the Eyes, thou shalt teach how the eye is shut and opened by this one muscle, because it is composed of the three sorts of fibers; although by the opinion of all who have hitherto written of Anatomy, those actions are said to be performed by the power of two muscles appointed for that purpose; one of which is at the greater corner on the upper part, the other resembling a semicircle at the lesser corner, from whence extending it selfe to the middle of the gristle *Tarsus*, it meets with the former ending there, but they are in part extended over all the eyelid, whereby it commeth to passe that it also in some sort becometh moveable. But although in publike dissections these two muscles are commonly wont to be solemnly shewed, after the manner I have related; yet I thinke, that those which shew them know no more of them, than I doe. I have grounded my opinion from this, that there appeares no other musculous flesh in these places, to those which separate the fleshy pannicle, or broad muscle, than that which is of the panicle it selfe, whether you draw your incision knife from the forehead downwards, or from the cheek upwards.

Why you
must take
heede of ma-
king a trans-
verse incision
upon the eye-
browes.

The action of
a muscle.

Besides when there is occasion to make incision on the eye-browes, we are forbidden to doe it transverse, least this broad muscle falling upon the eye, make the upper Eye-lid unmoveable; but if such a cut be received accidentally, we are commanded presently to stitch it up; which is a great argument that the motion of the upper eye-lid is not performed by its proper muscles, but wholly depends and is performed by the broad muscle. Now if these same proper muscles which we have described should be in the upper eye-lid, it should be meet, (because when one of the muscles is in action, the other which is its opposite or Antagonist, rests or keeps holiday,) that when that which is said to open the eye is imployed, the opposite thereof resting, the upper eye-lid should be drawne towards its originall, as we see it happens in convulsions: because the operation of a muscle is the collection of the part which it moves towards its originall.

Therefore

Therefore seeing such a motion or collection appears not any where in the eye-lid, I thinke it therefore manifest that all the motion of this upper eye-lid depends upon this broad muscle, and that it alone is the author of the motion thereof.

The originall of this broad muscle is from the upper part of the *Sternum*, the clavicles, the shoulder blades, and all the spines of the *vertebra's* of the neck: but it is inserted into all these parts of the head which want haire, and the whole face, having divers fibers from so various an originall. by benifit of which it performes such manifold motions in the face (for it so spreads it selfe over the face, that it covers it like a vizard) by reason of the variety of the originall and the production of the divers fibers of this muscle. But I have not in the description of this muscle prosecuted those nine conditions, which in the first booke of my anatomy I required in every part, because I may seeme to have sufficiently declared them in the description of the muscles of the *Epigastrium*. Wherefore hence forward you must expect nothing from me in the description of muscles besides their originall, insertion, action, composition, and the designation of their vessels.

The originall of the broad muscle.
The insertion and reason why we express so many motions with the face.

CHAP. IIII.

Of the Eye-lids and Eye-browes.

BEcause wee have fallne into mention of the Eye-lids and Eye-browes, and because the order of dissection also requires it, we must tell you what they are, of what they consist, and how and for what use they were framed by nature. Therefore the Eye-browes are nothing els, than a ranck of haire set in a semi-circular forme upon the upper part of the orbe of the Eye, from the greater to the lesser corner thereof, to serve for an ornament of the body and a defence of the eyes against the acrimony of the sweat falling from the forehead.

What the eye-browes are.

Their use

But the Eye-lids on each side two, one above and another below, are nothing els than as it were certaine shuttings appointed and made to close and open the eyes when need requires, and to containe them in their orbes. Their composition is of a musculous skin, a gristle and haire set like a pale at the sides of them to preserve the eyes when they are open, chiefly against the injuries of small bodyes, as motes, dust & such like. These haire are alwaies of equall and like bignesse, implanted at the edges of the gristly part, that they might alwaies stand straight and stiffe out. They are not thick, for so they should darken the eye. The gristle in which they are fastened is encompassed with the *pericranium* stretched so far before it produce the *Coniunctiva*. It was placed there, that when any part thereof should be drawne upwards or downewards by the force of the broad muscle or of the two proper muscles, it might follow entirely and wholly by reason of its hardnes. They call this same gristle, especially the upper, *Tarsus*. The upper and lower eye-lid differ in nothing, but that the upper hath a more manifest motion, and the lower a more obscure; for otherwise nature should have in vaine encompassed it with a musculous substance.

What the eye-lids are.

Their composition and use.

What the Tarsus is.

CHAP. V.

Of the Eyes.

THE Eyes are the instruments of the faculty of seeing, brought thither by the visive spirit of the opticke nerves, as in an aqua-ducte. They are of a soft substance, of a large quantity, being bigger or lesser according to the bignesse of the body. They are seated in the head, that they might overlooke the rest of the body, to perceive and shun such things as might endanger, or en-damage the body; for the action of the eyes is most quick, as that which is performed in a moment, which is granted to none of the other senses. Wherefore this is the most excellent sense of them all. For by this wee behold the fabricke and beauty of the heavens

What the eyes are.

Their site,

The quicknes, and excellency of their action

heavens and earth, distinguish the infinite varieties of colours, we perceive and know the magnitude, figure, number, proportion, site, motion and rest of all bodies. The eyes have a pyramidall figure whose basis is without, but the Cone or point within at the opticke nerves. Nature would have them contained in a hollow circle, that so by the profundity and solidity of the place they might be free from the incursions of bruising and hurtfull things.

Figure. They are composed of six muscles, five coats, three humors, and a most bright spirit, (of which there is a perpetuall afflux from the braine) two nerves, a double veine, and one artery, besides much fat, and lastly a Glandule seated at the greater angle thereof, uppon that large hole which on both sides goes to the nose, and that, lest that the humours falling from the braine should flow by the nose into the eyes, as we see it fares with those whose eyes perpetually weep, or water, by reason of the eating away of this glandule, whence that affect is called, the *Fistula lachrymalis*, or weeping Fistula.

Composition. But there is much fat put between the muscles of the eye, partly that the motion of the eyes might be more quick, in that slipperines of the fat, as also that the temper and complexion of the eyes, and chiefly of their nervous parts, might be more constant and lasting, which otherwise by their continuall and perpetuall motion would be subject to excessive drynesse. For nature, for the same reason hath placed Glandules flowing with a certaine moisture, neere those parts which have perpetuall agitation.

Glandula Lachrymalis.

Fistula Lachrymalis.

Why fat is placed about the eyes.

CHAP. VI.

Of the Muscles, Coats and humors of the Eye.

The number, site and action of the muscles.

Here are sixe muscles in the eye, of which foure performe the foure direct motions of the eye: they arise from the bottome of the orbe, and end in the midst of the eye encompassing the opticke nerve. When they are all moved with one endeavour, they draw the eye inwards. But if the upper only use its action, it drawes the eye upwards; if the lower, downewards; if the right, to the right side; if the left, to the left side.

The two other muscles turne the eye about, the first of which being the longer and slenderer, arises almost from the same place, from which, that muscle arises which drawes the eye to the right side to the greater corner. But when it comes to the utmost part of the inner angle, where the *Glandula lachrymalis* is seated, it ends in a slender Tendon, there peircing through the middle membrane which is there, as through a ring; from whence it presently going backe is spent in a right angle towards the upper part of the eye, betwixt the insertions of those 2 muscles, of the which one draws the eye upwards, the other directly to the outward corner, as it is observed by *Fallopins* or rather, which I remember I have alwaies observed, they turne between the muscles which move the eye upwards, and to the inner corner.

This fifth muscle when it is drawne in towards its beginning, so drawes the eye with its circular tendon, that it carries it to the greater corner.

The sixt muscle is contrary to that, for it hath its originall from the lower part of the orbe at a small hole, by which a nerve of the third conjugation passes forth; and being that it is most slender, whilest it ascends transversely to the outward corner, it involves the eye so also, that it is inserted in it by a small Tendon, so that the Tendons of them both are oftentimes taken but for one. That thou maiest truely and accurately observe this anatomick description of the eye; the eye must not be pluckt out of its orbe, but rather the orbe it selfe must be broken and separated.

The 5 coats of the eye.

I
Conjunctiva, or Adnata.

For thus thou shalt certainlie and plainelie see the forementioned originall of the muscles. For the five coats, the first which is first met with in dissection, comes from the pericranium, and is extended over all the white of the eye, even to the *Iris* or Rainbow. The duty of it is to strengthen, bind and containe the eye in its orbe, wherefore it had the name *Conjunctiva*, others call it *Adnata*, or *Epipephycos*.

The

The second is called the *Cornea*, because it resembles a horne in colour and consistence; this coat differs and varies from it selfe, for in the forepart, as far as the *Iris* goes, it is clear and perspicuous, but thick & obscure in the hinde part, by reason of the diverse polishing. On the fore-part it is dense that it may preserve and containe the Christalline and waterish humor, but withall transparent so to give the object a freer passage to the Chrystalline. It hath its originall from the *Crassameninx*, proceeding forth from the inner holes of the orbe of the eye, for it compasses the eye on every side.

2.
(*cornea*), or the
Horny coate.

The third is called the *Vvesa* or Grapy coat, because in the exterior part it represents the colour of a black grape; it arises from the *Pia mater*, and encompasses all the eye, except the *pupilla* or apple of the eye, for here being perforated, it adheres to the horny coate by the veines and arteries which it communicates to it for life and nourishment. But when it arrives at the *Iris*, then forsaking the *Cornea*, it descends deep into the eye, and in some sort is turned about the Christalline humour, to which also it most firmly adheres, so bounding the waterish humor, and also prohibiting that the Albugineous humor doe not overwhelm the Christalline. This grapy coate is as it were dyed on the inside with divers colours, as black, browne, blew, or green like a raine-bow, and that for these ensuing benifits.

3
Vvesa, or the
grapy coate.

Why the grapy
coate re-
sembles divers
colours.

The first is, if that it had beene tintured with one colour, all objects would have appeared of the same colour, as it comes to passe when we looke through green or red glasse. But it must be coloured, that so it may collect the spirits dissipated by the Sunne and seeing.

Thirdly it was convenient it should be painted with infinite variety of colours for the preservation of the sight. For as the extreame colours corrupt and weaken the sight, so the middle refresh and preserve it, more or lesse as they are neerer, or further remote from the extremes. It was fit it should be soft, that so it might not hurt the Christalline humor uppon whose circumference it ends; and perforated in the part objected to it, least by its obscurity it should hinder the passage of the objects to the Christalline, but rather that it might collect by its blacknes as a contrary, the great and as it were diffused variety of colours, no otherwise than wee see the heat is strengthened, by the opposition of cold; some call this coat *Choroides*, because it is woven with many veines and arteries, like the coat *Chorion* which involves the infant in the wombe.

Now followes the fourth coate called *Ampiblistroides* or *Retiformis*, the Net-like coate, because proceeding from the opticke nerve dilated into a coate, it is woven like a net with veines and arteries which it receives from the grapy coate, both for the life and nourishment both of its selfe, as also of the glassie humor which it encompasses on the back part. The principall commodity of this coate is, to perceive when the Christalline humor shall be changed by objects, & to leade the visive spirit instructed or furnished with the faculty of seeing, by the mediation of the glassie humor, even to the Christalline being the principall instrument of seeing. It is softer than any other coate, least the touch of it should offend that humor. Wherein thou wilt admire the singular order of nature, which as in other things it passes not from one extreme to another unlesse by a *Medium*, so here it hath not fitted the hard horny coate to the soft humors, but by interposition of divers *media* of a middle consistence. For thus after the harder coats *Adnata* and *Cornea* it hath placed the Grapy coate, by so much softer then these two, as the Net-like coat is softer then it, that thus it might passe from extreme to extreme as it were by these degrees of hardnes and softnes.

4.
Ampiblistroi-
des or *Retiformis*, Net-like
coate.

An anatomis
call *Axioma*.

The fifth and last coate is called *Arachnoides*, because it is of the consistence of a spidersweb. And wee may well resemble this coate, to that skin of an union which exceeds the other in clearnesse, whitenesse and thinnesse. This *Araneosa* or Cobweb-like coate encompasses the Christalline humor on the fore side, peradventure that so it might defend it, as the chiefe instrument of seeing, if the other humors should at any time bee hurt. It hath its originall from the excrementitious humidity of the Christalline humor, hardened into that coate by the coldnes of the adjacent parts; absolutely like the thin skin which encompasses the white of an Egge.

5
Arachnoides,
five *Araneosa*,
the Cobweb-
coate.

The 3 humors
of the Eye.

I
Aqueus, or
matery.

The first humor of the eye is called the *Aqueus* or waterish, from the similitude of water; it is seated betwene the transparent part of the Horny coate, the portion

of the Chrystalline humor lying towards the apple of the eye, and that reflection of the Grapy coate which comes from the *Iris* to the circumference of the Chrystalline humor, that filling the empty space it may distend the *Cornea*, and so hinder the falling thereof upon the Chrystalline which would spoyle the sight; as also that by its moisture it might hinder the drying of the Chrystalline humor. Peradventure it is made of the whayish humor sweating out of the vessells of the coats, having their orifices for the most part in that place, where this waterish humor resides. The second humor and middle most in scituation is called the Chrystalline because it imitats Crystall in the brightnesse and colour; if so be that we may attribute any colour to it. For indeed it was fit that none of the three humors should be tintured with any colour, as those which should be the instruments of sight, lest they might beguile us in seeing as Red and greene spectacles doe; for that is true which wee have read written by the Philosopher; That the Subject or matter appointed for the reception of any forme should want all impression thereof. Hence Nature hath created a formelesse matter, the humors of the eyes without colours, waxe without any figure, the minde without any particular knowledge of any thing, that so they might be able to receive all manner of formes. The figure of the Crystalline humor is round, yet somewhat flatted on the foreside, but yet more flatted behinde that so the objects might be the better retained in that, as it were, plane figure, and that they might not fly backe as from a Globe, or round body, in which they could make but short stay; lest it might be easily moved from its place, by the force of any thing falling or hitting against it, because that body which is exactly round touches not a plane body but onely in a point or pricke. Halfe this humor swims in the Glassy humor, that so it may be nourished from it by transposition of matter; or rather (seeing it is encompassed on every side with the fist coate, that the matter cannot easily be sent from the one into the other) by the benefit of the vessells produced even unto it as well by the Net-like coate, as by the Grapye; but it is filled with a bright spirit on the forepart, which lyes next to the waterish humor, and the space of the Apple of the eye.

Of which thing this is an argument, that as long as a man remaines alive, wee see the eye every way full, and swollne, but lanke and wrinkled when he is dead; besides also one of the eyes being shut, the *Pupilla* of the other is dilated by the spirit compelled to fly thither. And also for the same cause the horny coate is wrinkled in very old men, and the *Pupilla* is straitned by the wrinkles subsiding into themselves, which is the cause that they see litle, or not at all; for by age and successe of time the humor is consumed by litle and litle, the implanted spirit vanishes away, and smaller quantitie of spirits flow from the braine, as from a fountaine which is also exhausted. The Horny coate at his originall, that is, in the parts next the *Iris*, seemeth to be very nigh the Crystalline Humor, because all the coates in that place mutually cohere as touching one another, but as it runnes further out to the *Pupilla*, so it is further distant from the Crystalline. Which you may easily perceive by Anatomically dissection, and the operation of touching or taking away a Catarrhact: for whereas a Catarrhact is seated betweene the horny coate, and Crystalline humor, the needle thrust in, is carried about upwards, downewards, and on every side through a large and free space, neither touching the horny coate nor Crystalline humor, by reason these bodies are severed by a good distance filled with spirit and a thin humor. The use of it is, that it may be like a looking-glasse to the facultie of seeing carried thither with the visive spirit.

The third and last humor is the *Vitrens* the glassie, or rather Albugineous humor, called so, because it is like molten glasse, or the white of an Egge. It is seated in the hind part of the Crystalline humor that so it may in some sort breake the violence of the spirit flowing from the braine into the Crystalline humour, no otherwise than the watry humor is placed on the foreside of the Crystalline to hinder the violence of the light and colours entering that way. This glassie humor is nourished by the net-like coate.

We have formerly spoken sufficiently of the nerves of the eye: Wherefore it remaines that we speake of the veins. Some of these are internall, carried thither with the

flamations
of the eyes.

the coats of the vessels of the braine; other some externall stretched over the externall parts of the eye, as the Muscles, and coat *Adnata*, and by these veines inflammations and rednesse often happen in the externall parts of the eye: for which the *Vena pupis* must be opened, and cupping glasses and hernes must be applied to the nape of the necke and shoulders; as in the internall inflammations of the eye the cephalike veine must be opened to avert and evacuate the morbidicke humor.

CHAP. VII.

Of the Nose.

 The Nose is called in Greeke *Ris*, because the excrements of the Braine flow forth by this passage, thou maiest understand it hath a divers substance by composition. The quantity, figure and site are sufficiently knowne to all. But it is composed of the skinn and muscles, bones, gristles, a membrane or coate nerve, veines and arteries. The skin and bones both contained and containing, have formerly beene explained, as also the nerves, veines and arteries. The gristles of the Nose are sixe in number; the first is double separating both the nose-thrills in the top of the nose extended even to the bone *Ethmoides*. The second lyes under the former. The third and fourth are continued to the two outward bones of the nose. The fifth & sixth being very slender and descending on both sides of the nose, make the wings or moveable parts thereof. Therefore the use of these gristles is, that the nose moveable about the end thereof, should be lesse obnoxious to externall injuries, as fractures & bruses, and besides more fit for drawing the aire in & expelling it forth in breathing. For nature for this purpose hath bestowed foure muscles upon the nose, on each side two, one within, and another without.

The Gristles
of the nose.

The muscles
thereof.

The Externall taketh its originall from the cheek, and descending obliquely from thence and after some sort annexed to that which opens the upper lip, is terminated into the wing of the nose, which it dilates.

The internall going on the inner side from the jaw bone, ends at the beginning of the gristles that make the wings, that so it may contract them. The coate which inwardly invests the nose-thrills and their passages is produced by the five like bones from the *Cassa meninx*, as the inner coate of the Palate, throtle, weazon, Gullet and inner ventricle, that it is no mervaille, if the affects of such parts be quickly communicated with the braine. This same coate on each side receives a portion of a nerve from the

the third conjugation, through the hole which descends to the nose by the great corner of the eye.

The nose in all the parts thereof is of a cold and dry temper. The Action and profit thereof is to carry the aire and oft times smells to the mammillary processes, and from thence to the foure ventricles of the braine, for the reasons formerly shewed. But because the mammillary processes being the passages of the aire and smells are double, & for that one of these may be obstructed without the other, therefore nature hath also distinguished the passage of the nose with a gristly partitiō put between, that when the one is obstructed, they aire by the other may enter into the braine for the generation and preservation of the animall spirit. The two holes of the nose first ascend upwards; and then downewards into the mouth, by a crooked passage, lest the cold aire, or dust should be carryed into the lungs. But the nose was parted into two passages as we see, not onely for the fore mentioned cause, but also for helping the respiration and vindicating the smell from externall injuries, and lastly for the ornament of the face.

The temper,
action and use.

Why the nose
was parted in
two.

CHAP. VIII.

Of the muscles of the face.

II. 21

Now we must describe the muscles of the face pertaining as well to the lips as to the lower jaw. These are 18. in number, on each side nine, that is, foure of the lips, two of the upper, and as many of the lower. But there belong five to the lower jaw. The first of the upper lip being the longer, and narrower, arising from the yoke-bone descends by the corner of the mouth to the lower lip, that so it may bring it to the upper lip, and by that meanes shut the mouth. The other being shorter and broader, passing forth of the hollownes of the cheek, or upper jaw (by which a portion of the nerves of the third conjugation descends to these two muscles, and other parts of the face) ends in the upper part of the same upper lip, which it composes together with the fleshy pannicle and skin, and it opens it by turning up the exteriour fibers towards the nose, and shuts it by drawing the internall inwards towards the teeth.

There nume
ber.

The first of the lower lip being the longer and slenderer, entring out of that region which is between the externall perforation of the upper jaw (through which on the inner part of the same, a nerve passeth forth to the same muscles) and the muscle *Masseter*, (of which hereafter) then ascending upwards by the corner of the mouth, it ends in the upper lip, that so it may draw it to the lower.

The other broader and shorter begins at the lower part of the Chin and the hollownes thereof, and ends at the lower lip which it makes, opening it within and without by its internall and externall fibers, as we also said of its opposite. And that I may speake in a word, Nature hath framed three sorts of Muscles for the motion of the mouth, of which some open the mouth, others shut it, and othersome wrest it and draw it awry, but you must note that when the muscles of one kind joyntly performe their functions (as the 2 upper which we described in the first place, on each side one which draw the lower lip to the upper, and the muscles opposite to them) they make a right or straight motion; but when either of them moves severally, it moves obliquely, as when we draw our mouth aside. But these muscles are so fastened and fixed to the skin, that they cannot be seperated; so that it is no great matter whether you call it a musculous skin, or a skinny muscle (Which also takes place in the palmes of the hands and soles of the feet) but these muscles move the lips, the upper jaw being not moved at all.

CHAP. IX.

Of the Muscles of the lower Jaw.

Their number

The Temporal Muscle.

Why the wounds of the temporal Muscle are deadly.

WE have said these muscles are five in number, that is, foure vvhich shut it, and one which opens it, and these are alike on both sides. The first and greater of these foure muscles vvhich shut the Iawv is called *Crotophita* or Temporal muscle, it arises from the sides of the forehead and *Bregma* bones, and adhering to the same and the stony bone, it descends under the yoke bone, from vvhence it inserts it selfe to the proceffe of the lower Iawv vvhich the Greeks call *Corone*, that it may draw it directly to the upper, so to shut the mouth.

But you must note, that this muscle is tendinous even to his belly, and that it fills and makes both the temples. It is more subject to deadly wounds than the rest by reason of the multitude of nerves dispersed over the substance thereof, which because they are nere their originall, that is, the brain, they are in danger of suddaine death by a convulsion which usually follows the affects of this muscle; but also in like manner it causes a fever, the Phrenzy and Coma.

I. The Masseter, or Grinding Muscle.

K. The upper gristle of the nose.

M. A muscle forming the cheekes.

N. The muscle of the lower lip.

O. A part of the Fifth muscle of the lower Jaw called Digastricus, that is, double bellied.

Q. R. The first muscle of the bone Hyoides growing unto the rough Artery.

S. The second muscle of the bone Hyoides under the Chin.

T. The third muscle of the bone Hyoides stretched to the Jaw.

T.K. the seventh muscle of the head and his insertion at T.

V.V. The two venters of the fourth muscle of the bone Hyoides.

φ. The place where the vessels passe which go to the head, and the nerves which are sent to the Arme.

The Masseter, or grinding muscle.

Therefore that it should be lesse subject or obvious to externall injuries, Nature hath, as it were, made it a retiring place in the bone, and fortified it with a wall of bone raised somewhat higher about it. The other Muscle almost equall to the former in bignes, being called the *Masseter*, or grinding muscle, makes the Cheeke, it descends from the lowest part of the greatest bone of the orbe (which bends it selfe as it were back, that it may make part of the yoke bone) and inserts it selfe into the lower Jaw, from the corner thereof to the end of the root of the proceffe *Corone*, that so it may draw this Jaw forward and backward, and move it like a hand-mill.

Wherefore nature hath composed it of two sorts of fibers, of the which some from the neeke (the cheek in that place under the eyes standing somewhat out like an aple arising from the concurrence of the greater bones of the orbe and upper jaw) descend obliquely to the corner and hinder part of the lower jaw, that it may move it forwards. Other some arise from the lower part of the same yoke-bone, and descending obliquely intersect the former fibers after the similitude of the letter X, and insert themselves

themselves into the same lower jaw at the roots of the *proccesse Corone*, that so they may draw it back. Truly by reason of these contrary motions it is likely this muscle was called the *Maffeter* or grinder.

The third, which is the round Muscle, arises from all the Gums of the upper jaw, and is inserted into all the gummies of the lower, investing the sides of all the mouth with the coate, with which it is covered on the inside, being otherwise covered on the outside with more fat than any other muscle. The action thereof is, not onely to draw the lower jaw to the upper, but also as with a Shovell to bring the meat dispersed over all the mouth under the teeth, no otherwise then the tongue drawes it in.

The round muscle.

The fourth being shorter and lesse than the rest arising from all the hollownes of the winged proccesse of the Wedge-bone, is inserted within into the broadest part of the lower jaw, that so in like manner it may draw the same to the upper. This is the muscle through whole occasion, we said this lower jaw is sometimes dislocated.

The lesser muscle of the lower jaw.

The fifth and last muscle of the lower jaw from the proccesse *styloides* of the stony bone, ascends to the forepart of the Chin, nere to the connexion of the two bones of this jaw, to draw this jaw downewards from the upper in opening the mouth. This muscle is slender and Tendinous in the midst, that so it might be the stronger, but it is fleshy at the ends. All these Muscles were made by the singular providence of nature and ingrafted into this part for the performance of many uses and actions, as biting asunder, chawing, grinding and severing the meat into small particles, which the tongue by a various and harmelesse motion puts under the teeth. Thus much I thought good to say of the parts of the face, as well containing as contained.

The fifth and last muscle.

The use of these mentioned muscles.

CHAP. X.

Of the Eares and Parotides or kernels of the Eares.

He Eares are the Organs of the Sense of hearing. They are composed of the skin, a little flesh, a gristle, veines, arteries and nerves. They may be bended or folded in without harme, because being gristlely, they easily yeild and give way; but they would not doe so, if they should be bony, but would rather break. That lap at which they hang pendants and lewels, is by the ancients called *Fibra*; but the upper part *pinna*. They have beene framed by the providence of nature into twining passages like a Snailles shell, which as they come neerer to the *foramen caecum*, or blind hole, are the more straitened, that so they might the better gather the aire into them, & conceive the differences of sounds and voices, and by little and little leade them to the membrane.

The nature and composition of the eares.

What the Fibra and pinna are.

The figure and the reason thereof.

This membrane which is indifferently hard hath growne up from the nerves of the fifth conjugation, which they call the auditory. But they were made thus into crooked windings, least the sounds rushing in too violently should hurt the sense of hearing. Yet for all this we oft find it troubled and hurt by the noise of thunder, Guns and Bels. Other wise also lest that the aire too sodainely entring in should by

For what use
the eare-waxe
serves.

its qualitys, as cold, cause some harme : and also that little creeping things and other extraneous bodys as fleas & the like, should be staied in these windings and turnings of the waies, the glutinous thicknes of the cholerick excrement or eare-waxe hereunto also conducing, which the braine purges and sends forth into this part, that is, the auditory passage framed into these intricate Mæanders.

*For the particular declaration
see D. Crookes Anatomic, pag.
577.*

For what use
the membrane
stretched un-
der the audito-
ry passage
serves.

But that we may understand how the hearing is made, we must know the structure of the organ or instrument hereof. The membrane which we formerly mentioned to consist of the auditory nerve, is stretched in the inside over the auditory passage like as the head of a Drum. For it is stretched and extended with the Aire, or auditory spirit implanted there, & shut up in the cavity of the mammillary processe and *foramen cecum*, that smitten upon by the touch of the externall aire entring in, it may receive the object, that is the sound, which is nothing else then a certaine quality arising from the aire beaten or moved by the collision, and conflict of one or more bodies.

What sound
is.

Such a collision is spread over the aire, as the water which by the gliding touch of a stone produces many circles and rings one as it were rising from another. So in rivelets running in a narrow channel, the water stricken and as it were, beaten back in its course against broken, craggy and steep rocks, wheels about into many turnings: this collision of the beaten aire flying back diverse waies from arched and hollow roofed

roofed places, as Dens, Cisterns, Wells, thick Woods and the like, yeilds and produces a double sound, and this reduplication is called an Echo. Wherefore the hearing is thus made by the aire, as a medium, but this aire is twofold, that is, externall and internall.

The cause of an echo.

The exterior is that which encompasses vs, but the interior is that which is shut up in the cavity of the mammillary proceffe and *foramen cecum*, which truly is not pure and sole aire, but tempered and mixed with the auditory spirit. Thence proceeds the noise or bearing of the Eares, when vapours are there mixed with the aire instead of spirits, whereby their motion or agitation is perturbed and confused. But neither doe these suffice for hearing, for nature for the more exact distinction of sounds hath also made the little bones, of which one is called the *Incus* or anvill, another the *Malleolus* or hammer, the third the *Stapes* or stirrop, because the shapethereof resembles a German stirrop. Also it may be called *Deltoides*, because it is made in the shape of the Greeke letter Δ.

The 3 bones of the auditory passage.

They are placed behind the membrane; wherefore the anvill and hammer moved by the force of the entrance of the externall aire, and beating thereof against that membrane, they more distinctly expresse the difference of sounds, as strings stretched within under the head of a Drum; as for example, these bones being more gently moved represent a low sound to the common sense & faculty of hearing, but being moved more vehemently and violently, they present a quick and great sound; to conclude, according to their diverse agitation, they produce diverse and different sounds.

Their use.

whence the difference of sounds.

The Glandules should follow the Eares in the order of Anatomy, as well those which are called the emunctories of the braine, that is, the *Parotides* (Which are placed as it were at the lower part of the eares) as these which lye under the lower Jaw, the muscles of the bone *Hyoides* & the tongue, in which the *Scrophule* and other such cold abscesses breed. It shall here suffice to set downe the use of all such like Glandules.

Therefore the *Parotides* are framed in that place by nature, to receive the virulent and malignant matter sent forth by the strength of the braine, by the veines and arteries spread over that place. The rest serve to strengthen the division of the vessels, to moisten the ligaments and membranes of the Jaw, lest they should be dried by their continuall motion. Their other conditions and uses are formerly handled in our first booke of Anatomy.

CHAP. XI.

Of the bone *Hyoides*, and the muscles thereof.

The Substance of the Bone *Hyoides* is the same with that of other bones, The figure thereof imitates the greek letter υ from whence it took the name, (as also the name *υψιλονειδης*; and from the letter λ it is in like sort called *λμβονειδης*; by some it is stiled *Os Gutturis* and *os Lingue*, that is, the Throat bone and Tongue bone. The composition thereof consists of many bones joyned into one by the interposition of gristles.

The reason of the name.

The composition.

This bone is bigger in beasts and composed of more bones, and that not only by the intercourse of gristles, but also of ligaments. It is seated with its basis (being gibbous on the forepart for constancy, and arched on the inside that it might receive and containe the root of the tongue) upon the upper part of that gristle of the throtle which is called *scutiformis* or Sheild-like, (for this seemes to prop it up by the strength of two proceffes rising at the basis thereof) and the root of the tongue. From this basis it sends forth two hornes to the sides of the tongue on each side one, which in men are tyed to the Appendix *styloides* by ligaments sent from it selfe. Contrary then it is in beasts, who have it of many bones united as we said, by the intercourse of ligaments even to the root of the *styloides*. Wherefore this bone hath connexion with the forementioned parts, and other hereafter to be mentioned. It hath the same temper as other bones have. The use of it is, to minister ligaments to certain muscles

The site.

The temper and use.

cles of the tongue, and insertion as well to the two foremost and upper muscles of the throat, as to its own, of which we will now treat.

The muscles
of the bone
Hyoides.

The muscles of the bone *Hyoides*, according to the opinion of some are eight, on each side four; of which there be two, one of which *Galen* refers to the common muscles of the *larynx* or throat; and the other to those which move the Shoulder-blade upwards. Howsoever it be, the first of the four before mentioned arises from the Appendix *Styloides*, and passing over the Nervous substance of the muscle opening the lower Jaw, is inserted into the horns of the bone *Hyoides*. This muscle is very thin, yet somewhat broad, the which in that respect may easily be cut, unless you have a care in separating the muscle which opens the lower Chap. The second ascends obliquely from the upper part of the shoulder-blade nere the production thereof called *Coracoides*, to the beginnings of the horns of the said bone *Hyoides*. This is round and nervous in the midst that so it might be the stronger, as that is which we formerly said opens the lower Jaw; and it is referred by *Galen* amongst those which move the shoulder-blade upwards. The third arises from the upper part of the *sternum*, and is inserted at the roote and basis of the bone *Hyoides*; yet *Galen* refers it to the common muscles of the *Larynx*; whose opinion takes place rather in beasts, than in man, seeing in man this muscle cannot be found either to proceed, or be inserted into the throat, as it is in beasts. The fourth and last descends within from the chin to the root of the bone *Hyoides*. The first of these muscles with its companion or partner moves the bone *Hyoides* upwards; the second downwards; The third backwards; and the fourth forwards. I would declare whence these muscles have their vessels, had I not abundantly satisfied that thing, when I treated of the distribution of the nerves, veines and arteries.

The action of
these muscles.

CHAP. XII.

Of the Tongue.

What kinde
of flesh the
tongue hath.

The quantity,

The figure.

Composure.

The nerves.

THE tongue is of a fleshy, rare, loose and soft substance; it enjoys flesh of a different kind from the rest of the flesh, as chiefly appears when you cut it from the first originall of the muscles thereof; which thing hath moved some, that they have made a fourth kind of flesh proper to the tongue and different from the rest, viz. the Fibrous, musculous, and that of the bowells. The quantity thereof is such that it may be contained in the mouth, and easily moved to each part thereof. The figure of it is triangular, which it rather expresses in the basis, which is at the root of the bone *Hyoides*, than in its point, or forepart, where from a triangle it becomes more dilated. It is composed of a membrane (which it hath from that which lines all the inside of the mouth) muscles 4. nerves two on each side, the one whereof is sent from the third conjugation, into the coat thereof; the other from the seventh is sent into the musculous substance even to the end thereof for motions sake; so that those sensifick nerves from the third conjugation onely give to judge of tastes, compose the coat, and touch or enter not the flesh. Besides it is composed of veines and arteries on each side one, which it receives from the externall Iugular and *Carotides*, running manifestly to the end thereof on the lower side, that so they might be easily opened in the diseases of the mouth and throat; they commonly terme these the *Vena nigra* or blacke veines.

The muscles
of the tongue.

The muscles of the tongue are absolutely ten, on each side five. The first narrow at the beginning, and broader at the end, descends into the upper side of the tongue from the Appendix *Styloides*, and together with its copartner drawes it upwards. The second hath its originall within from the lower jaw about the region of the Grinding teeth, and is inserted into the lower side of the tongue, the which with its partner drawes it downeward. The third proceeds from the inner part of the Chin and goes to the root of the tongue, that when need requires it may put it forth of the mouth. The fourth the greatest and broadest of them all, composed of

of all sorts of fibers, passes forth from the basis of the bone *Hyoides*, and ends at the lower part of the tongue, which with its companion plucks it backe into the mouth. The first & last most usually arises from the upper part of the hornes of the bone *Hyoides* and goes to the roots of the tongue betweene the two first, that it may move it to the sides of the mouth. The temper thereof, as of all other flesh, is hot and moist. The first action & commodity therof is, to be the organ of the sense of tasting, wherfore it was made fungous & spongy, that by reason of the rarity of it, it might more easily admit the taste conjoynd with the spittle, as a vehicle. Another to be an instrument to distinguish the voice by articulate speech, for which it was made movable into each part of the mouth. The third is to be a helpe to chew & swallow the meat. For which cause it is like a scoope or dish with which wee throw backe the corne into the mill, which hath scaped grinding. And because, when the tongue is dry, it is lesse nimble & quicke to performe its motions, as appears by those which can scarce speake by reason of thirst, or a burning feaver: therefore nature hath placed very spongy glandules at the roots therof, on each side one, which like sponges sucke and receive, both from the braine & other places a waterish and spittlesly humor, with which they humect and make more glib, not onely the tongue, but also the other parts of the mouth, as the throte and jawes; these glandules are called the *Tonsilla*, or Almonds of the throte.

The temper,
action, and
manifest use
of the tongue.

The use of the
glandules plac-
ed at the roots
of the tongue.

CHAP. XIII.

Of the Mouth.

THe mouth is that capacity which bounded with the cheekes & lips contains within its precincts the teeth, tongue, and the beginnings of the throtle and gullet. Therefore the use of the mouth is to containe the tongue, & serve it in the inter performance of its actions; & although many parts hereof have bin formerly handled, as the lips, teeth, lawes, tongue, almonds, & passages of the palate coming from the nose, yet it remaines, that we declare, what the palate, the *Gargareon*, or *Vvula* the *pharynx*, & *fauces* or Chops are. The palate (or as it is commonly called, the Roofe of the mouth) is nothing else but the upper part of the mouth bounded with the teeth gums & upper law. In which place the coate common to the whole mouth, is made rough with divers wrinkles, that the meats put up & down between the tongue & the Palate might be broken & chewed more easily by that inequality and roughnes. If any would finde the nerves, which descend into the palat from the fourth conjugation, let him separate that coat & cast it from the fore to the hind part of the mouth; for so he shal find them at the sides & hinde parts of the bones of the Palate, which incompass the palate, & at the beginning of the inner holes of the mouth, which descend from the nose, & region of the productions of the wedgbone called the Saddle. These holes or passages are open, that we may breathe the better when we sleep, & that when the nose is not well, the excrements which seeke their passage by it, may be easilier drawn away by the mouth. This same coate is woven with nervous fibers, that, like the tongue, it might judge of taste; these fibers compose a coat that hath a middle consistence betwixt soft & hard. For if it should have beene any harder, like a bone or gristle, it would have been without sense, but if softer hard, acride and sharpe meats would have hurt it.

What it is,
The use.

lat is.

The nerves
thereof.

Why the holes
of the palate
are open.

What kinde of
coate the pal-
lat hath.

CHAP. XIII.

Of the Gargareon, or Vvula.

BY the *Gargareon* we understand a fleshy & Spongy body, in shape like a pine apple, hanging directly down at the further end of the palate & basis of the bone *Ethmoides* where the two holes of the palate come from the nose, above the entrace of the throtle. This little body is scituate in this place, to breake the violence of the aire drawne in by breathing, & that by delay it might in some sort temper & mitigate it by the warmenesse of the mouth. Besides, that it might be as it were the *Pleatru*, or quill of the voice, so to diffuse the fuliginous vapour sent forth in breathing that it may be dispersed over al the mouth, that resounding from thence it may be articulate, & by the motion of the tongue distinguished & formed, into a certaine voice. Which use is not small, when we see by experience that such as have this particle cut away, or eaten or corrupted by any accident, have not onely their voyce vitiated and

of the *Vvula*.

depraved

What the
Pharinx and
fauces are.

depraved, but speake ill favouredly, and as they say, through the nose; and besides, in proesse of time they fall into a consumption by reason of the cold aire passing downe before it be qualified. This same particle, is also a meanes to hinder the dust from flying downe through the weazon into the Lungs. By the *Pharinx* and *fauces* is ment the inner & backe part of the mouth, set or placed before the entrance of the Throttle & Gullet; being so called, because that place is narrow & strait, that as it were by these straits, the aire drawn in by the mouth might be forced downe by the Throttle, and the meat into the Gullet.

CHAP. XV.

Of the *Larinx* or Throttle.

What is ment
by the *Larinx*.

The magni-
tude, figure
and composi-
ture.

The descripti-
on of the
3 gristles of
the *Larinx*.

Whence the
infinite variety
of voyces pro-
ceed.

The muscles
of the *Larinx*.
Their number

A notable
history.

Ifst we must shew what is ment by the *Larinx* or throttle, then prosequite the other cōditions of it after our accustomed maner. Therfore by the *Larinx* we understand nothing els in this place, than the head & extremity of the rough Artery, or weazon, which comes neerer to Gristlely substance, then to any other. The quantity therof is sufficiently large, yet divers according to the diversity of bodies. It resembles in shape the head of a Germane pipe. The composure of it consists of 18. muscles, on each side nine, which as they are like in quantity, so also in strength & action; of three gristles, veines, arteries and nerves, as we shewed, when we spoke of the distribution of the vessels; as also of a double coate, the one externall, the other internall, as we shewed when we spoke of the weazon. These three Gristles are joyned together by certaine Ligaments & muscles; the formost gristle, which also is the greater is called by the Greekes *βυσσινος*, in Latine commonly *Scutiformis*, that is sheild-like, because it resembles a sheild. The second being the hinder and middle in magnitude, wants a name, wherfore it is called the *innominata* or nameles gristle. The last & least which notwithstanding may be parted into two, so lyes upon the edges of the other, that it resembles the mouth of an oyle pot, or a pitcher, wherupon the Greekes call it *Arytenoides*. These gristles thus fitted amongst themselves utter a distinct voice, by the benifit of the *Epiglottis*, or After tongue, & also of the muscles opening & shutting, dilating & cōpressing them, whence proceed infinite varieties of voyces. For thus when they are opened and dilated they yeeld a heavy, or dull sound; when they are shut or drawn together, a quick, or sharpe sound, and to conclude, they make it infinite wayes different according to the infinite variety of the dilatation, or constriction thereof. Therfore because it was fit these gristles should be moveable, especially the *Arytenoides*, & *Thyroides*, nature hath put to them on each side 9 muscles, of which three are common and 6 proper. The first of the common lying hid under the third muscle of them that move the bone *Hyoides*, arises from the root of the same bone, & by an oblique descent inserts it selfe at the basis of the shield-like gristle, to dilate it upwards & downwards. The second ascends obliquely from the inner part of the *sternon* according to the length of the weazon (whence it is called *Bronchius*) to the bottom & sides of the same shield-like gristle, that it may open and dilate it with its wings. This muscle is seen from the first originall therof, even a great part of the way straitly to cohere with the third muscle of the bone *Hyoides*; therfore under each of the muscles, there is a glādulous body spread about the fore & upper part of the weazon, on that place where it applies it selfe to the throttle; this body although it resemble a fleshy substance, yet it is a glandule, which being pluckt away by a certaine Emperike taking upon him to cure the kings evil, caused a defect of voice on one side, because he pulled away the recurrent nerve lying upon that glandule as it goes to the throttle, as *Galen* reports, *Lib. de locis affectis*. The third & last arises from the part of the *Vertebra's* of the neck lying transversly upon the sides of the gullet, & ends at the wings & sides of the shield-like gristle, that it may tye it more straitly to the second Gristle. But these three are called cōmon muscles, because they take their original from some other place than the throttle that so they may be inserted into some part therof; for they are called the proper muscles which arise from the Throttle it self, which we have said to be 6. on each side. The first of which arising from the fore part of the second gristle, makes a circle under the basis of the shield-like gristle; whilest ascending obliquely to the basis therof, it is afterwards inserted in a part of it, so to strengthen and dilate it. The second in like manner arising

arising from the second gristle, from that place where it adheres to the first, it runnes obliquely crossing the first to the inner and forepart of the gristle *Thyroides* neere to the basis thereof, that it may joine it to the second. The third from the hinde basis of the second gristle ascends directly to the basis of the third gristle *Arytenoides*, that with the second muscle it may open & shut it. The fourth ascends from the sides of the second gristle, neere the originall of the second muscle, to the sides of the *Arytenoides*, that with the second muscle it may open and shut it. The fift arises from the inner middle of the sheild-gristle, and ends in the fore part of the *Arytenoides* at the insertion of the fourth muscle, that so it may presse down the said gristle.

The sixt and last ascends by the hinde basis of the *Arytenoides* to the fore basis of the same, to presse it downe. But you must note, that all such muscles, as arise from below upwards, receive branches from the recurrent, but especially those who open and shut the gristle *Arytenoides*. But the site, tempre connection, and use of the throtle may easily be knowne by that we have said before: Although it be a thing very full of difficulty to search out and demonstrate all the conditions of the organically parts, by reason of the diversitie of their composition. Wherefore hence forward concerning the substance, temper, and other circumstances of such parts as we shall omit; you may have recourse to those things which we have written in the Demonstration of the simple and simular parts, of which these organically are composed; as if any should aske of what temper the *Larinx* is, you shall answere, of a colde, dry, and hot, and moist, because it consists both of a gristlely and fleshy substance. Hee which reckons up all the parts of the mouth, must not omit that gristlely and membranous body which arises from the roots of the tongue, which that it might be more quicke for motion, that is, whereby it might be more easily erected and depressed (for those things which are more soft doe continually slide away, but those which are too hard cannot be bended) it was convenient it should be neither too hard nor too soft, that it might be erected whilest we breath, but depressed when wee swallow. It is a principall instrument of the voyce, for it cannot be well articulated unlesse the way were strait. Therefore it straitens that way, and the passage of the gristles of the throtle, but specially the *Arytenoides*; it is alwayes moist by a certaine native, and inbred humiditie; wherfore if it happen to be dried by a fever, or any other like accident the speach is taken away. It is bound on both sides by the common membrane of the mouth to the sides of the *Arytenoides* even to the backe part thereof, that so like a cover it may open and shut the orifice of the throtle, that none of the meat and drinke in swallowing may fall into the weazon, in such abundance as may hinder the egress and regresse of the aire. For we must not thinke that this body doth so closely shut the orifice of the throtle, but that some small quantitie of moisture alwayes runnes downe by the inner sides, as the walles thereof, to moisten the lungs; otherwise *Eclegma's* should be of no use in the diseases of the Chest. And because that this litle body is partaker of voluntarie motion, therefore according to the opinion of some there are foure muscles bestowed upon it, two which may open it and two that shut it, on each side one. The opening muscles descend from the roote of the bone *Hyoides*, and in their insertion growing into one they are terminated in the roote of this body, that is, the *Epiglottis* in the backe part thereof. The shutting muscles (in those creatures where they are found) arise on the inside betweene the coate & gristle thereof. Truly I could never observe and finde these foure muscles in a man, though I have diligently and earnestly sought for them, but I have alwayes observed them in beasts. Therefore some have boldly affirmed that this litle body in swallowing lyes not upon the orifice of the Throtle, unlesse when it is pressed downe by the heaviness of such things as are to be swallowed; but that, at all other times by reason of the continuall breathing it stands upright, the Throtle being open. There remaine as yet to be considered, two small bosomes, or cavities, or rather fissures which nature hath hollowed in the very throtle under the *Epiglottis*, on each side one, that if by chance any of the meat or drink should fall, or slip aside in the *Larinx*, it might be there stayed & retained. Beside that, the Aire too violently entring, should be in some sort broken by these clifts, or chinkes, no otherwise than the blood and spirit entring into the heart through the *Auricle* or Eares thereof.

Whence the muscles of the Throtle have their nerves.

The *Epiglottis* or *Apera* tongue,

Of petable things comes what alwayes falls upon the Lungs.

The muscles of the *Epiglottis*.

The use of the cavities or fissures of the Throtle.

CHAP. XVI.

Of the Necke and the parts thereof.

Ifst we will define what the neck is, then prosecute the parts thereof as well proper, as common, especially those of which we have not as yet treated. For it were superfluous to speake any more of the skin, the fleshy pannicle the veines, arteries, nerves, gullet, weazon & muscles ascending & descending to the parts into which they are inserted amongst the necke; wherefore you must not expect that we should say any thing of the neck, more than to describe the *Vertebra* or rack-bones, being the proper parts thereof, & the ligaments as well those proper to the neck, as those which it hath in common with the head; & lastly the muscles, as well those it hath in common with the head & chest, as those of its own. Therefore the neck is nothing els, then a part of the head, which is contained between the nower bone & the first *vertebra* of the back. First in the neck the *Vertebra's* must be considered, & we must shew what they have proper & peculiar, & what common amongst themselves, that we may the more easily shew the originall and insertion of the muscles growing out of them & ending in them. The neck consists of seven *Vertebra* or Rack-bones, in which you must consider their proper body; and then the holes by which the spinall marrow passes; thirdly the *Apophyses* or processes of the *Vertebra*; fourthly the holes through which the nerves are disseminated into other parts from the spinall marrow, & besides the perforations of the transverse productions by which the veines, & arteries which we call *Cervicales* ascend amongst the necke, & lastly the connexion of these same *vertebra* or Rack-bones. For the first, by the body of the *vertebra*, we understand the forepart thereof upon which the gullet lyes. For the hole, that is not alwaies the largest in those *vertebra* which are highest the head; but it is alwayes encompassed with the body of the *vertebra*, & besides with three sorts of processes, except in the first Rack-bone, that is right, transverse & oblique. By right we understand these extuberancies in the Racke-bones of the necke which are hollowed directly in the upper part of them & rise up crested on each side to susteine and receive the basis of the Rack-bone which is set upon it. By the oblique processes, wee understand the bunchings out by which these Rack-bones are mutually knit together by *Ginglymos*; these are seated between the right & transverse processes. By the transverse we understand the protuberations next the body, which divide the *Vertebra* or Rackbone in a straight line. These processes are perforated that they may give way to the before described veines & arteries, which entering the Spinall marrow by the holes of the nerves nourish the Racke-bones & parts belonging to them. Besides you must note that the perforations of the Rack-bones of the neck by which the nerves proceed from the spinall marrow to the outward parts, are under the transverse processe, that is growing or made by the upper & lower *vertebra*, contrary to all the other which are in the rest of the Rack-bones. For the connexion of the Rack-bones, you must know that all the *Vertebra* of the spine have six connexions, two in their own bodies, and 4 in their oblique processes. By the two first connexions they are so mutually articulated in their owne bodies that each are joyned with other both above and below. But by the 4 other, by their oblique ascendent & descendent processes, on each side 2, they are so mutually inarticulate that as the fourth Rack-bone of the neck by its oblique ascendent processes, is received of the descendent processes of the third Racke-bone; so it receives the oblique ascendent processes of the first, by its oblique descendents, for alwayes the oblique ascendents are received, and the descendents receive. Yet wee must except the first Rack-bone of the neck which is contained with 4 connexions by his lower oblique processes, & by its upper by which it receives the oblique processes both of the nower bone, & of the second Rack-bone. The second *Vertebra* or Rack-bone must also be excepted which is holden by 5 connexions, that is to say, foure by its oblique processes, & the fifth by its own body, by which it is knit to the body of the third *Vertebra*. But we must note, that whereas nature hath not given a Spine to the first Rack-bone, yet it hath given it a certaine bunch or extuberancy instead thereof; in like manner, seeing it makes no common passage with the second *Vertebra* for the passage forth of the nerve, it is perforated at the sides of its body, and it is made very thin on the fore side, as if it were without body, that it might receive the fore processe raised in the upper body of the second Racke-bone,

What the necke is.

What to be considered in the *vertebrae* of the necke.

Which be the right processes of the *vertebra*.

Which the oblique.

Which the transverse.

The connexions of the *vertebra* of the necke.

The processes called the tooth.

Racke-bone, which Hippocrates calles the tooth, to which the principall Ligament of the head is fastened, which descends within from the hinde part of the head under the *Apophyses clinoides* or processs of the wedge bone.

Table 20. Figure 1. Sheweth all the racke-bone of the backe knit together.
Figure 2. Sheweth the fore and upper face of the necke, &c. See D. Crooke, pag. 398.

FIG. I

From, A, to B, the seven
vertebres of the necke;
From C, to D, The twelve
vertebres of the chest.
From E, to F, The five
rack-bones of the
Loynes.
From G, to H, The Os
sacrum or Holy-bone
consisting commonly
of 6. vertebra.
From I, to K, The bone
Coccyx or the rump-
bone according to the
late writers.
LL, The bodies of the
vertebra.
M, The transverse pro-
cesses of the vertebra.
N, The descendent pro-
cesses.
OO, The ascendent pro-
cesses.
PP, The backward pro-
cesses.
QQ, The holes that are
in the sides of the ver-
tebra through which
the nerves are trans-
mitted.

RR, A gristly Ligament betwixt the vertebra.
A, 2, 3, 4, The hole whereout the marrow of the backe issueth.
B, 2, 3, The cavity which admitteth the root of the second rack-bone.
C, 3, 4, A cavity or Sinus in the same place crusted over with a gristle.
D, 2, A prominence in the outward region of this Sinus.
EF, 2, 3, The Sinus or cavity of the first racke-bone which admitteth the 2. heads of
the nowle-bone.
GG, 2, 3, 4, the transverse proceffe of the 1. Vertebra.
H, 1, The hole of this transverse proceffe.
I, 2, The Sinus, which together with the cavity of the nowle-bone marked with E,
maketh a common passage prepared for the nerves.
K, 3, 4, A rough place where the spine of the first racke is wanting.
LL, 4, Two cavities of the first racke receiving the 2. bunches of the second racke
marked with MN.
MN, 5, 6, The 2. bunches of the second racke which fall into the cavities of the first.
O, 7, The appendix or tooth of the second racke. P, 5, A knub of this appendix crusted
over with a gristle. Q, 6, The backside of the tooth. R, 6, the Sinus or cavity of the
same, about which a transverse Ligament is rowled containing the said tooth in the
cavity of the first racke. ST 6, Certaine cavities at the sides of the tooth whence the
roots issue of the fore-branch of the second paire of sinews. V, 5, the point of the
tooth. X, 3, An asperity or roughnesse where is a hole but not thrilled through. Y, 6, A
cavity

cavity of the second racke which together with the cavity marked with Z, maketh a hole, through which the nerves doe issue. Z, 4, the *Sinus* of the first racke. a, 5, 6, 7, the double spine of the second racke. b, 5, 6, 7, the transverse proceffe of the second rack. c, 7, the hole of the said transverse proceffe. d, 6, 7, the descending proceffe of the second rack whose cavity is marked with d, in the 6. figure. e, 6, 7, the place where the body of the second rack descendeth downward. f, gg, 8, the lower side of the body of the third rack at f, the two eminent parts of the same at gg. hi, 8, the ascending proceffes. l m, 8, the two descending proceffes. n o p q, 8, the transverse proceffes. r, 8, 9, the spine or backward proceffe. st, 8, the two toppes of the spine. u, 9, the descending proceffe of the third rack. x, 9, the ascending proceffe. y, the transverse proceffe of the third rack. z, 8, 9, the hole of this transverse proceffe. b, 9, the upper hollowed part of the body of the third rack. d, 9, the *Sinus* or cavity which maketh the lower part of a hole through which the conjugations of the nerves are led. e, 7, the upper part of the same hole.

By what articulation the head is bended backwards and forwards

And by this articulation the head is bended forewards and backwards, as it is moved to the sides by the articulation of the first Racke-bone with the second. That proceffe is bound by two Ligaments, the first of which being the greater and broader is externall, comprehending in the compasse thereof all the upper articulation, ascending from the Racke-bones to the head, or rather descending from the head to them, as any other Ligament going from one bone to another; The other is the stronger and also encompasses the articulation mixing its selfe with the gristle, which by its interposition binds together all the Racke-bones, the first excepted, as you may see in pulling asunder the Racke-bones of a Swine; and the whole Spine or Backe-bone is tyed together and composed throughout with such Ligaments.

The Vertebra of the Holy bone.

The Holy bone is composed of 4. *Vertebra* [or rather of five, or sixe, as in the figure following] Besides the Rumpe-bone, it receives, and holds fast the *Ossa Ilium*, or Hanch-bones, and is as a *Basis* to all the Racke-bones placed above it, whereby it comes to passe that the Racke-bones from the head to the Holy-bone grow still thicker, because that which supports ought to be bigger than that which is supported. There is a certaine moisture, tough and fatty, put between the Rack-bones, as also in other joints, to make them glib and slippery that so they may the better move. Whilest this motion is made, the Racke-bones part one from another.

The manifold uses of the backebone.

The commodities or uses of the Spine are said to be foure. The first is, that it is, as it were the seat and foundation of the composure and construction of the whole body, as the Carkasse is in a ship. The second, that it is a way or passage for the marrow. The third is, because it containes and preserves the same. The fourth is, that it serves for a wall or bulwarke to the entrailes which lye and rest upon it on the inside. And because we have fallen into mention of Ligaments, it will not be amisse to insert in this place, that which ought to be knowne of them. First therefore we will declare what a Ligament is, then explaine the divers acceptions thereof, and lastly prosecute their differences.

What a Ligament is.

Therefore a Ligament is nothing else than a simple part of mans body, next to a bone and Gristle the most terrestriall, and which most usually arises from the one or other of them either mediately or immediatly, and in the like manner ends in the one of them, or in a Muscle, or in some other part; whereby it comes to passe that a Ligament is without blood, dry, hard, and cold and without sense, like the parts from whence it arises, although it resemble a Nerve in whitenesse and consistence, but that it is somewhat harder.

Why it is without sense.

What parts may be called Ligaments in a generall signification.

A Ligament is taken either generally, or more particularly; in generall, for every part of the body, which ties one part to another, in which sense the skin may be called a Ligament, because it containes all the inner parts in one union. So the *Peritonaeum* comprehending all the naturall parts, and binding them to the backe-bone; so the membrane investing the Ribbs, (that is the *Pleura*) containing all the vitall parts; thus the membranes of the braine, the nerves, veines, arteryes, muscles, membranes, and lastly all such parts of the body, which bind together and containe other, may be called Ligaments, because they binde one part to another; as the nerves

annexe

annexe the whole body to the braine, the Arteries fasten it to the heart: and the veins to the liver. But to conclude, the name of a Ligament more particularly taken, signifies that part of the body, which we have described a little before.

The differences of Ligaments are many, for some are membranous and thin; others broad, other some thicke and round, some hard, some soft, some great, some little; some wholly gristlely, others of a middle consistence betweene a bone and a gristle, according to the nature of the motion of the parts, which they binde together in quicknesse, vehemency and slownesse. We will shew the other differences of Ligaments, as they shall present themselves in dissection.

The differences of Ligaments properly so called.

CHAP. XVII.

Of the Muscles of the Necke.

He Muscles of the necke as well proper as common, are in number twenty, or else twenty two, that is, ten, or eleven on each side; of which seven only move the head, or the first vertebra with the head; the other 3 or 4, the necke it self. Of the 7 which move the head, & with the head the first Vertebra, some extend & erect it, others bend and decline it, others move it obliquely, but all of them together in a successive motion move it circularly; and the like judgement may be of the Muscles of the Necke.

The fourth Figure of the Muscles. This Figure sheweth the cavities of the middle and lower bellies, the bowels being taken out, but most part of the bones and muscles remaining.

AB, The first muscle bending the necke called *Longus*.

CC, The second bender of the necke called *Scalenus*.

DDDD, The outward intercostall muscles.

EEEE, The inner intercostall muscles.

FFF, The second muscle of the chest called *serratus maior*.

G, The first muscle of the shoulder-blade called *serratus minor*, separated from his originall.

H, The first muscle of the arme called *Pectoralis*, separated from his originall.

I, The second muscle of the arme called *Deltoides*.

K, The bone of the arme without flesh.

L, The first muscle of the cubite called *Biceps*.

M, The second muscle of the cubit called *Brachialis*.

N, The clavicle or collar-bone bent backward.

O, The first muscle of the chest called *subclavius*.

P, The upper proceffe of the shoulder-blade. Q, The first muscle of the head called *obliquus*

obliquus inferior. R, The second muscle of the head called *Complexus*. S, The fourth muscle of the shoulder blade called *Levator*. TV, The two bellies of the fourth muscle of the bone *Hyeis*. XX, aa, The first muscle of the backe whose originall is at aa. TT, bb, cc, The first muscle of the thigh called *Psoa*, whose originall is at cc, and tendon at bb. ZZ, The seventh muscle of the thigh. d, the holy bone. ooo, the holes of the holy bone out of which the nerves doe issue. e, A portion of the first muscle of the thigh arising from the share-bone. f, the share-bone bared. k, the ninth muscle of the thigh or the first *circumactor*.

The fifth Figure of the muscles in which some muscles of the head, Chest, arme, and shoulder-blade are described.

- 1, The proceſſe of the ſhoulder-blade, called the top of the ſhoulder.
- O, The fourth muscle of the arme or the greater round muscle, to which *Fallopian* his right muscle is adjoyned, which ſome call the leſſer round muscle.
- Q Q, The first muscle of the arme or the upper blade rider.
- X, The second muscle of the ſhoulder-blade or the *Levator* or heaver.
- Z, the second muscle of the chest or the greater *Saw* muscle.
- r, the fifth muscle of the chest or muscle called *Sacrolumbus*.
- αβ, His place wherein he cleaveth faſt to the longeſt muscle of the backe.
- γγ, the Tendons of the muscle obliquely inſerted into the ribs.
- ΔΔ, the first paire of the muscles of the head or the Splinters.
- Ch. 8. 9, their length whose beginning at 8 and inſertion at 9.
- 10, 11, the ſides of this muscle.
- 12, that diſtance where they depart one from the other.
- 13, the two muscles called *Complexi*, neare their inſertion.
- φ, the second muscle of the backe or the Longeſt muscle.
- Ω, the fourth muscle of the backe or the *Semi-spinatus*.
- ς, the ſhoulder-blade bare.
- P, A part of the tranſverſe muscle of the Abdomen.

But before I can come to the deſcription of their originall and inſertion, I muſt admoniſh thee, that the 2 Muscles of the ſhoulder-blade muſt firſt be taken away by diſſection; that is, the *Trapezius*, or Table-muscle, and the *Rhomboides*, or ſquare-muscle; whose originall and inſertion that we may the better demonſtrate, (or rather the action by which wee ſeek that originall and inſertion,) they muſt be pulled up, beginning at their inſertion, which is at the ſhoulder-blade (as ſhall be ſhewed in the proper place) turning them up towards their originall, that is, to the Spine. Beſides the leſſe *Rhomboides*, the hinder, and upper (called alſo the *Dentatus* or toothed-muscle) muſt be raiſed from its originall, which is at the three lower Rack-bones of the Necke and the firſt of the backe, and turned up to its inſertion

inflection, which is at three spaces of the lower ribs nigh to the hinde, and upper angle of the shoulder-blade, as shall be shewed in fit place hereafter. These muscles thus raised up, the 4 muscles which erect and extend the head must be taken away, and then those two which move it obliquely, and lastly one which bends, or de-

The sixth Figure of the muscles, shewing some of the muscles of the Head, Backe, Chest, Shoulder-blade and Arme.

AD, the second paire of the muscles of the head, or the two *Complexi*, the first part is at *AD*.

BC, the second part. *EF*, the third part rising up under *G* and inserted at *F*.

G, the fourth part of this muscle or the right muscle of the head according to *Fallopian*, which *Vesalius* made the 4. part of the 2.

GG, (Betwixt the ribs) the externall *Intercostall* muscles.

Z, the originall of the 2. muscle of the backe.

M, His tendons at the racke-bone of the necke.

The upper *O* the fourth muscle of the arme or the greater round muscle.

OO, the lower, the 6 muscle of the chest, or the *Sacro-lumbis* hanging from his originall.

Q, the sixt muscle of the arme or the upper *Bladerider* inverted.

V, the third ligament of the joynt of the arme:

X, the fourth muscle of the shoulder-blade or the *beaver*.

Z, the second muscle of the Chest or the greater *Saw-muscle*.

z, the 3. muscle of the necke called *Transversalis*. *π*, the 4. muscle of the necke called *Spinatus*. *Σ*, the first muscle of the backe or the *Square muscle*. *φ*, the 2. muscle of the backe or the *Longest*, whose originall is at *Z* and his tendons at the *Vertebra* at *M M*. *δ*, the fourth muscle of the backe called *Spinatus*. *δ*, the backe of the shoulder-blade flaid,

clines, for thus anatomically order requires. Yet if you thinke good, you may, not hurting the other, first of all cut away that which is called the *Mastoides*, which declines or bends the head. For these 4, which lift up and extend the head, the first from the figure of the *Splenie* is called the *Splenius*, it ascends from the 5. upper spines of the backe and the 4 lower of the necke, and is obliquely inserted at the backe part of the head and the mammillary processe, whence you may raise it towards its originall. The second by reason of its composure is called *Complexus*, this passing from the third, fourth and fifth transverse processe of the Backe and often from the first of the Necke, ascends directly to the backe part of the head

The Splenius.

The Complexus.

The Recti, or
2 right mus-
cles.

head, encompassing the lower and side part of the necke, you may easily take it up; if you begin at the spine, and so goe forwards to the transverse processes and mammillary processes of the nower bone. This *Complexus* may be divided into two or three muscles, but that with some difficulty, by reason of its folded texture. The third and fourth, which be two of the eight little muscles, being foure on each side, doe ascend somewhat obliquely, the first truly from the whole side of the second *Vertebra*. The second from the whole side of the proceffe of the first *Vertebra*, which it hath in stead of a spine; they ascend to the backe part of the head just against the spine; these two muscles by the consent of all Anatomists are called right, or direct muscles, only moving the head: these truly must not be pluckt from the places of their originall, nor insertion, but onely bound by a string put under them, that so they may be the more easily shewed. On each side follow two oblique muscles, one whereof

The seventh Figure of the muscles; shewing some muscles of the head and Chest, the Trapezius or Table-muscle being taken away: as also of the blade and arme.

A, The prominent part of the fourth muscle of the chest called *Serratus posterior superior*.

Δ, the first muscle of the head called *Splenius*.

EE, the insertion of the second muscle of the head called *Complexus*.

I, the collar bone bared.

M, the backpart of the second muscle of the arme called *Deltoides*.

ζH, His backward originall.

θ, His implantation into the arme.

NN, the fourth muscle of the arme called *Latissimus*.

σμ, His originall from the spines of the rack-bones and from the holy bone

ω, the connexion of this muscle with the hanch-bone, which is led in the inside from μ to ω.

ω, the place where it lieth upon the lower angle of the Basis of the shoulder-blade.

O, the 4. muscle of the

arme called *Rotundus maior*. e, some muscles of the backe doe here offer themselves. P, the fift muscle of the arme called *Suprascapularis Inferior*. Q, the sixt muscle of the arme called *Suprascapularis Superior*. S, the beginning of the third muscle of the arme called *Latissimus*. V, the third muscle of the blade called *Rhomboides*. φ X, His originall from the spines of the rackebones. φ ω, His insertion into the basis of the shoulder-blade. ζ, the fourth muscle of the blade called *Levator*. * A part of the oblique descendent muscle of the *Abdomen*.

onely moves the head: the other primarily the first *Vertebra*, but secondarily, and by accident the head it selfe. For the first, contrary to the opinion of some, it arises from the transverse proceſſe of the first rack-bone, and then is inserted, above the insertion of the first right muscle, the which in like manner you must lift up, by some thing put underneath it, but not separate it. The other entering forth of the spine of the second *Vertebra*, is inserted at the proceſſe of the first, contrary to the originall of the precedent, although some thinke otherwise. It will be convenient in like manner onely, to lift up this with a string, and not plucke him from his place, that so you may see how all these make a perfect triangle. The action of this muscle is contrary to the action of the precedent, as the contrariety of its originall and insertion shew:

The eight Figure of the muscles; especially of those of the Chest, Head, and Shoulder blade, the Trapezius, Latissimus, and Rhomboides, being taken away.

A, The fourth muscle of the chest, or the upper and hinder Saw-muscle.

B, the 5 muscle of the chest, or the lower and hinder Saw-muscle.

a, b, A membranous beginning of the muscle of the *Abdomen*, descending obliquely downe from the spine of the backe.

C, the first muscle extending the Cubit at *r*, his originall is from the necke of the arme, and from the lower basis of the blade at *d*.

E, the originall of the fourth muscle of the bone *hyois* from the blade.

GG, the outward intercostall muscles.

I, the Clavicle or collar-bone bared.

N, the upper, the second muscle of the arme called *Deltoides*, char.

4, 5, the beginning of this muscle.

N, the third muscle of the arme or the broad muscle separated.

O, the fourth muscle of the arme or the lower *Super-Scapularis* or bladerider.

1, 2, 3. Char. His originall at the

basis of the shoulder-blade at *1, 2*, and his insertion into the joynt of the arme at *3*. *Q*, the sixt muscle of the arme or the upper *Super-Scapularis*. *X*, the fourth muscle of the blade called *Levator* or the heaver. *Z*, the second muscle of the Chest or the greater Saw-muscle. *7, 7*, Char. the ribs. *r*, the sixt muscle of the chest, or the muscle called *Sacrolumbus*. *Λ*, the first muscle of the head or the splinter. *EE*, the second muscle of the head or the insertion of the muscles called *complexi*. *a*, the second muscle of the backe or the longest muscle. *α*, the fourth muscle of the backe called *Semispinatus*.

Wherefore

Which may be truly called the proper muscle of the necke.

The two motions of the head,

Wherefore when the first oblique moves the head obliquely forwards, the second pulls it packe by the first *Vertebra*, this with his associate of the other side, may be truly termed the proper muscles of the neck, because they belong to no other part; whereas it is contrary in other muscles. But we must note, that the head (according to *Galens* opinion) hath two motions, one directly forwards and backwards, as appears in beckning it forwards, and casting it backwards; the other circular.

The first in *Galens* opinion is performed by the first *Vertebra* moved upon the second; the second by the head moved upon the first *Vertebra*; for which he is reproved by the latter Anatomists, who teach that the head cannot be turned round or circularly upon the first *Vertebra* without putting it out of joynt.

For the last, which bends the head, it ascends from the upper and side part of the *Sternon*; and the next part of the clavicle, obliquely to the *Apophysis*

The ninth Figure of the muscles, shewing the muscles of the Head and Necke.

AB, the third paire of the Muscles of the head called *Recti Maiores*.

C, the Mammillary proceffe.

D, the transverse proceffe of the first rackebone.

E, the proceffe of the 2 rackebone of the necke.

FG, the fourth paire of muscles of the head called *Recti Minores*.

HI, the fift paire of muscles of the head called *Obliqui Superiores*.

KL, the sixt paire of muscles of the head called *Obliqui Inferiores*.

X, the fourth paire of muscles of the shoulder-blade.

A, the second muscle of the necke called *Scalenus*, which *Falopius* maketh the eight muscle of the chest.

π, the fourth muscle of the necke called *Spinatus*.

Σ, the first muscle of the backe called *Quadratus*.

ϕ, the second muscle of the backe called *Longissimus*.

a, the sinus or bosome of this muscle; whereby it giveth way unto the third muscle of the backe, called *Sacer*.

b, His Originall.

ψ, the third muscle of the backe cal-

led *Sacer*. *γ*, His Originall. *δ*, His end. *ω*, the fourth muscle of the backe called *Semispinatus*. *ε*, His upper end under the fourth muscle of the necke.

Mastoides or mammillary proceffe of the hinde part of the head, whence it is called the *Mastoides*. You may divide this by reason of its manifold originall rather into two, than into three muscles. But it had beene better that the head might have beene moved every way, equally backwards and to the right and left sides; but thus it would often have beene strained to our great dammage and danger of life; neither could there have beene such facility of motion without a loosensse of the joynt. Therefore nature had rather bestow upon the head an harmelesse facultie of fewer motions, than one furnished with more variety, but with a great deale more uncertainty and danger. Wherefore it hath made this juncture not lax or loose, but stiffe and strong.

After

The *Mastoides*.

After the shewing of these muscles, we must come to three or foure of the necke, of which number two (which some reduce to one) extends, another bends, and the last moves side wayes, and all of them with a motion succeeding each other turne it about, as we said of the muscles of the head. The first of these which extend, taking its originall from the fixe transverse processes of the fixe upper racke-bones of the backe, or rather from the root of the oblique, ascends directly to the spine of the second *Vertebra* of the necke, and the oblique processe thereof; some call it the *Transversarius*; that is, the transverse-muscle. This, if you desire to take it away, it is best first to separate it from the spine, then to turne it upwards to the transverse processes; unlesse you had rather draw it a little from its partner and companion in that place where their originals are distinct, seeing it is the last and next to the bones.

The Trans-
versarius.

Marvell not, if you finde not this distinction of their originall, so plaine and manifest, for it is commonly obscure. For the muscle *Spinatus*, as it most commonly comes to passe, arising from the roots of the seven upper spines of the backe, and the last of the necke, is inserted into other spines of the necke, so that it might easily be confounded with the former by *Galen*. The third bends the necke, and arising within from the body of the five upper *Vertebra* of the backe (though with a very obscure originall, specially in leane bodies) it ascends under the gullet alongst the necke, even to the nowle-bone, into whose inner part it is obscurely inserted. Wherefore it is likely that it helps not onely to bend the necke, but also the head. This muscle is made of oblique fibers proceeding from the body of the *vertebra*, all the way it passes to the transverse processes of the other *Vertebra*. But it seemes with its copartner which is opposite to it, to make a certaine hollow path upon the bodies of the *Vertebra*, to the gullet, and it is called the long muscle. The fourth and last, which we said moves the necke to one side, is called *Sclenius* from the figure thereof; it ascends from the hinder and upper part of the first rib of the Chest, inserting its selfe into all the transverse processes of the necke by its fibers, which as it were for the same purpose, it hath sufficiently long, that it may fasten it selfe from the furthest or lowest processe of the necke into the first or highest thereof. The passage of the nerves through this to the arme makes this muscle seeme double or divided into two. For the veines and arteries pertaining to the necke, they have beene declared in the proper Chapters of the distributions of the vessels; it remaines that you note, all these muscles receive nerves from the *Vertebra* whence they arise.

The *Spinatus*.

The *Longus*.

The *Sclenius*.

CHAP. XVIII.

Of the Muscles of the Chest and Loynes.

WE must now speake of the Muscles both of the Chest which serve for respiration, as also of the Loynes. But first we must know that the hinder part of the Chest called the *Metaphrenum*, or backe, consists of twelve *Vertebra*, the loynes of five, all which differ not from the *Vertebra* of the necke, but that they are thicker in their bodies than these of the necke; neither are they lesser in holes, neither they have their transverse processes perforated, or parted in two, as the racke-bones of the necke have. Besides each of these racke bones alone by it self, on each side in the lower part thereof makes a hole, through which a nerve hath passage from the spinall marrow to the adjacent parts, when on the contrary in the *Vertebra* of the necke, such holes or passages are not made, but by meeting together of two of them.

In what the
Vertebra of the
necke and
loynes agree
and disagree.

Concerning the processes of the Rackbones of the Chest, whether transverse, right or oblique, they differ nothing from these of the necke (I meane even to the tenth) but that the transverse seeing they are not perforated, as we said before, do as it were sustaine the ribbes, being straitly bound to them with strong ligaments both proper and common; but after the tenth *Vertebra* of the backe, the two other of the backe, and all those of the loynes are different, not onely from those of the necke, but also from the tenth first of the backe, by reason of their oblique processes, because from

the eleventh (which is received, as well by that which is above it, as by that under it, for the strength of the whole backe, and the easier bending thereof without feare of fracture or dislocation) the above mentioned processes of the lower rack-bones which were wont to receive, are received; as on the contrary they receive which were wont to be received. They differ besides from all the forementioned, by reason of their spines, because from the eleventh they beginne by little and little to looke upwards, contrary to the former.

How the tenth Vertebra of the backe, may be said to be the middle of the spine.

But if any aske, how the tenth Vertebra of the backe may be termed the midst of the spine, being the whole spine consists of twentie foure Vertebra? He may know that this may be true, as thus; if the sixe bones of the holy-bone, and the fourth of the Rump (being more gristlely than bony) be numbred amongst the bones of the Spine; for then from the setting on of the head to the eleventh racke bone of the backe, are seaventeene in number, and so many from thence downewards.

The number of the muscles of the Chest.

But let us returne to the muscles of the Chest serving for respiration. First, you must know that these Muscles are fourescore and nine, that is, on each side forty foure, alike in strength, thickeesse, site, and action; and one besides in the midst which they call the *Diaphragma* or Midriff.

The muscles dilating the Chest.

Of these fortie foure, there are 22. which dilate the chest in drawing in the breath; that is, the *Subclavius*, the *Dentatus*, or *Serratus major* in the opinion of some, both the *Rhomboides*, or *Serrati possici*; the oblique ascendent of the lower belly, the eleaven *Intercostales*, and the sixe *Intercartilaginei externi*.

The muscles contracting the Chest. The *Subclavius* is the first of the muscles dilating the chest. *Serratus major*.

On the contrary, as many contract the breast in expiration; to wit, the *Sacrolumbus*, the oblique descendent, the Right and transverse of the lower belly, the inner Triangular, the sixe *Intercartilaginei*, and the eleaven inner *Intercostales*. Of these twentie two dilating the Chest, the first, from the site is called the *Subclavius*, for it descends obliquely from the inner and forepart of the *Clavicula* or Coller bone, into the gristle of the first ribbe, even to the *Sternum*, and dilates it. The second is the *Serratus major*, the greater Saw-muscle arising according to the opinion of some from the whole basis of the shoulder-blade on the inside, and it is transversely inserted into the nine upper ribbes, producing certaine toothed or saw-like processes running further to the bones of the rib, than to the spaces between them, or Intercostall muscles, whereupon it hath the name of the saw-muscle; yet some have referred this muscle to them of the shoulder-blade. The third descends from the three lower spines of the neck, and the first of the backe, by means of a membranous and most thinne ligament, into the three or foure upper ribbes, running further into their spaces or Intercostall muscles, than into the ribbes themselves, wherupon it is called *Serratus posterior*, & *superior*, that is, the hinder and upper saw-muscle. The fourth in like manner ascends by means of a membranous and thin ligament from the three upper spines of the loines, and the two last of the chest, or backe, into three or foure of the lower, or last of the bastard ribbes, sent forth further into them or their bones, than into the Intercostall muscles possessing the spaces betweene them, wherefore it is called *Serratus posterior* & *inferior*, the hinder and lower saw-muscle. Moreover these two last muscles have been called by a common name from their figure the *Rhomboides*, that is, the square muscles. The fift which we said was the ascendent of the *Epigrastrum*, hath already beene sufficiently described in his place. The eleaven *Intercostales externi*, or externall Intercostall muscles descend obliquely from the backe part of the lower side of the upper ribbe, into the forepart of the upper side of the ribbe lying next under it, after a quite contrary manner to the sixe *Intercartilaginei*, who having like originall and insertion amongst the gristles, as the Intercostall amongst the ribbes, descend obliquely from the forepart backwards. And thus much of the muscles dilating the Chest in inspiration.

Serratus posterior and *superior*.

The oblique ascendent of the lower belly.

The eleaven *Intercostales externi*.

6. *Intercartilaginei*.

The *Sacrolumbus*, the first of those which contract the chest.

But the first, of the other muscles, being as many in number, which contract the Chest in expiration, arising from the holy-bone, and the oblique processes of the loines, ascends (firmely and confusedly adhering with the *Musculus sacer*, or holy-muscle, which we shall describe hereafter) to the roots of the twelve ribbes, imparting in the ascent a small tendon to each of them, by which it drawes these ribbes towards the transverse processes; and by reason of its Originall it is called *Sacrolumbus*, that is, the Holy loine-muscle.

The

The second, third, and fourth, which we said were the oblique descendent, right, and transverse of the *Epigrastrum*, have been formerly described in their place.

But by the way you must note that these three muscles of the *Epigastrium* help expiration rather by accident, than of themselves, to wit, by driving backe the midriffe towards the lungs by the entrailles, which also they force upwards, by drawing the parts into which they are inserted towards their Originall. The fifth which we called the *Triangulus*, or Triangular, may be called the *Compressor* of the gristles, which proceeding from the inner sides of the *Sternon*, goes to all the gristles of the true ribbes; this is more apparent under the *Sternon* in beasts, than in men, though it be not very obscure in them neither. For the internall Intercoastall muscles, in my judgement, they arise from the lower sides of the upper ribbe, and descending obliquely from the fore part backwards, are inserted into the upper side of the ribbe next under it; so that they may follow the production of the fibres of the externall *Intercartilaginei*; as the fixe internall *Intercartilaginei* follow the site of the externall Intercoastall proceeding from behinde forwards; wherefore as well the Intercoastall, as the *Intercartilaginei*, every where intersect each other, after the similitude of the letter X. I know some have written that the internall muscles (whether intercoastall or *Intercartilaginei*) ascend from the upper sides of the lower ribbe forwards, or backwards.

But if this were true, it would follow that these muscles admitted their nerves in their taile and not in their head, seeing the nerve alwayes goes under the ribbe, and not above it.

The last muscle of the Chest, that is, the *Diaphragma* or Midriffe, is sufficiently described before; wherefore it remains wee describe the muscles of the Loines. These are fixe in number, on each side three, equall in thickness, strength and situation; one of these bends, and the other two extend the Loines; it is called by reason of the figure the *Triangulus*, or Triangular which bends the Loines, it ascends from a great part of the hinde side of the Hanch-bone into the transverse processes of the Loines, and the last of the Chest on the inside, for which cause it is made of fibres short, long, and indifferent, answering to the neareness or distance of the said processes. The first of the extenders is called the *Semispinatus*, because even to the middle of its body it takes the originall from the spines of the holy-bones and Loines; this with its oblique fibres ascends from all the said spines to the transverse processes as well of the Loines as Chest. The other is called *Sacer*, the Holy-muscle, because it takes its originall from the Holy-bone, or the sides thereof; it ascends with its oblique fibres to the spines of the Loines, and of the eleaven lower Rack-bones of the Chest.

CHAP. XIX.

Of the Muscles of the Shoulder-blade.

NOW we must describe the muscles of the extreme parts, and first of the Arme, taking our beginning from these of the Shoulder-blade. But first, that we may the better understand their description, we must observe the nature and condition of the shoulder-blade. Therefore the blade-bone on that part, which lies next unto the ribbs, is somewhat hollowed; wherefore on the other side it somewhat buncles out. It hath two ribbs, one above, another below: by the upper is ment nothing else than a border or right line, which looking towards the temples is extended from the exterior angle thereof under the collar bone, even to the Proesse *Coracoides* which this ribbe produces in the end thereof: By the lower, the underside which lies towards the lower belly and the short ribbs.

Besides in this shoulder-blade we observe the *basis*, head and spine. By the *basis* we understand the broader part of the shoulder-blade, which looks towards the

The descrip-
tion of the
blade-bone,
or shoulder-
blade,

The basis of
the blade.

The head of
the shoulder-
blade.

backe-bone. By the head we understand the narrower part thereof, in which it receives the head of the Arme in a cavity, indifferently hollow, which it produces both by it selfe, as also by certaine gristles, which there fastened encompassse that cavity. This kinde of cavity is called Glene.

The spine of
the blade.
The proecess
Acromion and
Coracoides.

This receives and contains the bone of the arme, by a certaine strong ligament encompassing & strengthening the joynt, which kind of ligament is common to all other joints; this ligament arises from the bottome of the cavity of the shoulder-blade, and circularly encompassse the whole joynt, fastening it selfe to the head of the arme; there are also other ligaments besides this, which encompassse & strengthen this articulation. By the spine is ment a proecess, which rising by little and little upon the gibbous part of the blade, from the *basis* thereof where it was low and deprest, becomes higher untill it ends in the *Acromion*, or upper part thereof. Nature hath made two productions in this bone (that is to say, the *Acromion* from the spine, and the *Coracoides* from the upper side) for the strengthening of the articulation of the arme and shoulder-blade, that is, lest the arme should be easily strained upward or forwards; besides, it is fastened to the clavicle, by the proecess *Acromion*.

The muscles
of the shoul-
der-blade.

The muscles which move the shoulder-blade are sixe in number, of which foure are proper, and two common. The first of the foure proper seated in the forepart, ascends from the bones of five or sixe of the upper ribbs, to the *Coracoides*, which it drawes forwards, and is called *Serratus minor*, that is, the Lesser saw-muscle; which that you may plainly shew, it is fit you pull the pectorall muscle from the collar-bone, almost to the middle of the *Sternon*. The other first opposite against it, is placed on the fore side, and drawes its originall from the three lower spines of the necke, and the three upper of the Chest, from whence it extends it selfe, and ends into all the gristly *basis* of the shoulder-blade, drawing it backwards; it is called the *Rhomboides*. The third from its action, is called the *Levator*, or the heaver, or lifter up, seated in the upper part, it descends from the transverse proecesses of the foure first *Vertebra* of the necke into the upper angle and spine of the blade. The fourth called *Trapezius*, or the Table-muscle, is seated in the backe part, and is membranous at the originall, but presently becoms fleshy: it arises from almost all the backe-part of the head, from all the spines of the necke, and the eight upper *Vertebra* of the chest, and then is inserted by his nervous part, almost into the whole *basis* of the blade, extending it selfe above the muscles thereof, even to the midst of its spine, where being fleshy it is inserted even to the *Acromion*, the upper part of the clavicle, and in some sort to the upper ribbe. This muscle hath a threefold action, by reason of its triple originall. The first is to draw the shoulder-blade towards its originall, that is, to the nowle, and spine of the necke; the other is to draw it towards the backe, because of the contraction of the middle or transverse fibers which leade it directly thither; and the other is to draw it downwards by reason of the originall it hath from the fifth, sixth, seventh, and eight spine of the *Vertebra* of the Chest.

*Serratus mi-
nor*.

Rhomboides.
Levator.

Trapezius.

But we must note that these diverse actions are not performed by this muscle, by the assistance of one onely nerve, but by more, which come into it by the spinall marrow, by the holes of the *Vertebra*, as well of the necke as the chest, from whence it takes the originall. For the two other which are the common muscles of the blade, and arme, or shoulder; we will describe them with the muscles of the shoulder or arme: for one of these which is called the *Latissimus*, that is, the broadest, ascends from the holy-bone to the shoulder-blade and arme.

Latissimus.

Pectoralis.

The other named the *Pectoralis* comes from the *Sternon* and collar-bone to the shoulder-blade and arme.

CHAP. XX.

The Description of the Hand taken in Generall.

NOW it befits us to to describe in order the muscles of the arme; but first we must know, what it is that we call the arme. But seeing that cannot fitly be understood, unlesse 1. we know what the hand is, seeing that the arme is a part of the hand; therefore first we must define what a hand is, and

and then divide it into its parts. Therefore the hand is taken two manner of wayes, that is, generally and specially.

The hand generally taken, signifies all that which is contained from the joyning of the arme to the shoulder-blade, even to the ends of the fingers. But in particular it signifies onely that which is comprehended from the furthest bones of the cubit, or the beginning of the wrest, to the very fingers ends.

What is meant
by the hand
in generall.

Therefore the hand in generall is an instrument of instruments made for to take up and hold any thing. It is composed of three great parts, that is, of the Arme, Cubite, and Hand, vulgarly, and properly so called; but the hand taken thus in particular is againe divided in three other parts, the *Carpus* or *Brachiale*, the *Wrest*, the *Metacarpium*, or *Postbrachiale*, the after wrest, and the fingers; all these parts (seeing each of them are not only organicall parts, but also parts of organicall parts) are composed of all, or certainly of the most of the simular parts, that is, of both the skinner, the fleshy pannicle, the fat vaines, arteries, nerves, muscles or flesh, coats both common and proper, bones, gristles and ligaments, all which we will describe in their order.

But first I thinke good to admonish you of the differences of the hand taken from the site thereof; and these differences are fixe in number, the fore, the hinde, the internall, the externall, the upper and lower side or part thereof.

The differences
of the
hand from the
site thereof.

By the fore we meane that part which looks directly from the thumbe to the shoulder: by the hinde, we understand the part opposite to it, which from the little finger looks towards the basis of the shoulder-blade. By the inside we signifie that part which lies next to the sides of the body, when the hand retaines its naturall site; by the outside, the part opposite to it. The upper and lower side you may know by the very naming thereof.

The hand properly so called is divided into five fingers, that so it may hold and take up bodies of all figures, as round, triangular, square and the like, and gather up the least bodies with the fingers ends, as needles, pins, and such like.

Why the hand
is divided into
so many finger
s.

Nature hath bestowed two hands upon us, that so they may helpe each other, each moving to each side. But for the taking up and holding of small bodies it was fit, that the fingers of their owne nature soft, should be armed with nailes, that consisting of soft flesh and an hard naile, they might serve for all actions; for the naile is a stay to the soft flesh, which otherwise would turne away in meeting with an hard body; the use of the nailes is to scratch, shave, and pull off the skinner, to rend, pinch, and plucke asunder small bodies. They have not bony hardnesse, that so they might not breake, but bend.

Why the
nailes are ad-
ded to the soft
flesh of the
fingers.

Yet other creatures have hard nailes, to serve them in stead of weapons. Their figure is round, because such a figure is lesse obnoxious to externall injuries; and by reason they are subject to wearing, they grow continually.

Why the nailes
grow continu-
ally.

Nature hath placed flesh on the inner and side part of the fingers, so to presse more straitly, the things they once take hold of, so that by holding them close together, we can hold water that it may not runne out. The length of the fingers is unequal, that when they are opened and stretched forth, they make as it were a circular figure; for so it comes to passe, that the hand can hold all bodies, but especially round.

It remaines that we prosecute the distribution of the veines, arteries, and sinewes, which runne over all the parts of the hand taken in generall and particular, whereby wee may more commodiously hereafter handle all the proper parts thereof.

CHAP. XXI.

*The Distribution of the Subclavian veine, and first
of the Cephalicæ, or Humeraria.*The Cephalicæ
veine.

Two large veines descend from the Subclavian, the one from the lower side, the other from the higher. Yet sometimes, and most usually, both these proceede from the same common orifice, as in men of a low stature in the arme. The one of these is called the *Axillaris*, the other the *Humeraria*, or *Cephalicæ*; therefore this Cephalicæ passing forth of the Subclavian runnes superficially along the foreside betweene the muscle *Deltoides*, and the Tendon of the pectorall muscle, and descends in the midst betweene the common coate of the muscles and the fleshy pannicle, even to the bending of the cubite, where in leane bodies it is plainly to be scene, whereas in fat bodies it is hardly to be perceived, being as it were buried in abundance of fat. This veine having in its descent, sent forth some small branches, both to the skinn, as also to certaine muscles over which it runs, is devided into two, a little above the outward protuberation of the arme. One of the branches into which it is devided descending obliquely to the fore part of the cubite, a little below the bending of the cubite, it meets, and is united with the like branch in the same place, as shall be showne hereafter.

The median
veine.

How by opening the median veine, you may draw more or lesse blood from the head or liver.

That which arises from this concurrence, is called the median veine, because it arises from two branches, and is seated betweene them. They usually open this median veine in the diseases of the head and liver, which require Phlebotomy; but if it shall not be sufficiently manifest, when you judge it must be opened, for a generall evacuation of the whole body; you may cut one of these branches, by whose concurrence it is made, which you shall think the fitter; and because each branch drawes from the next parts, according to the straightnesse of the fibers, rather than from the opposite side; if you would evacuate the head, and liver equally, by opening either of these branches; it is convenient that opening that branch (for example) which comes from the Cephalicæ, you presently lay your thumbe upon it, untill you suppose, you have drawne a just quantity of blood from the liver, by the *Basilica*, or liver veine; which done, you may take off your thumbe, and suffer the blood to follow freely, by the open branch of the Cephalicæ, untill you have drawne as much blood as you shall judge requisite; otherwise you will draw it but from one part, to wit, the head. So you shall evacuate it onely from the liver, if you open the branch which comes from the *Basilica*, and concurs to the generation of the median.

Moreover, when there is neede to open the *Basilica*, and it shall be no where conspicuous, the Cephalicæ or median being easie to be discerned at the same time, you may in stead thereof open the median, or if it be not to be found, the Cephalicæ, pressing but the trunk thereof with your thumbe, as we said before, lest the head should be evacuated in stead of the liver. You may doe the same in the *Basilica*, if when there shall be necessitie to open the Cephalicæ, it shall not appeare. Most of those which at this day open a veine, in stead of the median, open that branch of the *Basilica* which ascends, together with the Cephalicæ to make the median. But you must understand that the median descends betweene the two bones of the cubit, even to the end thereof, and then devided into many branches, it is at length spent on the backe of the hand behinde the thumbe, the fore and middle fingers, or the afterwrest. Sometimes it runs backe into the following branch, and then at the wrest it departs from it, to be bestowed upon the forementioned parts. The other branch of the Cephalicæ, which we may call the fore and outward Cephalicæ, descending directly downe to the midst of the wand, thence wanders overthwart into the hinde part of the arme, where encreased with a branch from the *Basilica*, it is distributed over all the backe of the hand, which with the median it nourishes. But the branches of these veines doe so run through the forenamed parts, that by the way, they yeeld them necessary provision.

CHAP. XXII.

The Description of the Axillary veine.

 He Axillary arising at the insertion of the pectorall muscle, or a little higher, after it hath produced the two *Thoracica* it is divided under the tendon of that muscle into two faire branches, that is to say, into the inner deepe Axillary, and the skinne or outward axillary. The deepe or inner having still for his companion in his descent, the axillary artery, and the nerves of the third conjugation, after it hath produced the small externall musculous of the arme, it goes into the bending of the elbow, where running somewhat deepe with the artery and nerve into the muscles of the cubite, it is divided into three other branches, of which one descending with the wand, slides under the ring, into the inner side of the hand, and hath bestowed two small branches on the thumb, two others on the fore, and one upon the middle finger, so that all of them ascend by the sides of these fingers, the other descending with the artery, as the former alongst the cubite, sends branches to the rest of the fingers, like as the former. The third goes on the fore side betweene the two bones even to the wrist, and the square muscle.

The axillary
is divided into
to

The deepe
axillary, and
outward axil-
lary.

But you must note that the veines of which we now treat, doe not onely make these divisions mentioned by us, but infinite others besides, as well in the parts which they goe to, as also in the inner muscles of the hand which they nourish.

And thus much of the internall and deepe axillary veine. For the externall or skin Axillary (which first appeares under the skinne, especially in leane bodies, a little above the inward production of the arme) it is divided in that place into two branches, the one whereof descending to the bending of the arme meets, and is united with the Cephalike branch, sooner or later, that so it may produce the median, as we formerly mentioned.

The other branch (having sent forth many shoots of a different length and thickeffe, as well into the skinne, as into the other neighbouring parts, descending alongst the lower side of the bone of the cubite, properly so called, is at length spent upon the fore and outward Cephalicke branch, which we said descended alongst the wand; and thus united, they runne over all the hand, where in the right hand, betweene the middle and fore finger, they make the *Salvatella*; but in the left, in the same place, they produce the *Splenitica*.

The *Salvatella*
and *Splenitica*

But alwayes remember, (if in dissection you finde any thing otherwise than we have delivered it) that the distribution of the vessels is so various (especially in the hands) that there can no certaine rule be delivered thereof.

CHAP. XXIII.

The Distribution of the Axillary Artery.

 He Axillary artery from the first originall, which is presently after the two *Thoracica*, descending betweene the muscle called *Biceps*, or the two headed muscle, and the *Brachieus*, with the deepe axillary veine, distributes a large branch amongst the outward muscles of the arme, which extend the cubite, and is spent in the externall muscles of the same, which arise without, from the productions of the arme.

And

An Axiom
call Axioms.

And this is called the *Ramus Musculus*, or Musculous branch, as also the veine that accompanyes this Arterye. Then this Arterye when it comes to the bending of the cubite, thrusting it selfe into the muscles bending the fingers, communicates certaine branches to the parts pertaining to the dearticulation of the cubit with the shoulder, and other parts there situate, as it did in the upper parts, by which it descended hither. Verily it may be a generall rule; that every vessell sends or bestowes certaine portions thereof by the way to all the parts by which it passes. But if you should aske, why I have not prosecuted these productions, I would answer, I never intended, to handle other than large and faire branches of vessels, by rash incision of which, there may happen danger of death or a disease. For it would be both an infinit and needles busines to handle all the small divarications of the veines, arteryes and nerves. Therefore this Artery funke into these muscles, when it comes almost to the midst of the Cubit, presently or a little after it is divided into two large branches, the one of which alongst the wand, & the other alongst the Cubite is carryed into the hand on the inside under the Ring. For both these branches are distributed and spent upon the hand after the same manner as the branches of the internall Axillary veine, that is, having sent by the way some little shoots into the parts by which they passe, at the length the branch which descends by the Wand of the remainder therof, bestowes two sprigs upon the Thumbe, on each side one, & two in like manner on the fore finger, and one on the middle; the other which runs alongst the Ell, performs the like office to the litle and the middle or ring finger, as you may see by dissection.

CHAP. XXIII.

Of the Nerves of the Necke, Backe, and Arme.

The 7 paire of
nerves of the
necke.

The first
paire.

Now we should handle the sinewes of the Arme, but because these proceed from the Nerves of the Necke and Backe, I thinke it fit therefore to speake something of them in the first place.

Therefore from the Necke there proceed seven paire of Nerves, the first of which proceeds from the nowle bone, and the first *Vertebra* of the necke; as also the first paire of the Backe from the last *Vertebra* of the Necke and the first of the Chest. But all these Nerves are divided into two or more branches of the first paire (that is to say, on each side) goe, the one to the small right muscle, ascending from the first racke-bone of the necke to the nowle bone, the other to the long muscle on the foreside of the necke.

The second
paire.

The branches of the second paire are distributed, some with a portion which they receive from the third paire over all the skin of the head; the two others go as well to the muscles, which are from the second *Vertebra* to the backe part of the head, and from the same to the first *Vertebra*, as also to the long muscle before mentioned.

The third
paire.

One of the third paire of Sinewes is communicated to the head, as we said before, but others to the Muscles which extend, or erect the head and the Necke; there is also one of these distributed into the neighbouring side muscle and part of the long.

The fourth
paire.

The nerves of the fourth paire go, one to the muscles aswel of the neck as the head, & to the broad muscle; the other after it hath sent some portiō therof into the long muscle & the side muscles of the necke, it descends with a portion of the fift and sixt paire

The fift paire.

to the Midriffe. One of the branches of the fift paire is bestowed on the hinde muscles of the necke and head, the other upon the longe muscle and Midriffe; the third is communicated to the *Levatores*, or Heaving muscles of the Arme and shoulder.

The sixt paire

One of the Nerves of the sixt paire goes to the hinde muscles of the Necke and head, another to the Midriffe, the third with a portion of the seventh paire of the necke, and of the first and second of the Chest goe to the Armes and heaving muscles of the shoulder-blade.

The seventh
paire.

One of the branches of the seventh paire runs to the broad muscle and to the neighbouring muscles both of the necke and head; another encreased with a portion of the fift and sixt paire of the necke, and a third joyned to the second and third paire of

of

of the Chest descending into the Arme goe to the hand.

But you must note that the Muscles which take their originall from many *Vertebrae*, whether from above downwards, or from below upwards, admit Nerves not onely from the *Vertebrae*, from whence they take their originall, but also from them which they come neere in their descent, or ascent.

There passe twelue conjugations of Nerves from the Rack-bones of the Chest.

The 12. paire
of Nerves of
the Chest.
The first paire

The first entring forth from betweene the last Racke-bone of the necke and the first of the Chest, is divided (that is, on each side, each Nerve from his side) into two or more portions, as also all the rest. Therefore the branches of this first conjugation goe some of them to the Armes, as we said before, others to the muscles as well these of the Chest, as others arising there, or running that way.

The branches of the second conjugation are distributed to the same parts, that these of the first were.

The second
paire.

But the branches of all the other conjugations even to the twelfth, are communicated, some to the intercostall muscles running within under the true ribs even to the *Sternum*, and under the bastard ribs even to the right and long muscles; and the Costall Nerves of the sixt conjugation are augmented by meeting these intercostall branches by the way as they descend by the roots of the Ribs. Other particles of the said Nerves are communicated to the muscles as well of the Chest, as spine, as the same Muscles passe forth, or runne alongst by the *Vertebrae*, from whence these nerves have either their originall, or passage forth.

The other
paires.

Having thus therefore shewed the originall of the Sinewes of the Arme, it remains that we shew their number and distribution.

The Nerves
which are
carried to the
Armes.

Their number is five or sixe; proceeding from the fifth, sixth, and seventh *Vertebrae* of the necke, and the first and second of the Chest. The first of which not mixed with any other from the fifth *Vertebra* of the necke, goes to the Muscle *Deltoides* and the skin which covers it.

The other 4 or 5 when they have mutually embraced each other, not onely from their first originall but even to the shoulder, where they free themselves from this convolution, are distributed after the following manner.

The first and second descending to the Muscle mentioned a litle before, and thence sometimes even to the hand, is by the way communicated to the Muscle *Biceps*, and then under the said Muscle it meets and is joyned with the third Nerve. Thirdly it is communicated with the Longest muscle of the Cubite, in the bending whereof it is divided into two branches descending alongst the two bones of the Cubit, untill at last borne up by the fleshy pannicle it is spent upon the skin and inner side of the hand.

The third lower than this, is first united with the second, under the Muscle *Biceps*, then straight way separated from it, it sends a portion thereof to the Arme which lyes under it, and to the skin thereof; lastly at the bending of the Cubit on the fore side, it is mingled with the fift paire.

The fourth, the largest of all the rest, comming downe below the third branch under the *Biceps* with the internall Axillary veine and Artery, is turned towards the outward and backe part of the Arme, there to communicate it selfe to the Muscles extending the Cubit, and also to the inner skin of the Arme and the exterior of the Cubit; the remainder of this branch when in its descent it hath arrived at the joynt of the Cubit, below the bending thereof it is divided into two branches, the one wherof descending alongst the Cubit is spent on the outside of the Wrist; the other associating the Wand is on the outside in like manner in two branches bestowed upon the Thumbe, and in as many upon the fore finger, and by a fift upon the middle finger though more obscurely.

The fift branch being also lower than the rest, sliding between the muscles bending and extending the Cubite, when it comes behinde the inner protuberation of the Cubite (in which place we said before the third branch meets with this) it is communicated to the internall muscles of the same, and then divided into three portions one of which on the outside alongst the middle of the Cubite goes in two sprigs to the litle finger, & so many to the middle finger, and one to the Ring finger, the other

two

two, the one without and the other within the Ring, goe to the hand, where after each of them hath bestowed what was requisite on the muscles of the hand, they are wasted into other five small portions, of which these which are from that portion which descends without the Ring, send two sprigs to the litle, two to the fore and one to the middle finger; but these which come from that which passes under the Ring, by such a distribution communicates it selfe to other fingers, as two sprigs to the thumbe, two to the fore and one to the middle finger. The sixt the lowest and last runs betweene the skin and fleshy Pannicle, by the inner protuberation of the Arme, and then is spent upon the skin of the Cubit.

CHAP. XXV.

The description of the bone of the Arme, and the Muscles which move it.

The great
neffe and
figure.
The Appendix
of the Arme.
The processe
of the Arme.

BEcause we cannot perfectly demonstrate the originall of the muscles of the Arme, (especially of the two Arme muscles) not knowing the description of this bone; first therefore we will describe it, then returne to the originall of the muscles arising from thence. The bone of the arme is the greatest of all the bones in the body, except the Thigh-bone; it is round, hollow and filled with marrow, with a great Appendix or head on the top thereof, having an indifferant necke, to which it is knit by *Symphysis*, for appendices are no otherwise united to their bones. In the lower part thereof it hath two processees, or protuberations, one on the fore side, another on the hinde, betweene which swellings there is a cavity like to halfe the compasse of a wheele, about which the Cubit is moved. The extremities of this cavity ends in two holes, of which one is the more externall, the other more internall: these cavities receive the heads of the Cubite, that is, the fore, or internall receives the fore processe when the arme is bended inwards, but the externall or hinder the exterior, as it is extended.

For the head of the arme it hath a double connexion, the one with its owne necke by *Symphysis*, that is, a naturall union of the bones without any motion; the other with the lightly ingraven cavity of the shoulder-blade, which we call *Glene*, by that kinde of Dearticulation which is called *Arthrodia*; this connexion is made firme and stable by the muscles descending into the arme from the shoulder-blade, as also by the proper Ligaments descending from the circle and brow of the cavity of the *Acromion* and *Coracoides* to this head of the arme; this same head of the arme is, as it were more cleft and open on the inner side, than on the fore side, that so it may give way to one of the Ligaments comming from the shoulder-blade to the muscle *Biceps*. For as much as belongs to the lower end of the bone of the arme (which we said hath two processees) we may say that it is fastened to the bones of the Cubit by two sorts of articulation, that is, by *Ginglymos* with the Ell or proper bone of the Cubit, and by *Arthrodia* with the *Radius* or Wand, which in a lightly engraven cavity receives the fore processe of the arme, and is turned about it for the motion of the hand. The hinder processe is chiefly added for the safety and preservation of the veins, arteries and nerves.

The figure of
the Arme.

These things thus showne, it is worth our labour to know the figure of the arme it selfe, as it lyes betweene the forementioned appendices and processees, that in the case of a fracture, we may know how conveniently to restore it; therefore first we must understand, that this bone is somewhat bended and hollowed on the inside under the cleft of the head thereof, but bunching out on the out and fore side.

The 8 muscles
thereof.

Wherefore seeing it must be moveable forwards and backwards, upwards and downewards, nature for the performance of so many motions hath furnished it with eight muscles, which are sixe proper and two common with the shoulder-blade. Of which number two move it forwards, two backwards, two upwards and downewards. Which must not be understood so, as that these two Muscles should move it directly forwards inclining either upwards, nor downewards; and the other two should move it

Table 24. sheweth the Braine together with the After-braine, the spinall marrow and the Nerves of the whole body.

- A, That part of the braine that is at the nosethrills.
- B, That part which is at the side of the ventricles.
- C, The back part of the braine.
- D, The *Cerebellum* or After-braine.
- E, The Mamillary proceſſe in the right ſide.
- F, The originall of the opticke nerve.
- G, Their conjunctions.
- H, The coate into which the opticke nerve is extended.
- I, The ſecond paire of the ſinewes of the braine.
- K, The leſſer roote of the third conjugation.
- L, The thicke roote of the ſame conjugation according to the common opinion.
- M, The fourth conjugatiō of the ſinews
- N, The leſſer roote of the fiſt paire.
- O, The bigger roote of the ſame paire.
- P, The ſmall membrane of the eare which they call the *Tympany*.
- Q, The lower branch of the bigger roote of the fiſt conjugation.
- S, The ſixt paire of ſinewes.
- T, The ſeventh paire.
- V, The beginning of the ſpinall marrow out of the middle of the baſis of the braine.
- X, The right ſinew of the midriff cut off.
- r, A branch from the fiſt paire creeping to the top of the ſhoulder.

- Z, The fiſt nerve of the arme from whence there goeth a branch to the ſkin.
- A, The ſecond nerve of the arme, and a branch there from into the fiſt muſcle of the Cubite.
- B, The third nerve of the arme and a branch going to the ſkin on the outſide.
- C, A branch from the 3^d nerve to the 2^d muſcle of the Cubite.
- D, The congreſſe or meeting of the ſecond nerve with the third.
- E, A ſmall branch from the 3^d nerve to the 2^d muſcle of the *Radius*.
- F, The diſtribution of the ſecond nerve into two branches.
- G, The leſſer branch of this diviſion lengthened out to the ſkin as far as the thumb.
- a, The place of the ſpinall marrow where it iſſueth out of the braine. 1, 2, 3, &c.
- Thirty paires of nerves ariſing from the ſpinall marrow are here noted by their Char. that is to ſay, 7. of the necke, 12, of the Cheſt, 5. of the loynes and 6, of the holy-bone.
- b, The thicker branch of the 2^d nerve divided into 2, parts.
- c, Branches of the 3^d nerve ſprinkled here and there.
- d, Nerves from the third paire to the thumb, the forefinger and the middle finger.
- ee, The 4th nerve of the arme. f, The paſſage hereof through the inſide of the ſhoulder.
- g, A tripartition of this branch where it toucheth the Cubit. bb, A branch diſtributed from

from the 4. nerve to the outward skin of the Cubite. *i*, the upper branch of the division of the 4. nerve. *kk*, A branch of *i*, reaching to the outside of the hand. *ll*, the lower branch of the division of the 4. nerve passing through the backside of the Cubite. *m*, the 5. nerve of the arme. *n*, Branches of this nerve dispersed here and there. *oo*, A branch of the 5. nerve reaching to the inside of the hand and the fingers. *p*, A surcle of the branch *o*, derived to the outside of the hand and the fingers. *qq*, the 6. nerve of the arme and the course thereof under the skin. *rr*, the intercostall nerves there cut off where they are together with the ribs reflected forward. *ss*, branches on each side running backward. *tt*, Nerves attaining unto the Chest. *uu*, the commixtion of the nerves *rr*, with the descending branch of the 6. conjugation of the braine. *xx*, Nerves from the loynes led unto this place. *y*, A branch going to the testicle here cut off. *z*, A nerve reaching to the 1. muscle of the thigh. *a*, the 1. nerve of the leg. *ab*, A surcle of the former nerve derived to the skin at *a*, and inserted into the muscles at *b*. *c*, the 2. nerve of the leg. *dd*, A nerve from the former, allowed unto the skin as low as to the foot, and passing along the inside of the leg. *e*, a branch of the 2. nerve running unto the muscles. *f*, the 3. nerve of the leg. *g*, a surcle thereof unto the skin. *h*, another surcle unto the muscles. *i*, the 4. nerve of the leg. *xx*, the *anterior* propagations of the nerves proceeding from the holy bone. *l*, the end of the spinall marrow. *m*, a branch from the 4. nerve inserted into the muscles arising from the *Coxendix* or hip bone. *n*, another branch going to the skin of the thigh on the backside. *o*, a propagation derived to the 4. muscle of the leg and to the skin of the knee. *oo*, nerves attaining to the heads of the muscles of the foote. *p*, the division of the 4. crurall nerve into two trunks. *q*, a branch from the trunk *p*, dispersed into the outward skin of the leg. *r*, a surcle of the trunk *p*, derived to the muscles. *s*, another surcle to the skin of the leg on the foreside. *t*, a branch of the trunk *p*, to the skin of the inside of the leg and of the foot. *x*, a surcle of the trunk *p*, to the hindmost skin of the leg. *y*, a branch of the whole trunk *p*, led along to the forward part of the leg and the foot. *z*, the descent of the trunk *p*, into the foot.

it so upwards, as it should incline neither foreward, nor backwards; but thus, that it cannot be moved neither to this nor that part unlesse by the helpe and proper action of this, or that muscle. Thus therefore if the Pectorall with his associate performe their duty or action, the arme is alwayes moved forwards, as it is lifted up by the action of the *Deltoides* and his companion, and so of the rest.

The originall
and insertion
of the pecto-
rall muscle.

But to come to the originall and insertion of these muscles; the one of these two which move the arme forwards called by reason of his originall, the Pectorall, arising from more than halfe of the Collar bone, and almost all the *Sternum* and the 6, 7. and 8, Rib, goes up and fastens it selfe to the *Coracoides*, by a membrane or a membranous tendon sufficiently strong (for which cause it is said to be common to the shoulder & arme) and it goes into the arme betweene the muscles *Deltoides* and *Biceps* with a strong tendon composed of fibers crossing each other, of which some descend from the Collar-bone and the upper part of the *Sternum*, others ascend from the lower originall hereof, that is, from the 6, 7, and 8, Ribs: and although the action of this muscle be diverse, by reason of the diversity of its fibers arising from divers places, yet alwayes it drawes the arme forwards, whether it be moved upwards, downwards, or to the Breast; the other which is his companion descends from the whole lip or brow of the simous or hollow part of the Blade, which it fills in the forepart of the arme neere the head thereof. For the two *Levatores*, or the Lifters up of the arme, the first named *Deltoides* descends from almost halfe the Clavicle, the proesse *Acromion* and all the spine of the shoulder-blade into the foreside of the arme the bredth of foure fingers below the joynt. It hath divers actions according to the diversity of the fibers, as also every muscle hath; yet howsoever it is contracted, whether by the fibers from the clavicle alone, or by the spinall alone, or by both at once, it alwayes lifts and heaves the arme upwards. The other which is his associate descends from the gibbous part of the Shoulder-blade contained betweene the upper rib therof & the spine between the proesses *Acromion* and *Coracoides*, to the neck of the arme; and this we will call the *Epomis* or *Scapularis*, that is, the shoulder Muscle. But the first and larger of the two muscles,

The *Deltoides*

The *Epomis*,
or *Scapularis*.

muscles, which draw the arme backwards, arises from the greatest part of the utter lip of the gibbous part of the shoulder-blade, which is under the spine thereof, & lying upon the blade it self, it goes into the hind part of the arme above the neck thereof. The other which is contiguous to it & his partner in working, but lesser, passes from the upper and exteriour part of the lower rib of the shoulder-blade, and thence as it were in some sort extending it self upon the gibbous part thereof neere unto that rib, it goes into the arme. This muscle seemes to be the same with the former, being fleshy without even above the top of the shoulder. One & the lesser of these two which draw downwards, enters out from the streight line of the lower Rib of the blade, & goes into the lower part of the arme about the neck thereof. The other called the *Latissimus* or broadest, ascends from the spines of the holy-bone, of the Loynes, & often also from the nine lower of the Chest, by the lower corner of the shoulder-blade into which it is inserted by a membranous tendon, as also it is into the inner part of the arme neere unto the necke by another strong tendon; wherupon this muscle is called a common muscle of the shoulder and arme. But when this muscle happens to be wounded, the arme cannot easily be stretched forth, or lifted up.

CHAP. XXVI.

The Description of the bones of the Cubit and the muscles moving them:

After these muscles, follow those which bend & extend the cubit, but because their insertion cannot be fitly demonstrated, unless the bones of the cubit be first described; therefore first of all we will delineate the bones themselves. But verily lest this doubtful word cubit should cause obscurity, first we must note, that it hath a threefold significatiō; for oftentimes it is used for althat part of the hand which lies between the arme & wrest, oft times for the lower bone of this part, sometimes for the upper part of this bone which is turned within the Orbe or Cavity of the arme (no otherwise than a cord in the wheele of a Pulley) and this is called the *Olecranon*. Here truly we use this word Cubit in the first signification. Wherefore we say the cubite is composed of two bones, the one of which we call the *Radius* or Wand, or the lesser *Osse* of the Arme; the other we properly call the Cubit or Ell. These two bones sticke together at their ends being firmly bound together by strong Ligaments; but the middle parts of them are a pretty way distant from each other, & chiefly towards their lower ends, for the better scituation and passage of the muscles and vessells from the inner side, to the exteriour, as shall be shewed in fit place. The wand hath two *Epiphyses* or Appendices, the one at the upper end, the other at the lower. The upper is round & hollowed on the surface like a balon, it receives the fore proesse of the bone of the arme, bound to the same by strong ligaments, descending as wel from that proesse of the arme, as the *Olecranon* into the circumjacent parts of this appendix of the Wand. This connexion is made for this use, that we may turne our hand upwards and downwards by the Cubit turned and twined about this proesse. But the lower appendix of this wand is hollowed on the inside that so it might more commodiously receive the bones of the wrest, but gibbous without, that it might be safer; now this wand is softer and thicker at the lower end, but lesser and harder above, where on the inside it hath a swelling out, wherby to receive the muscle *Biceps*, besides on the outside of the middle thereof it is somewhat gibbous and round, so to become more safe from the injuries of externall bodies, but it is hollowed, or bended on the inside for the better taking, or holding any thing in the hand. But that side which ly'es next to the Ell is flatted for the fitter originall and seat of the muscles; lastly it is seated upon the bone of the Cubit, or Ell, just against the thumb. But the Ell, or bone of the cubit properly & particularly so called, hath in like maner two appendices, the one above, the other beneath. The upper which also is the greater, is fitted to the Orbe of the arme, in which it goes to & again for the extensio & bending of the arme, no otherwise than a rope runs in a pulley but that it turnes not absolutly & perfectly round, which is caused by the two proesses of unequal bignesse, the which are therefore staid in the holes or cavities of the bone of the

the arme, the greater proceſſe which we called *Olecranon* is letted by the exterior hole that ſo the extension of the arme can be no further, but the leſſer proceſſe by the inner hole makes the bending therof the leſſe perfect. The Compoſure of theſe bones is by *Ginglymos*, & it is ſtrengthened not onely by common Ligaments comming from the muſcles, which move the bones themſelves, but alſo by proper Ligaments deſcending from the proceſſes of the arme & the lips of the holes and cavities ſtanding about the Appendix of the Cubit. The other lower and leſſer appendix is in ſome ſort hollow on the inſide for the ſitter receiving the bones of the wreſt, but the outſide is round & ends in a point, whence it is called by the Greeks *Styloides*. But now this Ell (contrary in this to the wand) is thicker towards the arme, but ſlenderer towards the wreſt. And beſides in the thicker part therof it is hollowed or bended towards the inſide, & in the ſame place is gibbous or bunching forth on the out ſide; but it is round & ſtraight, unleſſe on that ſide which lyes next the wand, for the reſt, it is hollow & full of marrow like the wand. The ſire of the *Radius* or wand is oblique, but that of the Cubit or Ell is right, that the arme might be the better & more eaſily moved; becauſe the motion by which the arme is extended & bended is according to a right line, but that by which the inſide of the hand is turned upwards & downwards, is performed obliquely & circularly. Wherefore it was expedient that the wand ſhould be oblique, & the cubit ſtreight for the cubit-bone is appointed for to extend & bend the arme; but the wand to performe the wheeling & turning about therof, & this is the cauſe that it was fitting ther ſhould be a different connexion of theſe bones with the arme. Theſe things were fitting to be ſpoken concerning the nature of theſe bones, that in the cure of fractures we may worke the more ſafely & happily, taking indication from that which is agreeable to nature: wherefore now it remains that we come to the deſcription of the muſcles which are ſeated in the arme, the cubit-bone, or Ell. Theſe are 4, in number, two extending it, & two bending it. The firſt of the Benders is called *Biceps*, by reaſon of its two heads; the one wherof deſcends from the *Coracoides*, that other from the lip of the cavity of the ſhoulder-blade by the fiſſure or cleft of the head of the bone of the arme. Theſe two heads under the necke of this arme becoming fleſhy, are firmly united at the belly & midſt of the arme, & thus united are at length implanted by a ſtrong tendon to the inner protuberation of the wand. The other is called the *Brachialis*, by reaſon of the ſtraite coherence therof with the bone of the arme; this faſtened under the *Biceps* deſcends obliquely on the backe and upper part of the bone of the arme into the top of the wand and the inner ſide of the Ell. But the firſt of the extenders is called the *longus* or Long muſcle, this deſcends from the lower Rib of the ſhoulder, and cleaving to the bone of the Arme goes thither (faſtened and as it were alwayes moſt ſtraightly joyned with his fellow muſcle, ſpecially nere the Cubite) where you ſhall preſently heare. The other termed the *Brevis* or ſhort Muſcle, being the companion of the long, deſcends on the hinde part of the necke of the bone of the Arme, as it were growing to and lying under the former long muſcle, ſo that making one common broad Tendon outwardly fleſhy, inwardly nervous, they are inſerted into the *Olecranon*, ſo by mutuall aſſiſtance to extend the Cubite.

CHAP. XXVII.

The Deſcription of the Bones of the Wreſt, Afterwreſt and fingers.

What the
Hand properly
ſo called is.

E ſaid before that the Hand taken more particularly and properly, is divided into the Wreſt, afterwreſt & fingers, & that the hand in this ſignification is bounded by the ends of the bones of the cubit and fingers. All the parts of the wreſt, which it hath comon with the afterwreſt, have bin already alſo plentifully explained, this only remains to be noted, that the ſkin aſwell of the hands as of the feete, is of a middle nature betweene pure fleſh and pure ſkin, no otherwiſe than that which covers the forehead, but that this which covers the palmes of the hands & ſoles of the feet is unmoveable; But it is moſt thicke, eſpecially on the feete, leſt it ſhould be eaſily offended by continuall going. Beſides the common parts, the wreſt is compoſed of eight ſmall bones mutually knit together in

a certaine order, and by *Diarthrosis* with the two bones of the Cubite, but mutually and amongst themselves by *Synarthrosis*, by interposition of Gristles and Ligaments as well common, that is, coming from the muscles, as proper, descending alwayes from the upper to the lower. But these same bones are some lesse than othersome, besides they are hard and without marrow, gibbous on the outside for the security and comlineffe of the hand, but hollow on the inside for to give way to the tendons going into the fingers. These bones are disposed in two ranke. The first Ranke containes onely three, but the second five. The three of the first Ranke are thus arayed, or placed, that one of them may receive the Appendix *Styloides* of the Cubite; the other the Ell and the Wand together, and the third may be received by the Wand. But three of the five bones of the second order susteine the foure bones of the afterwrest & are knit to the same by *Synarthrosis*, after which manner of connexion they are joynted to the bones of the first ranke; the fourth sustaines the first bone of the Thumbe to which also it is coarticulate by *Synarthrosis*; the fift and last is seated on the inside against the Ell, chiefly above that bone of the first order, which receives the Appendix *Styloides* of the Cubite, this is the least and weakest of them all by reason of its gristley substance, which makes the Ring with certaine Ligaments running from one of the inner sides of the wrest to the other.

What the
Annulus or
Ring is,

This Ring is placed there as well for the preservation of the sinewes, veines & Arteries passing under it (least when we leane upon our hand, or wrest, these parts should be hurt by compression) as also for the commodity of the Action of the muscles bending the finger, which in the performance of their action & the contracting themselves might deform the hand by their passing forth of the Cavity of the wrest. For what attraction soever is made by strings, if it be free and not hindered, is according to a streight line.

Now follow the bones of the second part of the hand, or of the afterwrest. These are foure in number, gibbous without, but arched within, or hollow in the middle; for hence is the palme of the hand, or certainly the greater part thereof; their ends next the fingers are somewhat remote from each other, that in these clefts the Muscles *interossei* might finde a place and seate. But these ends have each an Appendix, as you may perceive in the Skeleton of a childe. But you must note that by the first bone of the wrest or Afterwrest, we meane that which is in the foreside of the hand, that is to say, that in the wrest which lies under the Thumbe, and that in the Afterwrest, which is seated under the forefinger, as these which keepe in order the fingers which exceed the rest in necessity and dignity.

The bones of
the Afterwrest

After these follow the fiftene bones of the fingers, that is, three in each, which are hollow and fistulous full of a thin and liquid marrow, and not of grosse and thicke as in the arme and thigh. They are outwardly gibbous, but inwardly hollow and flat for the fitter seate of the Tendons ascending amongst the fingers on the inside even to the upper joynt. The which that nature might the better strengthen and preserve, it hath produced from the lips of the inner Cavities of these bones a membranous & strong Ligament, which running overthwart from one side to the other doth so straitly close the Tendonsto their bones, that they cannot goe forth of their places, or incline to either side. They are connexed on the outside, that they might be more fit to hold any thing. But for the first bones of the 4 fingers and Thumbe, foure are joynted together with so many bones of the afterwrest by *Synarthrosis*; for the bones of the afterwrest are moved by no manifest motion; the fift is knit to the second ranke of the bones of the wrest, therefore that bone cannot be attributed to the afterwrest, as some have written, seeing it hath manifest motion and is knit by *Diarthrosis*, but the bones of the afterwrest are onely fastened by *Synarthrosis*. For the second and third ranke of bones of the fingers, they are knit the second to the first, and the third to the second by *diarthrosis* and *Arthrodia*, because besides the manifest motion they have, they receive each other by a superficary cavity, as those of the first ranke, the bones of the afterwrest, and those of the second ranke, them of the first; those of the third them of the second. And all the bones of the fingers are larger and thicker at their basis, but smaller towards the ends; and they are bound by Ligaments especially proper, which (as we said formerly) descend from the first to the second; so that the last bones seeing they have not to whom to communicate their nerve, make & produce nailes thereof.

The bones of
the fingers,

Whence the
nails are ge-
nerated.
The *Ossa*
Sesamoidea,
or Seed-bones.

Wherefore the nails are generated by the fibers of the Ligaments, and the excrement of the tendons which are terminated at the bottom of the nails. Now remaine the *Ossa Sesamoidea*, or seed-bones: these are 19. in number in the inner joynts of each of the hands, and as many in each foote, viz. two in the first joynt of the foure fingers and in the second of the thumbe, and one in each of the rest. For the inner side of the joynts, you may for the most part observe one in each of them; yet in the second joynt of the thumbe there be two, above the two tendons, which are somewhat gristlely.

Their use.

They are made for this use, that they firme and strengthen the joynts, so that the bones of the fingers may not be turned awry, or thrust forth of their places by strong and violent motions, as it sometimes happens in the whirle-bone of the knee. They are called *Sesamoidea* from the resemblance they have to the seed of *Sesamum*, which is somewhat long and flat.

The Figure of the bones of the Hand. The 1. shewes the inside of the right hand, and the 2. shewes the backe side of the same.

The Charact. 1, 2, 3, 4, 5, 6, 7, 8. shew the eight bones of the wrist.

A, 1, 2. The first bone of the Afterwrest lying under the thumbe.

I. II. III. IIII. The 4. other bones of the Afterwrest annexed to the fingers.

B, C. The two bones of the thumbe.

D, E, F. 1, 2. The 3 bones of the forefinger, which are the same in the other fingers.

M, 1, 2. A little bone sometimes fastened outward-

ly at the joynt of the eight bone of the wrist.

N, 1. A proccesse of the eight bone of the wrist, swelling out into the ball of the hand.

O, 1. A proccesse of the fift bone of the wrist, from which a Ligament proceeds.

P, 2. An Appendix of the bones of the wrist, by which they are articulated to the afterwrest.

Q, 2. Another appendix which with its head entreteth into the Cavity of the finger.

R, 1, 2. The space betweene the bones of the afterwrest.

S, 1, 2. Two litle seed-bones set on the inside and outside of the first joynt:

T, 1. Two seed-bones in the first of the 4 fingers.

V. V. 1. One seed-bone in the second and third joynt of the fingers.

CHAP. XXVIII.

Of the muscles which seated in the Cubite move the Wand
and with it the Hand.

The muscles of
the Cubite.

Now must we describe the muscles of the formerly described parts, that is, those which are seated in the Cubit, which are carried to the inside of the hand, and those which are called the *Interossei*. Now the muscles of the Cubit are 14, 7 externall, and 7 Internall; two of the seven externall doe primarily twine

twine or turne up the Wand, and secondarily or by accident turne the Palme of the hand upwards, wherupon they have called them *supinatores*, or turners up of the hand; two extend the wrest, wherupon they are named *Carpitenses* or the Wrist-extend-ers; two the fingers, whence they are stiled *Digitumtenses* or finger-stretchers; to cōclude, the seventh & last is termed *Abductor* or *Obliquator externus*. The first of the two *supinatores* is called the Long, or Longest, because it descends from the outside of the Arme above the processes thereof, and is inserted by a round and strong tendon into the lower Appendix. The other descends obliquely from the outward and upper procelle of the arme, and is inserted at the third part of the Wand by a membranous & fleshy tendon before and on the inside thereof. The upper of the two Extenders of the Wrist, descending above the wand from the externall and upper procelle of the arme is inserted by two Tendons into the first and second bone of the After-wrist, which susteine the fore and middle fingers.

The *Supina-
tores*.
The *Carpi-
tenses*.
The *Digitum-
tenses*.
The *Obliqua-
tor externus*.
The first of
the *Supina-
tores*.
The second.
The upper of
the *Carpitena-
tores*.

The other & lower, descending from the same place as the former, above the Cubit is inserted into the fourth bone of the Afterwrist which beares up the litle finger. These muscles whilest they move alone, that is, each with his Antagonist, to wit the wrist-benders, they move obliquely upwards or downwards the whole hand properly so called. The first and greater of the Extenders of the fingers, or finger-stretchers arising from the *Olecranon*, or bone of the Cubit, descends superficially betweene the two bones of the Cubite even to the wrist, in which place it is divided into 4 tendons, which passing under the Ring seated there, end (each distinguished by a common ligament above the bone of the Afterwrist) in the last joynts of the foure fingers, adhering neverthelesse firmly to the bones, which are above these joynts.

The lower.

The greater
of the *Digitum-
tenses*.

The other which is the lesser arising almost in the middle of the Wand, goes obliquely to the Thumbe into which it is inserted by two Tendons; the one thicker which is inserted into the root thereof, and drawes it from the other fingers; the other slenderer continued even to the upper joynt thereof, and by its action extending the Thumbe.

The lesser.

The seventh which is the *Abductor* or *Obliquator*, is seated at the hinde part of the hand, that is, towards the litle finger; we have often found this divided in two, yea verily we have found it triside, or divided into 3. this yeare in three or 4 dead bodies. one portion thereof went to the lower side of the Ring-finger with two Tendons, the other in like manner to the middle and fore-fingers, and the third to the Thumbe.

The *Obliqua-
tor*, or *Ab-
ductor externa-
mus*.

And for all that it is thus divided, yet some have taken and accounted it for one Muscle, because it hath one originall and action, which is to draw the fingers backwards; some have added to this the extender of the Thumbe by reason of their common originall; and thus of 4. muscles they have made one divided into 7. tendons, distributed, as is formerly shewed. But when the *Obliquator* of the Ring-finger is wanting, as it often happens, the extender of the finger supplyes that defect by certaine productions ostendinous strings. But some also have written, that this muscle which we said hath 7. tendons, is onely a production of the deepe fore muscle, which should be sent through the space betweene the bones of the Cubit; yet I had rather make it a muscle of it selfe, by reason of its strait adhesion with the bones of the Arme and Wand. And let thus much suffice for the externall muscles of the Cubit, which you may comprehend in the number of seaven, as we have done; or in sixe, if you take away one of the 4. or in nine, if you had rather resolve it into 4. with *Galen*; or in eight, if you divide this muscle onely into three. For in very deed the *Abductor* or *Obliquator* of the Ring-finger is not often found in men.

Now must wee come to the inner muscles of the Cubit, the first of which commeth passeth the skin of the palme of the hand, whence it is called the *Palmaris*. The second and third joynd by the communion of their action turne downe or prone the Wand, and consequently the hand, so that the palme lookes towards the feet, wherupon they are called *Pronatores*.

The muscles
of the inner
part of the
Cubit.

The 4. and 5. joynd also in affinity of action bend the Wrist, wherefore they are named *Carpiflexores*, Wrist-benders. The sixth and seventh are appointed to bend the first, second, and third joynts of the fingers, wherefore they are rearm'd

The Palmaris *Digitum flexores, Fingerbenders.* For their originall, the *Palmaris* the least & uppermost of them all, descends fleshy from the hinde proceſſe of the inner arme, & a litle after ending in a long and slender Tendon, it is ſpent in the ſkin of the Palme of the hand even to the roots of the fingers. For it was neceſſary that this ſkin ſhould ſtraitly cohere with the ſubjacent parts, not onely for the fitter taking or comprehension of any thing, leſt that ſkin in holding ſhould be wrinkled & drawne away from the palme and fingers, and ſo be an impediment; but beſides that the hand might have a more exact ſenſe to diſtinguiſh of hot, cold, moiſt, dry, ſmoth, æquall, rough, ſoft, hard, great, litle, and ſuch other qualities. Then follow the two *Pronatores*, of which one called the round, comes obliquely from the inner ſide of the hinde proceſſe of the arme almoſt to the middle of the Wand, to which it adheres by a membranous & fleſhy tendon, even to the place appointed for inſertion. The other ſquare three or foure fingers broad, yet ſomewhat ſlender, ſeated within under all the muſcles which deſcend on the inſide to the wreſt or fingers, upon the ends of the bones of the Cubit, aſcends tranſverſe from below the Ell, unto the top of the VVande where it ends in a membranous tendon. Both the *Carpiflexores*, or VVreſt-benders ariſe from the hinde, but inner proceſſe, and deſcende obliquely (the one more, or leſſe than the other) the one alongſt the Ell, but the other alongſt the wande; and that which deſcends alongſt the Ell, is inſerted into the eight bone of the wreſt, which we ſaid made part of the Ring; the other which followes the VVande is inſerted with his greater part into the bone of the wreſt, and with the reſt into the firſt bone of the After-wreſt which ſuſtaines the fore-finger.

The Digitum flexores.

The Sublimis Digitum flexor.

The profundus Digitum flexor.

Now remaine the *Digitum flexores*, or Fingerbenders, which becauſe they lye upon one another, the upper is called the *Sublimis*, but the lower the *Profundus*. The *Sublimis* or upper, ariſing from the inner part of the hinde proceſſe of the arme, and from the upper parts of the Ell and VVand deſcends betweene theſe two bones of the Cubit even to the wreſt and Ring; divided into 4. tendons it is inſerted into the ſecond articulation of the foure fingers, which it bends by the force of this his proper inſertion; as alſo the firſt, as well by the power of the common ligament, as by certaine fibers cōming from it, which it ſends thither by the way in its paſſage. But theſe 4 tendons nere unto this their inſertion are divided into two, ſo to give paſſage and ad ſtrength to the tendons of the Deep muſcles deſcending into the third and laſt joint of the fingers.

But this ſame *Profundus* or Deepe muſcle ariſing from the upper and inner parts of the Ell and Wand, deſcends betweene theſe two bones under the *Sublimis*, alſo undivided even to the wreſt, where it is divided into 5. Tendons which it brings forth under the common Ligament, and the diviſions of the Tendons of the *Sublimis* even to the laſt joynt of the fingers, which they bend, by this their proper inſertion, as alſo the bones of the firſt and ſecond joynts of the fingers by the meanes of the common Ligament and fibrous productions which they beſtow upon them by the way. Beſides theſe forementioned there is ſeene alſo a certaine membranous Ligament which engirts the tendons in the compaſſe of the fingers.

CHAP. XXIX.

Of the Muscles of the inside of the hand.

The number of the muscles of the inside of the hand.

The Thenar.

He muſcles of the inſide of the hand are 7 in number; the firſt is called *Thenar* becauſe it makes the greater part of the Palme; the ſecond from the ſite is called the *Hypothenar*; the third the externall *Abductor* of the Thumbe. The 4. other are called by reaſon of their figure the *Lumbrici* or wormy muſcles, or the *Adductores*, or Drawers of the foure fingers to the thumbe. Now the firſt called *Thenar*, thicker than the reſt, ariſes from all the bones of the Afterwreſt, taking its beginning from that bone which beares up the Ring finger, whence aſcending alongſt the Vitall line even to the end therof at the firſt bone of the After-wreſt ſuſtaining the fore finger, & it is at length inſerted into the laſt joynt of the Thumbe by the longſt fibers

fibers, but by the middle and shortest fibers almost into all the inner part of the first bones of two joynts, and by reason of this, the thumbe is drawne to the other fingers, and from them againe by his lower originall.

Some devide this muscle into three, by reason of his diverse actions, making the first to arise from the roote of the bone of the afterwrest which beares up the ring finger; but the other from that middle bone of the afterwrest which sustaines the middle finger; but of the third, from the upper end of that bone which underprops the fore finger, and that the infertion of them all, is, as we formerly mentioned. But the former opinion likes me better, both for thunning confusion, and abbreviating the doctrine of the number of muscles.

The *Hypothenar* arises from the fourth bone of the afterwrest, and that bone of the wrest which sustaines it, and then with its longest fibers, it is inserted into the second joynt of the ring-finger, and by the shortest into the first, through which occasion, as also in respect of its twofold action, some have devided it into two, that the one of them might leade it from the rest, and the other might draw it to the thumbe.

The third the externall *Abductor* of the thumbe, descends from the first bone of the afterwrest, into the first and second joynt of the thumbe; wherefore some have devided it into two. The *Lumbrici*, or foure externall *Abductores* of the foure fingers arise from a membrane, investing and binding together the tendons of the *Digitum-flexores*, or fingerbenders, and at length on the sides towards the thumbe even by a small tendon, running even to the second joynt of the foure fingers.

Now the *Interosses* of the afterwrest, remaine to be spoken of; these are sixe, two in each of the spaces betweene the fingers, one Internall, the other Externall, of which the Internall descending with oblique fibers from the side of the first bone of the afterwrest, goes also into the sides of the fingers, that so it may the more closely binde together the bones of the afterwrest, whose action is manifested when wee thrust our fingers into a strait glove, or when we bend our hand. Some thinke that it helpes also the drawing of the fingers towards the thumbe. The Externall ascends also by oblique fibers from the sides of the second bone of the afterwrest, to the first joynts of the fingers, intersecting the internall which we now described after the manner of the letter X, for to extend the palme of the hand, and helpe the drawing away of the fingers from the thumbe.

Here concluding the description of the muscles of the whole hand taken in generall, you shall note that they are 39. in number, that is, eight appointed to move the arme; foure ser to move the cubit in generall; seven seated on the outside of the cubit, and as many on the inside in the same cubite, moving the wand, and with it the hand; seven on the inside of the hand: and lastly, the sixe *Interosses*. Some encrease this number, saying, there are nine on the externall part of the cubite, and eleven on the inside of the hand.

CHAP. XXX.

A Description of the Legge taken in generall.

After the hand follows the description of the legge. Wherefore to take away all doubtfulnesse, we will first define the legge; then devide it into the parts more and lesse compound; thirdly we will prosecute all things common to all these parts; fourthly, those which are peculiar to each, and then, God willing, we will give an end to our Anatomy.

Now this word *Crus*, or Legge, is used two manner of wayes, that is, either generallly and specially, and specially againe after two sorts, that is, either absolutely and simply so, or with an adjunct. It is simply taken for all that which is betweene the knee and the foote. But with an adjunct for the greater bone thereof. But the legge taken in generall, is the instrument of going, containing all whatsoever is from the hipps, to the very ends of the toes. It is devided into three great parts, that is to say,

The thigh.
The legge or
shanke.
The foote,

say, the Thigh, the Legge, or Shanke, and the Foote. By the thigh we meane that which lies betweene the hippe and the knee. By the legge, properly so called, or shanke, that which is contained betweene the knee and the foote. By the foote all from thence to the ends of the toes.

The division
of the foote.
The Instep.

Againe, they deuide the foote into three parts, that is, the *Tarsus* or Instep, the *Pedion* or top of the foote, and the *Digiti pedum*, or toes. We understand by the instep, that which is contained in the first seven bones, which answers in proportion to the wrest of the hand. By the top of the foot, that which is comprehended in the five following bones, which is answerable to the afterwrest. That which remaines, we call the toes. But because all these parts have other common and proper parts, we will onely follow the distribution of the veines, arteries, and nerves; seeing we have sufficiently explained the rest, when we described the containing parts of the body in generall.

The top of
the foote.
The toes.

CHAP. XXXI.

A Description of the Crurall veine.

The begin-
ning of the
Crurall veine.
The two
branches
thereof.

The Crurall veine begins then, when the hollow veine passing forth of the *Peritoneum*, and stretched to the hanch bone, and the sides of the *Pubis* in the groine, is first divided into two large branches; the one of which descends on the inside alongst the bones of the whole legge, together with the artery and nerve; the other runnes downe outwardly and superficially alongst the legge, betweene the fat lying under the skinne, and the muscles even to the foote, and is spent in the skinne thereof. This because it is alwayes apparent and manifest, is called properly by the Greekes *Sapheia*, but commonly *Saphena*.

By what
veines, the
matter causing
those tumors
called *Bubones*
flows downe.

This veine by the way presently at its originall is devided into two branches, the one internall, the other externall; of which the internall is spent upon the *Bubones*, and other glandules of that place and the skinne, and by this branch come the defluxions called *Bubones*; the other branch is waisted in the fore and utter skinne of the upper part of the thigh; then a little lower, that is, about the bredth of three or foure fingers, it is gathered againe into one branch made of many little ones, which is spent in the fore and hinde skinne of this thigh. Thirdly, a little below the middle of the thigh it is againe devided into two other branches, of which the one goes into the skinne on the fore side, and the other on the hinde side. Fourthly, it is distributed by two other small spriggs into the skinne, on the fore and hinde part of the knee; which oftentimes are not found, especially when the *Poplitea* or ham veine, is somewhat larger than ordinary. Fifthly, a little below the knee, it produces two other branches, lying upon each other in their passage out into the fore and hinde skinne of that place. You must note, that branch which runnes into the skinne of the hinde part, is carried by a certaine other sprigge, which it produces, into a branch of the *Poplitea* passing forth of the two twin muscles. Sixthly, in the bigger part of the calfe of the legge, it is divided into two other branches, which in like manner are distributed into the skinne, as well in the fore side as the backe side of the legge.

Where and in
what diseases,
the *Sapheia*
must be open-
ed.

At length after many other divisions, which for brevitie sake, I omit, when it arrives at the fore and inner side of the ankle (where it is commonly opened in the diseases of the parts below the midriffe which require bloud-letting) it is parted into two other branches, the lesser of which descends to the heele, the other in many spriggs is spent upon the skinne of all the upper and lower part of the foote and toes.

Towhat plas-
ces, and by
how manifold
deviſions the
internall
branch of the
crurall veine
goes.
Ischiadica ve-
ne.

The second branch of this Crurall veine, which wee said descends within together with the artery and nerve, even into the foote, is devided; first peircing somewhat deepe in, it produces foure divarications; one internall descending below the originall of the *Sapheia* into the muscle called *Obturator externus*, and into certaine other externall muscles. The three other runne outwardly, the first towards the huckle bone, by which the *Ischias* is made, the two other into the fore muscles of the thigh, neither are these spriggs far remote from one another. Secondly, all that branch

is devided into two other branches, the one above, the other below, an artery alwayes accompanying it; the lower of which is spent upon many of the hinder *Muscula Genae* muscles of the thigh, ending nigh the ham. The upper, besides, that it bestowes many branches upon the fore and inner muscles of the thigh, descending to the ham, it produces the *Poplitea* or ham veine, made sometimes of two branches, the one proceeding from above, and the other from below. This *Poplitea* descending by the bending of the ham, is spent one while upon the skinne of the calfe of the legge, another while upon the knee, otherwhiles encreased with branches of the *Saphia*, it goes on the outside of the ankle to the skinne, on the upper side of the foote, and sometimes on the lower. *Poplitea Vena*

Thirdly, a little below the originall of the ham veine, and under the bending of the knee, it brings forth the *Suralis*, which is bestowed upon the muscle of the *Sura*, or calfe of the legge, and upon the skinne of the inner side thereof, and of the foote continued sometimes even to the inner part of the great toe. *Suralis Vena*

Fourthly, under the head of the hinder appendix of the bones of the legge, it produces betweene the setwo bones, another veine, which nourishing the fore muscle of the legge, is consumed upon the foote.

Fifthly, and lastly, it brings forth the *Ischiadica maior* or greater *Ischias*, which is devided into two branches of an unequall bignesse; the larger whereof, from his originall descending alongst the inner part of the legge bone, insinuates it selfe under the muscles of the calfe, betweene this and the heele, into the sole of the foote, upon which it is wasted, devided into ten small sprigs, two for each toe; the other being the lesser descending alongst the *Perone*, or shin-bone, is consumed betweene it and the heele, yet sometimes it is produced, not onely even to the muscle the *Abductor* of the toes, but also by five furcles, even to the fourth toe, and the sides of the middle toe. *Ischiadica maior*

CHAP. XXXII.

The Distribution of the Crurall Artery.

He crurall artery arising from the same place whence the crurall veine proceeded, and descending with the internall crurall veine is distributed as followeth.

First, into the muscle of the thigh, which spreading it selfe through the muscles therof meets with the utmost *hypogastrica*, descending with the veine through the common hole of the huckle and share bone, and is joyned with it. *Arteria musculi*

Secondly, when it arrives at the ham, betweene the *Condyles* or processees of the legge, it sends two branches into the knee.

Thirdly, a little after it produces another branch, which it sends to the exterior muscles of the legge, and when it arrives at the middle of the legge, it is devided into two branches, betweene the twin muscles and *Soleus*, the one internall, the other externall; the internall, some furcles communicated by the way to the parts by which it passes, but specially to the joynt of the ankle, stretches it selfe over the sole of the foote, betweene the lower extremity thereof and heele, whither, when it arrives it is divaricated into five furcles, of which it bestowes two on the great toe, two on the next, and one on the middle toe. The externall descending in like manner to the sole of the foote, betweene the *fibula* and the heele, besides other sprigs, which it may spread by the way, it produces one without on the joynt of the ankle, another in the muscle, the *Abductor* of the toes, to the wrest and backe of the foote. But the remainder is devided into five portions, of which two are sent to the fourth, and two to the little toe, and one to the middle.

CHAP. XXXIII.

Of the Nerves of the Loynes, Holy-bone and Thigh:

The five conjugations of the nerves of the loynes.

Here arise five conjugations of nerves from the loynes, devided into externall & internal branches; the externall are disseminated into the *Rachita* or chin muscles, the muscles *Semispinatus* and *Sacer* and the skinne lying over them. The internall are sent into the oblique ascendent and transverse muscle of the lower belly, into the *Peritoneum*, into the loine and chest muscles arising there, but after a different manner; for some are absolutely carried thither, as the nerves of the first conjugation of the loynes, and oftentimes also of the second, but that sometimes they send a small sprigge to the testicles, when the Costall have sent none thither; but some lower are partly distributed there, and partly sent some other way; for the greater portions first united amongst themselves, then presently with the portions of these of the holy-bone, goe into the thigh, as we shall shew in the distribution of the nerves of the holy-bone.

Where the testicles have their nerves.

The conjugations of the nerves proceeding through the holybone.

Now from the holy-bone, proceede fixe conjugations of nerves, reckoning that for the first which proceeds from the last *Vertebra* of the loynes, and first of the holy-bone; and that the fixte which proceeds from the lowest part of the holy-bone, and the first of the rumpe; these conjugations of nerves are devided into externall and internall branches.

An Anatomist call axiome,

The lesser externall passing forth by the externall and hinder holes of the holy-bone, are distributed into the parts properly belonging thereto, to wit, the muscles and skinne thereof; for every nerve by the law of nature first and alwayes yeelds to the neighbouring parts, that which is needefull, then presently to others as much as it can.

Wherefore if thou wouldst know whence each part hath his vessels at the next hand, that is, the veines, arteries and nerves, thou must remember the site of each part and the course of the vessels, and to consider this, that the veines and arteries as speedily and conveniently as they can, insinuate themselves into the parts, sometimes at the head or beginning, somewhiles by the middle, or extremes thereof, as there is occasion.

But a nerve principally enters a muscle at the head thereof, or at least not farre from thence, but never by the taile, whereby it may easily be understood by what branch of each veine, artery, and nerve, each part may have nourishment, lift, and sense. The other internall branches of the foresaid conjugations goe, especially the foure uppermost united from their originall with the three lowermost of the loynes, into all the legge, as you shall presently heare. But the two lower are consumed upon the muscles called *Lervateres Ani*, the *Sphincter* muscle of the same place; besides, upon the muscles of the yard, and necke of the bladder in men, but in women upon the necke of the wombe and bladder.

For these parts admit another in their bottome from the costall nerve, being of the sixth conjugation of the braine; these thus considered, let us come to the nerves of the thigh, which (as we said) from their first original, as it were compacted and composed of the greater portion of the three inner and lower branches of the loynes, and the foure upper of the holy-bone, are devided in the thigh into foure branches, of which the first and higher descending from above the *Peritoneum*, to the little *Trochanter*, is wasted upon the inward and superficially muscles of the thigh, and the skin which covers them a little above the thigh.

The second, descending with the crurall veine and artery by the groine, is devided into two branches like as the veine, the one internall, the other external, of which the internall descending with the veine and artery is sent into the inner and deepe muscles of the thigh ending above the knee. But the externall descending superficially with the *Saphaia*, even into the foote, gives branches by the way to the skinne which covers it.

The third seated under these former, passing by the hole common to the share and hanch,

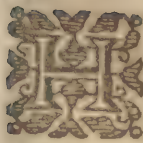

hanch-bone, send s certaine branches to the groines, to the muscles called *Obturatores*, to the *Tricipites*, and sometimes to the muscles of the yard, and it ends at the midst of the thigh.

The fourth, which is the thickest, solidest, and hardest of all the nerves in the body, descending wholly from the productions of the holy-bone, and descending outwardly betweene the lower part of the same bone, and the *Os Ilium*, or Hanch-bone to the thigh, bestowes certaine sprigges to the hinde muscles thereof proceeding from the protuberation of the *Ischium* or huckle-bone, and in like sort it gives other-some to the skinne of the buttocks, and also to the skinne covering the forementioned muscles.

A little after, it is parted into two branches descending undevied even to the bending of the knee, they both are communicated by diverse furcles of the muscles of the legge; yet so as the lesser produces another branch from the rest of the portion thereof descending on the fore part of the legge, alongst the shin-bone unto the top of the foote, where it is devided into tenne furcles scarce apparent to the sight, two running to each of the toes. The other greater descending in like manner in the remainder of its portion by the hinde part of the legge into the sole of the foote, casts its selte with the veines and arteries betweene the heele and legge bone; where first devided into two branches, each of which presently parted into five, send two sprigs to the sides of the toes. And these are the most notable and necessary distributions of the vessels and nerves; we purposely omit others which are infinite, and of which the knowledge is impertinent.

CHAP. XXXIII.

Of the proper parts of the Thigh.

AVING explaned the common parts of the legge in generall; now wee must come to the proper, beginning at the Thigh. The proper parts of the Thigh, are muscles, bones, and ligaments. But because the demonstration of the muscles is somewhat difficult, if we bee ignorant of the description of the bones from whence they arise, and into which they are inserted; therefore we judge it worth our labour, first to shew the bones, and the dearticulation of these of the Thigh; beginning with these bones which are knit with the upper part of the holy-bone. And they are two in number, on each side one, commonly called the *Ossa Ilium*; each of these is composed of three bones, of which one is the upper, another the lower and anteriour, and the third the middle, and after a manner the posteriour. The upper by a particular name is called the *Os Ilium*, the hanch-bone, and it is the largest and biggest, having a gristlely appendix in the compass thereof, even to the connexion it hath with the other neighbouring bones, whole upper part we terme the right line thereof; but the *basis*, which is adjoynded to it by *Symphysis*, we call the lippe or brow therof, because it stands both somewhat out and in, after the manner of the brow. But that which lies betweene the *basis* and straight line we name the ribbe; this same upper bone hath two hollow superficies, the one internall, the other externall. The connexion thereof by *Symphysis*, is twofold, the one with the upper part of the holy-bone; the other with that bone wee called the middle, and after some sort the posteriour; which taking its beginning from the narrower part of the *Os Ilium*, makes that cavity in which the head of the thigh is received; this cavity the Greekes call *Coryle*, the Latines *Acetabulum*, and it is ended by the side of the hole common to it, and the share-bone; this middle, and in some sort posteriour bone is called properly and particularly the *Os Ischy*, or huckle-bone, and contains nothing else but the forementioned cavities, but that on the hinde and lower part thereof, it brings forth a proceffe, which adjoyndes it selfe to the share bone at the lower part of the common hole, in which place it appears very rough and unequall, and it is called the tuberositie of the huckle-bone, at whose extremity also it brings forth a little head somewhat resembling the proceffe of

Of how many bones the *Ossa Ilium* consist. What the *Os Ilium* strictly taken is.

What the line, lippe, brow, and rib, of the *Os Ilium* are.

The *Os Ischyum*, or huckle-bone.

The *Os pubis*,
or share-bone.

of the lower jaw called *Corone*. The third bone named *Os pubis* or the share-bone, stretches it selfe even to the highest part of the *petten*, where meeting with the like bone of the other side, it is united to it by *Symphysis*, after which manner also, all these three bones are united; it is reported, that this bone opens in women in their travell, yet hitherto I can finde no certainty thereof.

The Figure of the Thigh-bone.

A 1, 2. The head of the thigh going into the cup of the hip-bone.

B, 2, A sinus in the head of the thigh, into which is inserted a round Ligament.

C 1, 2, The conjunction of the appendix of the thigh with the bone it selfe.

D 1, 2, 3, the necke of the thigh.

E, F, the two lower heads of the thigh.

G, 1, 2, The conjunction of the lower appendix.

H, 1, 12, A sinus betwixt the two heads of the thigh.

K 2, A part of the lower head of the thigh, from whence the first muscle of the foote doth proceede.

L 2, Another part from whence the second and first muscles arise.

M 2, Another part to which the Tendon of the fifth muscle of the thigh is in-fixed.

N 1, 2, A sinus of the outward side of the head for the fourth muscle of the legge.

O 2, A sinus of the inside

through which the tendons doe passe. **P 2,** A protuberation at which the said tendons are reflected. **Q 2,** the upper processe of the thigh, and betwixt **Q** and **D** is the sinus. **R 1, 2,** the union of the processe with the thigh. **S S 2,** a rough line from the impression of the externall processe. **T 1,** the anterior impression of the internall processe. **β,** betwixt **T** and **V** another impressiō higher than the former. **V 1, 2,** the fourth impressiō in the toppe of the processe. **X 3,** Four **X**, shew the foure appendices of the thigh. **Y 3,** Three **Y**, shew the three heads of the thigh. **Z Z 3,** Two processe of the thigh. **a 1,** the interior processe of the thigh. **b 1,** the conjunction of the processe with the thigh. **cc 2,** a line descending obliquely from the inner processe. **dd 2,** a line running through the length of the thigh. **e 2,** the largeness of the thigh in this part. **f 1,** a roughness from which the eighth muscle issueth. **g, b 5,** a knob of the Whirle-bone going into the sinus marked with **I**, which is betwixt the heads of the thigh. **i 5,** a sinus fitted for the inner head of the thigh. **k 5,** a sinus agreeing with the externall head of the thigh. **l 5,** the lower asperity or roughness. **m 4,** the foreside of the pattell or whirle-bone rough and unequall.

You may perceive a manifest separation of these three bones in the *Skeleton* of a child; for in those who are of more yeares, the gristles which runne betwene these connexions turne into bones.

Now follows the thigh-bone, the biggest of all the bones of the body; it is round, and so bended, that it is gibbous on the exterior and fore part thereof, that so it might be the safer from externall injuries; but on the hinde and inner part, it is hollow or sinuous, like to the backe of an Asse, whereby the muscles might have a more commodious originall and infertion.

The descrip-
of the thigh-
bone.

That sinuous part a little below the midst thereof, is divided into two lines, the one whereof goes to the internall tuberositie, the other to the externall of the lower appendix of the same thigh. These are chiefly to be observed, because the oblique fibers of the vaste muscles thence take their originall.

Besides, this bone hath two appendices in the ends thereof, as easily appears in a child's thigh; the upper appendix, makes the round head of the thigh it selfe, which (as every other appendix) seated upon a long necke, is received in the cavitie of the hanch-bone by *Enarthrosis*; it is staid and fastened there by two sorts of ligaments, of which the one is common, proceeding from the muscles, which descend from above, about the necke thereof; the other is proper, which is twofold, that is, one membranous and broad, proceeding from the whole cavity of the orbe, or cuppe, descending about all the head of the thigh, above the necke thereof; the other thicke and round, descending from the second cavity of the *Coryie* it selfe, which is extended, even to the common hole at the top of the head thereof.

The two ap-
pendices of
the thigh-
bone.

Besides, under this head, that bone hath two proceses, the one great and thicke, the other little and short.

The two pro-
cesses of the
thigh-bone
make the two
Trochanters.

The greater seated in the hinde part, is called the great *Trochanter*; the lesser situate in the inner part, is named the little *Trochanter*.

But you must note, that the great *Trochanter*, on the higher and hinde part thereof, which lookes towards the head of this bone, makes a certaine small *sinus* or bosome, into which the twin muscles and others, whereof we shall hereafter speake, are implanted; we must also consider the multitude of holes encompassing this necke, betwene the head and the two *Trochanters*, which yeeld a passage to the vessels, that is, the veines, arteries, and nerves, into the marrow of the bone it selfe, whence the marrow it selfe becomes partaker of sense, especially on that part which is covered with a coate, and the bone lives and is nourished.

Whence the
marrow be-
comes parta-
ker of sense.

The other Appendix of the thigh, that is, the lower, is the greatest and thickest, rising, as it were with two heads, which are divided by two cavities, the one superficialie and on the fore side, whereby it receives the whirle-bone of the knee; the other deepe, and on the backe part, by which it receives the gristely and as it were bony ligaments, proceeding from the eminencie which is seene betwene the two cavities of the upper appendix of the bone of the legge, which *Hippocrates*, lib. de *fracturis*, calls in his tongue *Diaphysis*.

CHAP. XXXV.

Of the muscles moving the thigh.

The muscles of the thigh are just foureteene in number, that is, two bend it, whereupon they are called the *Flexores*, or benders; three extend it, whereupon they are called *Tensores*, extenders; three move it inwards, driving the knee outwards, and drawing the heele inwards, as when wee crosse our legges; yet some make these three one, and call it the *Triceps*, or threeheaded muscle. Sixe spread it abroad, and dilate it, as happens in the act of venery.

Their number.

Fourte

Four of these are called *Gemini* or Twins, by reason of the similitude of their thicknesse, originall inserrion and action; the two other are called *Obturatores*, because they stop the hole which is common to the share and backe bones.

The two
flexores.

Now one of the two *Flexores*, being round, descends on the inside with fibers of an unequall length from all the transverse proceffes of the loines, above the hinde commissure of the hanch and share-bones, and is inserted into the little *Trochanter*; the other broader and larger from the originall passes forth of the whole lippe, and inner brow of the hanch-bone, and filling the inner cavity thereof, is inserted above the fore part of the head of the thigh, into the little *Trochanter* by a thicke tendon, which it with the fellow muscle lately described, produces, even from the fleshy part thereof, wherefore you neede to take no great paines in drawing, or plucking them away.

The three
Tenses.

The three *Tenses* or extenders, make the buttocks, of which the first being the thicker, larger, and externall, arising from the rumpe, the holy-bone, and more than halfe of the exterior and hinder lippe of the hanch-bone, is inserted by oblique fibers, some foure fingers breadth from the great *Trochanter* at the right line, which we said, resembled an Asses backe.

The second, which is the middle in bignesse and site, descends from the rest of the lippe, and from the fore and outward ribbe of the hanch-bone, and above the midst of the bone, is inserted into the upper part of the great *Trochanter* by a triangular insertion above the upper and exterior part thereof.

The third being lesser, shorter and thinner, lying hidde under these former, proceeds from the middle of the externall surface of the hanch-bone, and then is inserted into the greater part of the right line of the great *Trochanter*.

These three muscles have a great and large originall, but a narrow insertion, as it were by oblique fibers.

Three Intro-
movers.

Then follow those three muscles which move the thighs inwards, straiten and crosse then, so that the knee stands forwards or outwards, but the heele is drawne inwards, as you may understand by their insertion, although some thinke otherwise. But these three muscles by their originall, partly fleshy, and partly membranous, arise from the upper and fore part of the circumference of the share-bone, and thence are inserted into the hinde line of the huckle-bone, some higher than othersome; for the lesser and shorter stayes at the roots of the little *Trochanter*, the middle descends a little deeper, the 3. with the longest of his fibers, descends even to the midst of the line.

This if it be so, that is, these muscles proceeding from the fore and upper part, to be inserted into the hinder line of the huckle-bone, whilest they alone performe their action, and draw the thighs together, they will turne them outwards, just so as when we put them acrosse, but they will not draw one heele to another, and put the heele outwards, for such like motion is performed by the inner *Vaste* muscle of the thigh, moving the legge. Now follow the fixe which move the buttocks.

The movers
of the but-
tocks.

The first, and higher of the *Quadrigemini*, or the foure twin muscles, passes forth of the commissure of the holy-bone, with the bone of the rumpe, or rather from the lowest extreme of the holy-bone, and thence it is inserted into the cavity of the great *Trochanter* by a tendon of a sufficient largenesse.

The second proceeding from the hollow part or fissure, which is betweene the extremity of the huckle-bone, and the tuberositie, or swelling out of the same, is inserted in like manner into the cavity of the great *Trochanter*.

The third, ascends from the inner part of the swelling out of the huckle-bone, a little above, betweene the two *Trochanters*, into the cavity of the greater of them.

The fourth, and last, the lowest and broadest of them all proceeds from all the exterior protuberancie of the huckle-bone, and thence is inserted into the great *Trochanter*, and these foure muscles lie hid under the thicke and more eminent part of the buttocks; wherefore that you may the better shew them, they must be turned up towards their originall.

The two Ob-
turatores.

The two *Obturatores* remaine to be spoken of, that is, the internall and externall, both which arise from the circuite and circumference of the hole which they stoppe, which as wee said is common to the share and huckle-bone,

bone, but the internall ascends to the exterior roote of the great *Trochanter* by the middle fissure betweene the upper part of the protuberancy of the hucklebone, and the spine which stands up in the hinder basis of the hanch-bone.

But the externall proceedes from the exterior cavity, and the middle space betweene the tuberosity of the huckle-bone and cavity thereof, and is inserted in the lower part into the cavity of the great *Trochanter*, together with the *Quadrigeni*.

If you would plainly see the exterior *Obturator*, you must either cut off the beginning of the three-headed muscle, or handsomely pluck it away, and then extend it, and turne it up; The internall is easily discerned when the bladder is taken away.

CHAP. XXXVI.

Of the bones of the Legge, or Shank.

Those which would describe the muscles of the legge, ought first to describe the bones thereof, beginning at the *Rotula*, or whirle-bone of the knee.

What the *Pec-
tella*, or whirle-
bone of the
knee is.

This bone is gristlely on the outside, and round in compasse, but on the inner and middle part after some sort gibbous, but somewhat flatted at the sides, that so it may be fitlier applied to the joynt of the knee, and fitted within the anterior cavity of the two *appendices* of the thigh, and the upper and foremost of the legge.

The use thereof is to strengthen the joynt of the knee, and to hold the legge at his due extent, so that it may not be bended so farre forwards, as it is backwards.

The use thereof.

The bones of the legge are two, the one thicker, called by the particular and proper name, the *Os Tibia* or legge-bone; the other which is lesler, is termed *Perone*, or *Fibula*, but commonly the lesser *scapula*, (and in English it may be termed the shin-bone.) The thicker being hollow and marrowie, is seated in the inner part of the leg, having two processes, the one bigger, the other lesse.

What, and
how many
bones the legge
hath.

The legge-
bone.

The bigger seated on the upper part of the bone, and conjoyned to it by *Symphysis*, makes two superficial and side cavities disioyned by an indifferent rising; wherefore this bone is connect to the bone of the thigh by *Ginglymos*. For in the cavities thereof it receives the lower and hinder protuberances of the Appendix of the thigh-bone, but the middle eminencie thereof, is received by it betweene the two protuberances thereof.

This joynt is strengthened, not onely by the force of the tendons, or muscles ending there, but also of three strong ligaments, of which one proceedes from all the externall, another from all the internall part of that connexion; the third which we, out of *Hippocrates*, called *Diaphysis*, from the distance or space betweene them. The other processe of the legge-bone, which we called the lesse, seated in the lower part thereof, makes as it were a double cavities, whereby it receives the *Astragalus* or *Pasterne* bone; but on the inside it makes the ankle, as the *Perone* makes it without: betweene these ancles the *Astragalus* is received on the sides, and turned as the nut in a Crosse-bow, as often as there is neede to bend or extend the foote. Besides, this same leg-bone, being triangular hath three eminencies made in the shape of an Asses back; the sharper descends alongst the fore part, called by the Greekes *Anticnemion*; the second resides on the inner part, and the third on the outer; all these must be diligently observed, and chiefly, that on the fore part; because it is as a guide and rule to a Chirurgion in the well setting of a broken legge. The *Perone*, or shinne-bone, is seated, as it were, on the outside, and as behinde the legge-bone; it hath also two *appendices* hollow on the inside, but gibbous on the out. This bone by the upper of these is fastened and inserted under the inner, and in some sort the hinder *appendix* of the legge-bone, so that it is in no sort articulated with the thigh, but

What *Diaphy-
sis* is.

The *Perone* *fi-
bula*, or shin-
bone.

serves onely in stead of a leaning stocke. But by the lower, this same bone is not onely received in the lowest part of the legge, or ankle, or pasterne bone, but also receives part thereof, which is joined on the same side with the heele, especially then when we bend our foote outwards.

This bone is fastened to the forementioned bones by *Synarthrosis*, but bound by strong ligaments proceeding from the same bones, and mutually sent from one to another, or if you had rather, from the upper into the lower, as we said in the arme. But this same *fibula* or shin-bone is also triangular, having three lines, of which one stands outwards, another on the fore-side, and the third behinde.

CHAP. XXXVII.

Of the Muscles of the Legges.

Their number.

ALL the motions of the legge are performed by eleven muscles, of which there be sixe on the fore-side, and five on the hinde. But of these, some move the legge onely, as those which take their originall from the bone of the thigh; others truly move the legge, but with the thigh, as those which arise above the thigh, that is, from the hanch, huckle, and share-bones.

The Longus.

The first of these on the fore-side, called the Long, but commonly the *Sutorius* (or Tailor-muscle by reason of its action) it arises from the lower and fore extremity of the spine or appendix of the hanch-bone, and descending obliquely above the other muscles, is inserted by a large and membranous tendon, into the fore and inner part of the legge under the knee; the action thereof is to crosse the legges, but being first bended by the muscles presently to be treated of, it helps also the three headed muscle in the performance of the forementioned action.

The Membranousus.

The second of these fore muscles is termed the *membranosus*, or membranous, because it is wholly such, unlesse at the originall where it descends fleshy from the roote and basis of the above mentioned spine of the hanch-bone, and that obliquely with its membranous and broad tendon (mixed with the common coat of the muscles) into the outward part of the legge, which it moves outwards, as also the thigh with the foure twin muscles; for as we have in another place observed, of two oblique motions, concurring in one, is made a right motion; and besides, almost all the motions of the body, are thus performed; the muscles which performe such motions are placed and opposed in an oblique site, as may be perceived by the motions and site of the muscles of the hand taken in generall.

The Rectus.

The third, called the *Rectus*, or right (because it descends above the *Crureus*, alongst the right fore-line of the thigh, betweene the two *Vastæ* muscles) comes forth betweene the extremity of the appendix of the hanch-bone and cavity thereof, with a very strong ligament, and then is inserted into the fore part of the legge, passing over the midst of the whirle-bone of the knee; it extends the legge, with the three following, but by accident it may helpe the bending of the thigh.

The two Vasti.

The fourth and fifth are called *Vasti*, Vaste or huge muscles, by reason of their largenesse; the one of these is internall, the other externall: they both arise with right fibers, from their originall, but with oblique at their insertion, by reason whereof they both seeme to have a compound action from a right and oblique motion; the right helping for the extension of the legge, but the oblique to draw one knee to another, or to desioyne both the knees; the internall comes by its right fibers from the root of the little *Trochanter*, but by its oblique from the inner descendent line of the thigh. The externall passes forth by its right fibers from the root of the great *Trochanter*, but by the oblique from the externall descendent line of the same bone. But all these fibers are in certaine places so mixed with the *Crureus* that they cannot be separated unlesse you violate the one of them; they goe into the legge (each on his side) above the whirle-bone of the knee alongst the sides of the right muscle, with which it makes an unseparable tendon, as you shall presently

The Crureus.

heare. The sixth and last of these fore muscles called the *Crureus*, or Thigh-muscle, (by

(by reason of the strait and firme adhesion, which it hath with the thigh-bone, which is by some called *Crus*) from the space betweene the two Trochanters descends under the right muscle, and two vaste muscles into the fore part of the thigh, even to the whirle-bone of the knee. But we must note that these foure last muscles make a common thicke and broad tendon with which they couer the *Pateſſa*, or whirle-bone, and all the fore dearticulation of the knee, that they cannot be separated without tearing; wherefore we must thinke that this tendon, serves the knee for a ligament; now all these muscles performing their action together, extend the legge. The five hinder muscles follow to be spoken of, of which three arise from the tuberositie of the huckle-bone, going into the inner part; the fourth from the middle of the *Pubis*, called *Biceps*, that is, the two headed muscle into the outside of the legge. Of the internall, one passing frō the forementioned tuberositie, descends ligamentous even into the midst of the thigh, and then becoming fleshy, is inserted by its tendon, after the manner we formerly mentioned.

The three Internall.

The other being slender, passing forth also from the same place, with its tendon, is inserted with the tendon of the long muscle, and ends in the inner part of the legge, which with its companion, it drawes inwardly, and brings to the other, which same thing it performs in the thigh, by the helpe of the three headed muscle.

The third, being the inner, or hinder, descends from the middle part of the share-bone, with a broad and slender ligament, and is inserted with a round tendon, into the inner part of the legge after the manner of the fore-mentioned.

The fourth called *Biceps* takes one of the two heads, of which it consists, from the last mentioned tuberositie; the other from the outer line of the thigh, but is inserted into the externall part of the legge, as we formerly said.

The *Biceps*, or two-headed muscle.

The fifth and last called the *Popliteus* descends obliquely fleshy from the externall condyle or knot of the thigh, into the inner and hinder part of the legge, at the joyning thereof to the shinne-bone; the action thereof is, to draw the legge, after a manner inwards.

The *Popliteus* or ham muscle.

CHAP. XXXVIII.

Of the Bones of the Foote.

 The Order of Anatomy requires, that we now prosecute the muscles moving the foote; but because we should in vaine deliver their insertion, the disposition and condition of the bones of the foote, not being first known, wherefore it first behoves us, to set forth their description. Therefore the bones of the foote are fixe and twenty in number, distinguished into three ranks, that is, the bones of the *Tarsus* or Instep, are seven; these of the *Pedum*, the afterwrest, or backe of the foote, five, and those of the toes foureteene. Of the seven bones of the instep, there are 4. named, and 3. unnamed. The first of the named immediately following the bones of the legge, is called *Astragalus*, the pasterne, or ankle-bone. This hath three connexions, one, as we said before, in the upper and broader part with the bones of the legge, of which it is received; the other in the lower and hinder part, by which it receives the upper and inner processe of the bone of the heele; the third on the fore side by which it is received in the cavities of the *Os naviculare* or *Scaphoides*, that is, the boate-like-bone. By the first connexion the foote is extended and bended; by the second it is moved with the heele to the sides: the two first connexions are by *Diarthrosis*, the last by *Synarthrosis*. But it is strengthened by strong and broad ligments, descending, and ascending from one bone into another; also they are strengthened by membranes, muscles and tendons, descending to the foote, above and under these joints. But this bone hath 3. processes, as 3. seete fastened to the bone of the heele; of which the first and least is under the outer ankle; the bigger (which *Galen* saith, makes a round head, fastened on a long necke) looks towards the fore part of the foote, over against the great toe, and the next toe to it; the middlemost is at the heele, behinde the legge-bone.

des* or Die-
bone.

The *Os in-
nominata*, or
namelesse
bones.

The bones
of the foote
or *Pedium*.

The bones of
the toes.

I passe over in silence many other things, as the smoothnesse and asperity or rough-
nesse of the bone, which I had rather you should learne by ocular inspection, than by
booke. The second bone lying under this is called the *Calcaneum*, or heele-bone, being
the biggest of all the bones of the foote, upon which all the body relies when we go.
It hath two upper processes, the one great, the other little. The great is received in
the hinde and outer processe of the *Astragalus*; the lesser is received on the inside in
the 3. processe of the same bone, which we said had a round head fastened to a long
neck. Besides, it is round on the hinde part, and much disioyned from the legge-bone,
but on the fore and longer part, it is knit by *Synarthrosis* to the Die-bone, whose lower
and inner part, it seemes to receive; the superficies thereof is wholly unequall, and
rising up with many swellings. On the inner side it makes as it were a channell, so to
give way, as well to the vessels as tendons going to the sole of the foote and toes.
Lastly, we must consider the holes by which the vessels passe into that bone to give it
nourishment; by reason of which vessels the fracture of this heele-bone, is very
dangerous, because of the pressing and contusion of the vessels, as *Hippocrates* shewes.
For the ligaments of this heele, or heele-bone they are such, as these of the *Astraga-
lus*, to wit, tendons, membranes and ligaments properly so called, comming from
one bone to another. The third bone of the foote is named *Scaphoides* or boate-
like, from the resemblance it hath to a boate, for on that part which lookes towards
the posterne bone, it is hollow; but on that part which is next the three *Innominata*,
or namelesse bones (which it sustaines, and of which it is received, as it in the cavity
thereof receives the head of the *Astragalus*) it is gibbous like the bottome of a boate.
The connexions thereof are by *Synarthrosis*, and they are strengthened by the fore-
mentioned ligaments; this same bone is arched on the upper part, but somewhat
hollowed or flatted below: the inner part ends in a point, like the prow of a ship, but
the outer obtuse like the sterne of a shippe. The fourth bone of these which have
names, is called the *Cuboides*, from the resemblance of a Die; although that simili-
tude be very obscure. On the fore part it sustaines the toes; which by a certaine pro-
portion to the fingers of the hand, may be called the Ring and little toes, but it is su-
stained on the hinde part, with the backe part of the heele; on the inner side it is joy-
ned with the boat-like-bone, and that namelesse bone which sustaines the middle toe;
on the outside, it produces a rising like the backe of an Asse, which on the lower part
is extended transversely all the length thereof; at the two sides of this eminency or ri-
sing, there are two small cavities, in the forme of a channell. The first and the greater
of the *Os innominata*, or namelesse bones, sustaines the great toe; the lesser and se-
cond, the next toe thereto; the third and middle in biguetle, the middle toe. These
three bones are arched on their upper part, but somewhat hollowed below. They are
knit to the three forementioned bones by *Synarthrosis*, of which they are received,
but on the hinde part with the boate-like bone which they receive. Now we must
come to the bones of the second ranke, that is, of the *Pedium*, or backe of the foote;
these are five in number, bearing up the five bone of the toes. They are somewhat
gibbous on their upper part, but hollow below; each of them hath two processes at
the end thereof, by the lower and first of which they receive the three namelesse and
Die-bone, but by the upper made into a round head, they are received of the first
bones of the toes. Their connexions, whether with the toes, or bones of the instep,
are by *Synarthrosis*. The ligaments as well proper as common are such, as we said of
the former. The bones of the third order now remaine to be spoken of, which wee
said, make the toes, and they are foureteene, two of the great toe, but three of each
of the other toes. The first is somewhat longish, but the rest are very short, ex-
cept that of the great toe, all of them on the upper side are round and convexe, but on
the lower somewhat hollow, and plaine long wise, that the tendons which bend
them, may passe more straightly and safely without inclining to either side, even to
their furthest joynts; although such passages are much helped by the membranous
and common ligament, which rising from the sides of these bones, involves these
tendons, as we mentioned in the fingers. To conclude, each of these bones the last ex-
cepted, have a double connexion by *Diarthrosis*, they are all unequall in their bignes,
that is, thicke at their beginning (where they receive the heads of the precedent
bones,

bones, upon which they move, as a doore upon the hinges) and so they grow smaller towards the ends, but by their ends, they are received of the following bones: at their ends they rise into two eminencies on their sides; distinguished by a cavity betweene them, through which occasion they are farre thicker at their ends, than in their middle.

The Figure of the bones of the Foote properly so called.

Figure 1. and 2. shew the bones of the right foote fastened together their upper face and their neather face.

Fig. 3, 4, 5, and 6, shew the upper, lower, inner and outer sides of the Talus or pasterne.

Fig. 7, 8, 9. sheweth the same sides of the Heele.

Fig. 10, and 11. sheweth the forward and backward side of the boate bone.

Fig. 12, and 13. shew the fore and back part of the wrest made of foure bones.

ABCD 3, 5, 6. The protuberation of the Talus joyned to the appendix of the leg-bone, and of this protuberation foure sides.

EE, 3, A sinus insculped in the protuberation of the Talus.

FF 3, two bunching parts of the Talus.

G 3, the inner side of the protuberation of the Talus crufted over with a gristle, joyned to the inner ankle.

H 6, The outward sinus of the protuberation of the Talus covered over with a gristle, and receiving the inner ankle.

I 3, A rough sinus of the Talus, receiving a gristly ligament from the inner ankle.

K 6, a sinus of the Talus receiving a gristly ligament from the outward ankle.

LM 5, 6, two sinus in the hinder part of the Talus.

N 3, 4, 5, 6, the necke of the Talus or pastern bone.

O 3, 4, 5, 6, the head of the Talus going under the sinus of the boate bone.

P 7, 8, 9, the head of the bone of the heele crufted over with a gristle, and going under the sinus of the Talus or the pasterne bone.

Q, 4, a large sinus of the Talus receiving the head of the heele.

R 7, 8, 9, a sinus of the heele whereto the lower part of the head of the Talus is joyned.

S 4, the lower part of the head of the Talus going into the sinus of the heele.

TT 4, a sharpe sinus of the heele receiving a gristly ligament from the pasterne bone.

XYZ 2, the place of the heele.

YZ 2, Y 8, Z 9, a proceffe of the heele made for the production of muscles.

X 4

ab 7.

a b 7 8, 9, from *a* to *b* the distance of the upper part of the heele. *e* 8, 9, the hinder part of the heele. *d* 2, 8, the inner side of the heele. *e* 8, the place where the tendons that run to the bottome of the foote are reflected. *f* 7 8, the utter side of the heele. *g* 1, 7, 9, here the tendons of the 7 and 8 muscles of the foote are stretched out. *h* 7, the forepart of the heele which is joyned to the pasterne bone. *i* 7, that part of the heele which is joyned to the Cube-bone. *k* 11, the *sinus* of the Boat-bone receiving the head of the *Talus*. *l m n* 10, three surfaces of the Boat-bone lightly prominent, which are articulated to the bones of the wrest. *o p* 11, the upper part of the Boat-bone regarding the top of the foot. *q r* 10, and *q* 11, his lower part. *q* 10, 11, A *sinus* through which the first muscle of the foote is led. *s t u* 13, the plain surfaces of the three inner bones of the wrest whereby they are articulated to the Boat-bone. *x* 13, a shallow *sinus* of the Cube-bone whereby it is articulated to the heele, *a^β* 12, the place of the Cube bone to which that bone of the Afterwrest is joyned which supporteth the last Toe save one. *γ* 12, 13, the place of the Cube bone where the third bone of the wrest is articulated. *δ* 12, 13, that part of the Cube bone which respecteth the outside of the foote. *ε* 12, 13, the surface of the Cube-bone in the upper part of the foote. *ζ* 2, 13, that part of the Cube bone which regardeth the earth. *η* 2, a *sinus* of the Cube bone at which the tendon of the seventh muscle of the foot is reflected. *B* 13, a proceffe of the third bone of the wrest wherein to the first muscle of the foot is inserted. *Γ* 12, the place of the inner bone of the wrest to which that bone of the Afterwrest which sustaineth the great Toe is coupled. *κ* 12, the place of the second bone of the wrest whereto the bone of the Afterwrest that supporteth the fore Toe is articulated. *Λ* 12, the place of the third bone of the wrest whereto that bone of the Afterwrest which supporteth the middle toe is articulated. *μ* 1, 2, a small bone whereby that bone of the Afterwrest which sustaineth the little toe is joyned unto the Cube bone. *ν* 1, 2, the distances betwixt the bones of the Afterwrest. *ξ* 1, 2, the heads of the bones of the Afterwrest which enter into the besomes of the toes. *π* 2, a proceffe of the bone of the afterwrest wherein the tendon of the seventh muscle of the foote is implanted. *ρ* 2, a proceffe of the Bone of the Afterwrest, which sustaineth the little toe, which proceffe receiveth the tendon of the eighth muscle of the foote. *ς, γ, υ* 1, 2, the three bones of the foretoe. *ϕ, ω* 2, two seede bones placed under that bone of the afterwrest which sustaineth the great toe, *ϑ* 2 under *X*, a seede bone set to the second joynt of the great Toe. *Γ* 1, 2, the *Talus* or pasterne. *Δ* 1, 2, the Heele. *Θ* 1, 2, the Boat-bone. *Α, Ξ* 1, 2, the bones of the toes. *Φ, Χ* 1, 2, two bones of the great toe I, II, III, IV, V, I. the five bones of the afterwrest.

The Seed-bones of the foote:

The twofold use of the seete.

The Ligaments by which their connexions are fastened, are such as the former; The *Ossa sesamoidea* or Seed-bones of the feet are like in number and site to these of the hands. But this is to be noted, that those Seed-bones which are in the first articulation are somewhat bigger than the rest, and they are round and longish on the out side, but smooth and hollow on the inside, seated between two cavities, encompassed by three risings, of which two are on the sides, and the third in the midst of the extremity of the first bone of the *Podium*, which chiefly beares up the great toe. To conclude, before we come to speake of the muscles, we must observe that the foote was made for two commodities. The first is to stay and beare the whole body when we stand, for which cause nature set not the great toe contrary to the other, as it placed the Thumbe on the hand. The other is for apprehension, or taking hold of, wherefore nature framed and made the foote and these moveable and joyned in the toes, as in the fingers of the hand. Besides also for that we must goe upon our feet, Nature hath made them in some places hollow on the lower side, & in other some plaine in a triangular figure, that so our feet may carry us over every soile, plaine mountainous, equall and unequall, through all parts of the world.

CHAP. XXXIX.

Of the Muscles moving the foote.

THe muscles of the Legge moving the foote are absolutely nine, three in the fore part and sixe in the hinde. Two of the three fore muscles bend the foote, when they joyntly performe their action, but when severally, each drawes it to his side; the third chiefly extends the Toes, for other whiles it seemes by its slenderer and longer Tendon (which exceeds not that bone of the *Pedium* which susteines the litle Toe) to helpe also to bend the foote.

The first is called *Peroneus*, because it descends alongst the bone *Perone*; the other the *Tibialis anticus*, for that it descends along the *Os Tibia*, or bone of the Legge. The third from its action is called the *Digitumtensor*, or Toe-stretcher. For their originall the *Peroneus* which seemes to have two heads, descends from the upper appendix of the *Perone* or shin bone by its first head, but by the other from the middle of the same bone from the fore side into the hinde, as the superficies shewes which passes betweene the fore and outward line of the said bone; but after it arives at the lower and hinder appendix of the same bone, behind the outer Anckle it produces two tendons, which by the guidance of the Ligaments as well proper, as common, goe, the thicker under the sole of the foote, ending in the Die-bone and that bone of the *Pedium* which susteines the great Toe; the lesser goes on the outside to the Die-bone, & the last & least bone of the *Pedium* which beares up the litle Toe, sometimes a slender portion thereof is produced even to the side of the litle Toe, extending it and drawing it from the rest. The *Tibialis anticus* or Fore legge muscle proceeding from the upper and outer appendix of the Leg-bone descends above the surface of the same bone, which is betweene the fore and outer line to which it adheres, as also to that surface even to the midst, from which place it produces one tendon, which descending on the fore and lowest part, ends on the outside into two of the nameles bones, that is, into the first which is the thicker, and into the middlemost, but besides by a slender portion thereof it is extended into the first and greater bone of the *Pedium*, so to extend the great Toe, drawing it inwards to the other foote. And this muscle with the precedent bends the foote, if they both performe their parts at once; but if severally, each drawes the foote towards his side. The third which is the *Digitumtensor*, or Toe-stretcher, is two fold; the one takes its originall from the top of the Legge, and running alongst the shin-bone and passing under the ring, carries it selfe into the foote, in which it ends by five tendons going to all the joynts of the Toes, and by a sixth at that bone of the *Pedium* which susteines the litle Toe, whereby (as wee formerly said) it helpes the bending of the foote. The other descends into the midst of the shin-bone, and somewhat fastened thereto by one tendon passing under the Ring it goes to the great Toe. But you must note that all these Tendons have nervous, ligamentous and fleshy fibers so separated from each other, that they can equally alone performe their function, as if they were more distinct muscles. And wee must thinke the same of the rest which have distinct Tendons presently from their fleshy part.

The sixe hinde muscles follow, of which the two first are called the *Gemelli* or Twins by reason of the similitude of their thicknesse, originall, insertion and action. The third is called the *Plantaris*, because it is spent upon the sole of the foot, as the *Palmaris* upon the palme of the hand. The fourth is termed the *Soleus* or sole muscle by reason of the resemblance it hath to the fish of that name. The fift the *Tibialis posticus* or hindlegge Muscle which descends alongst the backe part of the leg-bone. The sixth and last the *Digitumflexor* or Toe-bender, equivalent to the Deepe muscle of the hand, some make but one muscle of this and the *Tibialis posticus*, which produces three tendons; others had rather make three, as thus, that one should be the *Tibialis*, the other the bender of foure Toes, the third the bender of the great Toe.

Now for the two *Gemelli* or Twins, the one is internall, the other externall; the internall passes forth from the roote of the inner Condyle of the Thigh; but the externall

Their number.

Musculi Peronei.

Tibialis anticus.

The Toe-stretcher is two fold.

The 6 hinde muscles.

The 2 Gemelli or Twins muscles.

In what place
the kibes breed

externall from the externall Condyle; and from this their originall presently becoming fleshy, especially on the out side, they meet together a litle after in their fleshy parts, and with the *soleus* they make the thicke and great Tendon at the midst of the legge, which from thence is inserted into the backe part of the heele; in this very Tendon breed painfull kibes. The action thereof is, to helpe our going by putting forth the foote, whilst it drawes the Heele towards its originall.

The *Plantaris*

The *Plantaris* the least and slenderest of them all, passes forth fleshy from the outward head of the legge-bone, and from thence the space of some foure fingers bredth it ends in a strong and slender Tendon, which it sends betweene the *Twin* and sole muscles to the sole of the foot, there to produce a membrane which covers the sole of the foote, and a muscle equivalent to the upper bender of the Hand.

The *Soleus*.

The *Soleus*, or sole muscle the thickest of them all, and seated under the *Twin* muscles, descends from the commissure of the legge and shin-bones, and about the midst of the legge, after it hath mixed his tendon with that of the *Twin* muscles, it runs into the foresaid place that it may extend the foote for the foresaid use,

The *Tibialis*
posticus.

The *Tibialis posticus* descends from the hinder appendix of the legge and shinbones, and adhering, to them almost as fare as they goe, by a strong Tendon, being as it were bony at the end thereof, it is inserted into the Boat-like bone and the two first names bones so to helpe the oblique extension of the foote.

The *Digitum*
flexor two-
fold.

The last being the *Digitum flexor* or Toe-bender is twofold, for one arises from the legge-bone, in that place where the *Popliteus* ends, and inserted into that same bone it goes even to the backside of the inner ankle & from thence into the joynts of foure of the toes. The other drawes his originall from almost the middle of the shin-bone, and somewhat inserted into it, it goes by the heele and pasterne bone to the great toe, mixed with the precedent; their action is to bend the first joynt of the Toes, rather by the force of the common Ligament, than by the small portion of the Tendon which ends there. But it is their action to bend the last dearticulation of the Toes by their proper insertion.

CHAP. XL.

Of the Muscles moving the Toes of the feete.

Their number.

Now follow the muscles moving the Toes; these are eight in number, one on the upper, and seven on the lower side. The first proceeds from the Pasterne, heele and Dic bones below the externall Ankle, or the Ligament of these bones with the Legge-bone, and obliquely stretched to the top of the foote is parted into five small tendons to

The *Abductor*
of the Toes, or
Pediosus.

the sides of the five toes, so to draw them outwards towards its originall, whereupon it is called the *Abductor* of the Toes, and also *Pediosus*, because it is stretched over the *Pedium*, or backe of the foote.

The *Flexor*
superior.

The first of the seven of the lower side called the *flexor superior* or upper bender, arises from the heele and stretched alongst the foote under the strong membrane, (which from the heele is straitly fastened to the extremity of the bones of the *Pedium* to strengthen the parts contained under it) is inserted by foure Tendons, at the second joints of the foure Toes which it bendes. Here you must note that neer the insertion thereof, this muscle divides it selfe, like that muscle of the hand which is called *sublimis*, that so it may give way to the Deepe, which (as we said) descends alongst the fingers, to which a certaine common membranous Ligament adjoynes it selfe, which involues and fastens it to the bone all alongst the lower part of the fingers, even to the last dearticulation.

The muscle
equivalent to
the *Thenar*.

The second equivalent to that muscle of the hand which is called *Thenar*, seated on the inner side of the foote, arises from the inner and hollow part of the heele and pasterne bones and ends in the side, and inner part of the great Toe, which it drawes from the rest, inwards. This may be divided into two or three muscles, as the *Thenar* of the hand, to draw the great Toe to the rest, as much as need requires, just as we said of the Hand. The third answerable to that of the hand which is named the *Hypothenar*, passes from the outer part of the heele and ascending by the sides of the foote it is in like manner inserted into the side of the litle Toe, so to draw it from the rest;

to which same action a certaine flesh contained under the sole of the feete may serve, which is stretched even to these Toes, that also it may serve to hollow the foote. The foure *Lumbrici* or wormy muscles follow next, which from the membrane of the Deep Toe-bender are inserted into the inner & side part of the foure Toes, so to draw them inwards, by a motion contrary to that which is performed by the *Pediosus*. The *Interosses* or bone-bound muscles of the *Pedium* or back of the foot, remaine to be spoken of: These are eight in number, foure above, and as many below, different in their originall, insertion and action; for the upper because they draw the foote outwards with the *pediosus*, arise from the fore and inner part of that bone of the *pedium*, which beares up the litle Toe (and so also the rest each in its order) and are inserted into the outward & forepart of the following bone. The lower on the contrary passe from the fore and outer part of that bone of the *pedium*, which beares up the Great Toe (and so each of the rest in its order,) but are inserted into the inner and upper part of the following bone, so with the wormy muscles to draw it inwards, or to hollow the foote as the outwards, or to flat the foote, as we said of the *Interosses* of the hand.

The 4 *Lumbrici*.

The description of the upper and lower *Interosses*.

CHAP. XLI.

An Epitome or brieve recitall of the bones in a mans body:

H He whole head which hath the least consists of 60. bones; but that which hath most of 63. that is, 14 of the *Cranium* or scull, 14 or 17. of the face, and 32 teeth; Of the bones of the scull there be 8 containing and fixe contained; the

The bones of the Scull, 14.

This first sheweth the forepart of the Sceleton of a man, &c.

The Declaration of these three figures put into one.

A 3. The Coronall Suture called in Greeke *σφαιραια*.

B 2 3. The suture like the letter Λ called *λαμδαιδης*.

C 2. The sagittall Suture called *ὄβελος*.

D 2, 3. The scale-like Conjunction called *λεπιδαιδης*.

a. 2, 3, *Os verticis*, or *synsippius*, the bone of the *Synsippus*, called *ὀσ βρεγματις*.

β. 1, 3. The forehead-bone, that is, *μετωπον*.

γ. 2, 3. The bone of the Nowle or *iris*.

δ. 2, 3. The bones of the temples or *κρανια*.

ε. 3. An appendix in the temple-bone like a Bodkin, called *σφυραιδης*.

ζ. 1, 2, 3. A proesse in the temple-bone like the teate of a dugged, called therefore *Mamillaris* & *μαστοιδης*.

η. 2, 3. the wedge-bone, called *σφηνοειδης*.

θ. 3, the stony part of the Scull.

ι. 3, a proesse of the wedge-bone much like the wing of a Bat, and therefore called *πτερυγιδης*.

F, 1,

The 2 and 3 Figures sheweth the backside of the Sceleton.
and the laterall part of the Sceleton.

F, 1, 2, 3. the yoke-bone ζυγωμα. G 1, 3. the lower jaw. I, K, L, M, N, 1, 2, 3. the backe or the spine, ραχίς. From I to K, the Necke, σπονδυλα. From K to L, the Rackebones of the Chest. From L to M, the rackebones of the Loynes. From M to N, the Holy-bone, ισχον. N, the Rumpe bone, κόκκυξ. O, 1, 3. the brest-bone, στήθον. P, 1, 3. the Sword-like gristle of the brest, ξιφοειδής Char. 1, 2, 3, as farre as to 12. in all three Tables, shew the twelve ribs of the Chest πλευράι. Q 1, the clavicles or collar bones, κλειδες. R, 1, 2, 3 the shoulder-blade, ομοπλάτης. A, 1, 2, 3, the upper proceffe of the shoulder-blade, or the top of the shoulder, called ἀκρομήμιον. V, 1, 3, The lower proceffe of the shoulder-blade: called ἀγκυροειδής. S, 1, 2, the bone of the arme, called *Humerus* and βραχίον. T, V, 1, 2, 3, the Cubit πῦχος. X, 1, 2, 3: the wand or the upper bone of the Cubit, called καρκίς. Y, 1, 2, 3, the ell or lower bone of the Cubit, called πῦχος. γ, 3, the proceffe of the Cubit, ὠλέκρανον. Ξ, 1, 3, the proceffe like a bodkin or probe, called εὐλαοειδής. ZZ: 1, 2, 3, the wrest καρπός. ΓΓ, 1, 3, the after-wrest μελανόσπον. ΔΔΔ. I, the fingers δακτύλοι. Θ, 1, 2, 3, the bones joyned to the sides of the Holy bone, on each side, distinguished as it were into three parts. ο, 1, 2, 3, the first part called the Hanch-bone, *Os Ilium*, λαγύρα. π, 1, 2, 3, the second part the bone of the *Coxendix* ισχίον. ς, 1, 2, 3, the third part the share-bone, *Os pubis*, ἴβαν. σ, 1, 2, 3, a gristle going betweene the conjunction of the share-bones. Λ, 1, 2, 3, the thigh, μηρ. τ, 1, 2, 3, the greater outward proceffe of the thigh called *Rotator* περιστάτης μέγας. υ, 1, 2, 3, his lesser

lesser and inner proceffe. Ξ , 1, 2, 3, the whirlebone of the knee, *Patella Rotunda*, ἐπικυλιν. Π , Σ , 1, 2, 3, the leg, *ἰνὴ μὲν*, Φ , 1, 2, 3, the inner & greater bone of the leg *περὶ ἄρην μὲν*, Ψ , 1, 2, 3, the utter and smaller bone of the leg, called the *Brace-bone*, *Fibula*, *περὶ ὀνὴ μὲν*, Φ , 1, 2, 3, the proceffe of the Leg or the inner ankle called *Malleolus internus*. X , 1, 2, the proceffe of the brace of the out-ward ankle, both of them are called in greeke, *σφυλὸν*. Ω , 1, 2, 3, the bone called the cockal, *Talus*, *balista*, *Os ἀσπὶ γαλ.* α , 2, the Heele *Calc*, *πέδιον*. β , 1, 3, the bone called *Os Naviculare*, *καρπιδὲς*. ϵ , 1, 2, 3, the wreat of the foot called *Tarsus*, consisting of foure bones, *περὶ δὲ*. δ , ϵ , f , 1, 2, 3, three inner bones of the wreat of the foot, called by some *χάλκοις*. g , 1, 2, 3, the utter bone of the wreat of the foot like a Dye, *κυκοίς*. h , 1, 2, 3, the afterwreat of the foote called *Pedium*, by some *μεταταρσ.* i , 1, 2, 3, the toes of the foote. k , 1, 2, 3, the seed bones of the foote, called *oscula sesamina*, *σπασμοίς*.

This figure sheweth the Sekeleton of the bones & gristles of a woman, that it may appeare all her bones are in proportion lesser than the bones of a man. But in this figure onely those parts are marked with letters wherein a woman differeth from a man in her bones and gristles.

- A, The sagittall suture descending into the nose, & dividing the fore head bone, which is sometimes found in women, very rarely in men, but alwayes in Infants.
- BB, the Chest somewhat depressed before, because of the Paps.
- CC, the collar bones not so much crooked as in men, nor intorted so much upward.
- D, the brest-bone perforated sometimes with a hole much like the forme of a heart, through which veines do run outward, from the mammary veines unto the paps.
- E, the gristles of the ribs, which in women are somewhat bony, because of the weight of the Dugs.
- F, a part of the backe reflected, or bent backward above the loynes.
- GG, the compasse of the hanch-bones running more outward, for the wombe to rest upon, when a woman is with child.
- HH, the lower proceffes of the share-bones, bearing outward that the cavity marked with K, might be the larger.
- I, the anterior commissure or conjunction of the share-bones filled up with a thicke gristle, that in the birth they might better yeeld somewhat for Natures necessity.

K, A great and large cavity circumscribed by the bones of the coxendix and the Holy-bone. L, The Rumpe or Coccyx, curved backward to give way in the time of the birth. M, the thigh bones by reason of the largeness of the foresaid cavity, have a greater distance betwixt them above, whence also it is that womens thighs are thicker than mens.

containing are, the *Os frontis*, or Forehead bone, the Nowle-bone, the two bones of the *Synsput*, the two stony bones, the Wedgebone, and the Sive-like or spongy-bone. But the contained are fixe shut up in the cavity of the Eares, the Anvile, Hammer and stirrop.

The bones of
the face 15.

For the bones of the face, there are six within or about the Orbe of the Eye, that is, on each side three; two bones of the Nose, two lesser Jaw bones, and two bigger, which are alwayes in beasts scene distinguished by a manifest difference, but it is so rare in men, that I have not found it as yet; therefore these onely are distinguished by manifest difference, two which containe all the upper teeth, the two inner of the palate, the two of the lower Jaw in children; And last of all the *Os Crista*, whence the middle gristle or partition of the nose arise.

The teeth 32.

The two and thirty teeth are equally distributed in the upper and lower Jawes; and of these there be eight shearers, foure fanges, or Dog-teeth, and twenty Grinders.

The bone
Hyoides

And there is another bone at the roote of the tongue called *Os Hyoides*, alwayes composed of three bones, sometimes of foure.

The bones of
the spine 34.

Now follow the bones of the Spine, or Back-bone, which are just foure and thirty, that is, seven of the necke, twelve of the Chest, five of the loines, six of the holy-bone; and foure of the rumpe. Besides there are two bones of the throate, or Collar bones.

2 Collers
bones.
The Ribs 24.
The bones of
the Sternon 3.

The Ribbes are twenty foure, that is, fourteene true and ten bastard ribs. The bones of the *Sternon* or Breast-bone most frequently three, other whiles seven, as sometimes in young bodyes.

The bones of
the whole
arme 62.

Hence comming to the Armes there are reckoned 62, beginning with the shoulder-blade; as there are two shoulder-blades; two Arme bones; foure bones of the Cubite; that is, two Ell-bones and two Wands; sixteene of the Wrest, eight of the Afterwrest, and thirty of the fingers: into this number also come the *Sesamoidea*, or seedbones, of which some are internall, & these alwayes twelve at the least, although somtimes there may be more found, a great part of which rather merite the name of Gristles, than bones; there are others externall if we beleeeve *Sylvius*.

The bones of
the whole leg.
66.

Now remaine the bones of the Leg, which (if we reckon the *Ossa Ilium* on each side three, as in yong bodies, it is fit they should) they are sixty six, besides the seed-bones, that is to say, two Haunch-bones, two share bones, two Huckle-bones, two thigh-bones, two Whirlbones of the knees, foure of the leg, that is two leg-bones, and two shin-bones. Fourteen of the Instep, as two heele, two pasterne, two boat-like, two Die, & six namelesse bones. Ten of the *Pedium* or back of the foote, that is, five in each foot; & twenty eight of the Toes: & as many seed-bones in the feet, as the hands enjoy. But I have thought good to adde these figures for the better understanding of what hath beene spoken hereof.

CHAP. XLII.

An Epitome of the names and kinds of composure of the bones.

What the
Sceletos is.

The bones are
composed two
manner of
wayes.

2. Sorts of Art
tication.

What *Diart
hrosis* and
Synarthrosis
are.

3. Sorts of *Dis
arthrosis*.

What *Enar
throsis* is.

BEcause it is as neceessary for a Chirurgion to know the manner of setting & repairing broken bones, as to put them in their places when they are dislocated, or out of joynt; but seeing neither of them can be understood when the naturall connexion of the bones is not knowne, I have thought it a worke worth my labour, breifly to set downe, by what and how many means the bones are mutually knit and fastened together. The universall composure and structure of all the bones in a mans body is called, by the Greekes, *Sceletos*. But all these bones are composed after two sorts, that is, by *Arthron*, an Articulation or joynt, and by *Symphysis* a naturall uniting or joyning together. There are many other kinds of both these sorts. For there are two kinds of Articulation, that is *Diarthrosis* or Dearticulation, and *Synarthrosis*, or Coarticulation; which differ as thus, Dearticulation is a composition of the bones with a manifest and visible motion; Coarticulation hath a motion of the bones, yet not so manifest, but more obscure. But these two do again admit a subdivision into other kinds. For *Diarthrosis* containes under it *Enarthrosis*, *Arthrodia* & *Ginglymos*. Now *Enarthrosis* or Inarticulation is a kind of Dearticulation, in which a deep

Cavity

Cavity receives a thicke and long head, such a composition hath the Thigh-bone with the Huckle-bone.

Arthrodia is when a lightly engraven civity admits a small and short head, such a connexion is that of the Arme-bone with the shoulder-blade; of the first *Vertebra* with the second. The Greekes have distinguished by proper names these two kinds of Cavities and heads; For they call the thicke and long head *Cephale*, that is, a Head absolutely; but the lesser they terme *Corone*, or *Coronon* which the Latines call *Capitulum*, a Little-head. But they call a deepe Cavity *Cotyle*, and a superficially one *Glene*. The third sort called *Ginglymos*, is when the bones mutually receive and are received one of another; as when there is a cavity in one bone, which receives the head of the opposite bone, and also the same bone hath a head which may be received in the Cavity of the opposite bone; such a composure is in the Cubite and knee, that is in the connexion of the Thigh-bone.

And thus much of Dearticulation and the three kinds thereof. *Synarthrosis* or Coarticulation, another kinde of juncture, hath also three kinds thereof (*Gal. lib. de Ossibus*) to wit, *Sutura*, *Gomphosis* and *Harmania*.

Suture is a composition of the bones after the manner of sowing things together, example whereof appeares in the bones of the Scull. *Gomphosis* is when one bone is fastened in another as a pin is fastened in a hole, after which manner the teeth are fastened in their sockets in both the Jawes. *Harmony* is when the bones are composd by the interposition of a simple line, after which manner many bones of the nose and face are joynd together.

Hitherto we have spoken of the first construction of the bones by articulation and the kinds thereof; now it followes we treat of *Symphysis*.

Symphysis, or Growing together as we formerly said, is nothing else, than naturall union of the bones; such union is made two manner of wayes, that is, either by interposition of no other thing; after which sort in succeſſe of time the bones of the lower law grow together, which formerly in children were manifestly distinguished; or by the mediation of some *Medium*; but that happens three manner of wayes, by interposition of three severall *Media*, as first of a Gristle, which kinde of union the Greekes call *Synchondrosis*, after which manner the Share-bones grow together and also some *Appendices* in young bodyes; secondly of a Ligament, and it is named by the Grecians *Syneurosis*, the name of a Nerve being taken in the largest sense, for sometimes it is used for a tendon, otherwhiles for a Ligament, otherwhiles for a Nerve properly so called and which is the author of sense and motion. But this *Symphysis* or union hath place by *Syneurosis*, or interposition of a Nerve in certaine bones of the *Sternon* and Haunch.

Thirdly, the bones grow into one by interposition of flesh, called in Greeke *Synsarcoſis*; thus the flesh of the Gums fastens the teeth and makes them immoveable. But if some be lesse pleased with this division, by reason of the obscurities, in which it seemes to be involved, this following expression comes into my minde, which I was first admonished of by *German Cortin* Doctor of Physicke, which if you well observe it, is both blamelesse and more easie for your understanding.

What *Arthro-*
dia is.

What *Cephale*
is.

What *Corone*
is.

What *Cotyle* is.

What *Glene* is.

What *Gingly-*
mos is.

3 Kinds of
Synarthrosis.

What a *Suture*
is.

What *Gom-*
phosis is.

What *Har-*
mania is.

What *Symphysis*
is.

Synchondrosis.

Syneurosis.

The things
signified by
word *Nerve*.
Synsarcoſis.

The bones, which as pillars susteine the fabricke of the whole body, are either,

or Conjoynd by that which they call *Arthrodia*, or Articulation, as when they so concur & are bound together, that some Heterogeneous substance may be noted betwixt them, but the bones thus composed are knit two manner of wayes, that is,

either more loosely as by *Diarthrosis*, that is a kind of Articulation not very strait, as by which it might have opportunity to preforme diverse motions: of this composure or Articulation of bones there are three kinds, as

or more straitly, as by *synarthrosis*, where the bones are more straitly knit so that they can performe no motions in the body. Of this Articulation there are also 3, kinds, that is

Enarthrosis, when the head of a bone is wholly received in the cavity of another, & hid therein, as the Thigh-bone is joynd with the Huckle-bone.

Arthrodia, when in a lightly engraven & not much depressed cavity, the head of another bone is not wholly hid, but only received in part thereof; so that unless nature had otherwise provided a sufficient receptacle for the head of this bone (as by the ligaments of the neighbouring Muscles) it would otherwise have bin in perpetuall danger of dislocation. Thus the Arme-bone is fastened to the shoulder-blade.

Gynglymos, when the bones mutually receive each other, such like composition hath the Cubit and Arme-bone.

Gomphysis, as when one bone so receives another as a Pin is fastened in the hole made by a peircer, thus the teeth are fastened in the Jawes.

Sutura, like a Saw, or teeth of a combe, as the bones of the scul are mutually knit together, or as scales, or tiles are laid, after which manner the stony bones are fastened to these of the *Synsiphia*. *Harmonia*, which is by interposition of a simple line, which parts bones abutting one upon another, as the bones of the Nose.

An Epitome or brieve recitall of all the Muscles of mans body.

As I have formerly reckoned up the bones, so here I have decreed to recite the muscles of mans body. Wherefore in the face we first meet with the broad or skin muscle, arising from the fleshy pannicle, & covering the whole necke & almost all the face. Then follow 4, pertaining to the upper eye-lids. In the Orbs of the eyes lye 14, that is 7, in each Orbe, of which 4 are called right, two oblique and one pyramidall. Then succeed 4 of the nose, two externall on each side one, and two internall, these draw it together and the other open it. After these come the ten muscles of the lower Jaw, of which two are called the *Crotaphitiæ* or Temporall; two *Masseteres* or Grinders; two round (which seeme to me rather to pertaine to the lips, than to this Jaw;) two litle ones hid in the mouth, arising from the winged proesse of the wedge-bone; two openers of the mouth being nervous or tendinous in their midst. Then follow the 8 muscles of the lips, that is, 4 of the upper and as many of the lower, shutting and opening the mouth. The tongue with his ten muscles is hid as it were in the den of the mouth. Wherefore the muscles of the whole face are 51. In the fore part of the neck are found the muscles of the bone *Hyoides* & throtle; now 8 muscles hold the bone *Hyoides* as equally ballanced; of which there are 2 upper arising from the Chin; 2 on the sides from the proesse *Styloides* perforated in their midst, through which the 2 openers of the mouth in that part nervous do passe; 2 arise from the *Sternō*, & lastly 2 from the upper rib of the shoulder-blade to the *Coracoides*, which also in their midst are nervous, in which place the two *Massoidei* lye upon them.

The

The Throate composed of three gristles hath eightene or twenty muscles, of which sixe or eight are common, and twelue proper; Of the common there are two above, two below, and two at the sides of the first gristle, to which wee may adde these two which serve for the opening of the *Epiglottis*, which are alwayes found in great foure footed beasts for to presse downe the *Epiglottis*.

The 13. of the
Larynx.

The proper are twelue which almost all of them come from the second gristle, so to be inserted into the first and third, of which some are before, others behinde the *Thyroides*. Besides these, there are the *Mastoidei* which bend the head.

The head is
moued by 14.
Muscles.

But in the backe part of the Necke there are twelue muscles also appointed for to move the head, so that in all there are fourteene muscles serving for the motion of the head, the two fore *Mastoidei*, and the twelue hinde Muscles, that is to say, the two *Splenij*, two *Complexi*, foure Right, and so many oblique which are very shorr, so that they passe not beyond the first and second *Vertebra*.

The 8. Muscles
of the necke.

The Necke hath eight Muscles, of which two are called the long, lying before upon the bodyes of the *Vertebra*; the two *Scaleni* which are at the sides; the two *Spinati* which runne alongst the Spine; the two transverse which goe to the transverse processes of the Chest.

The Muscles
of the chest 18.

The Chest hath 81 Muscles, of which some are on the fore part, some on the hinde, others on the sides; they are all combined or coupled together except the Midriffe. Now of these there are the two *Subclavij*; the two great Saw-muscles which proceed from the basis of the shoulder-blade; the foure litle *Rhomboides* or square muscles, that is, two above and two below; the two *Sacro-lumbi*; the two binders of the Gristles within the Chest:

Besides there are twenty and two externall and as many internall Intercoastall muscles; twenty foure *Intercartilaginei*, that is, twelue externall and as many internall; so that the Intercoastall, and *Intercartilaginei* are 68, which with the twelue before mentioned make the number of 80 Muscles. Adde to these the Midriffe being without an associate, and you shall have the number formerly mentioned; to wit, 81. But also if you will adde to these the Muscles of the lower belly, I will not much gainsay it, because by accident they helpe inspiration and expir-
ation.

The 8. muscles
of the lower
belly.

Wherefore of the eight muscles of the *Epigastrium*, there are foure Oblique, of which two are descendent and so many ascendent; two right, to which you may adde the two Assisting or Pyramidall muscles which come from the share-bone, if it please you to separate them from the head of the right muscles:

The 6. or 8. of
the loines.

There are sixe or eight Muscles of the Loynes, of which two bend the loines which are the triangular; the two *Semispinati*; two *Sacri*; two are in the midst of the backe, which for that cause we may call the *Rachite* or Chirre-muscles. Now, that hereafter we may severally and distinctly set downe the muscles of the extreme parts, will we come to the privities.

The two Cre-
masters of the
Testicles.

Where for the use of the Testicles there are two Muscles called the *Cremasteres*, or Hanging Muscles. At the roote of the yard, or *Perinaum*, there are foure others, partly for the commodious passing of the urine and seed, and partly for erecting the yarde. The *Sphincter* Muscle is seated at the Necke of the Bladder.

The three of
the fundamen-
te.

At the end of the right Gut are three Muscles, two *Levatores Ani*, or Lifters up of the fundament, and one *Sphincter* or shutting Muscle. Now let us prosecute the Muscles of the Extremities, or Limbs. But it will be sufficient to mention onely the Muscles of one side, because seeing these parts of the body are double, those things which are said of the one may be applyed to the other.

Wherefore the muscles of the Arme, beginning with these of the shoulder-blade, at the least, are 42. for there are 4 of the shoulder-blade: of the Arme properly or particularly so called, seven or eight; and there are three, foure, or five proper muscles of the Cubite, that is, appointed for the performance of the motions thereof; in the inner part of the Cubite are seven, and as many in the outer; but those of the hand are reckoned thirteene at the least.

The muscles
of the Arme in
generall 32.

The fourth of the shoulder-blade are the *Trapezius* resembling a Monkes Cowle, which moves it upwards and downewards, and drawes it backwards; the second is the *Levator*, or Lifter-up; the third the great *Rhomboides* lying under the *Trapezius*. The fourth, the lesser saw muscle which is inserted into the *Coracoïdes*. The arme is moved forwards, backwards, upwards, downewards and circularly.

The Pectorall muscle arising from the Clavicle, Breast-bone and neighbouring ribs, drawes it forwards; the *Humilis* or low-muscle comming from the lower rib of the shoulder-blade drawes it backwards; the *Deltoides* upwards; and the *Latissimus* downewards, and somewhat backewards. But the three seated about the shoulder-blade move it about; or circularly.

The *Epomis* or *Scapularis* upwards; the *Super-scapularis*, which may seeme two, backwards and downewards; the *Subscapularis* which is in the Cavities of the shoulder blade, forewards, so that by a certaine vicissitude and succession of action they move it circularly. Two muscles bend the Cubite; the one named *Biceps* or Two-headed, and the other *Brachialis* or the Arme-muscle; but one, two, or three muscles extend it; for if you have respect to the originall, this muscle hath two or three heads, but one onely insertion.

In the inside of the Cubite are seven muscles, one *Palmaris*, two wrest-benders; two *pronatores*, one square, another in some sort round; two finger-benders, and one *Abductor* or Drawer aside. These fourteene internall and externall muscles of the Cubite, doe not indeed move the Cubite, but onely seated there move the wande and with it the hand. These are the thirteene Muscles of the hand; the *Thenar* which may not only be divided into two, but into sixe, not only by the diverse actions it performes, but also by the branches divided by a manifest space betweene them; the second is called the *Hypothenar*, which lyes under the litle finger, as the *Thenar* doth under the Thumbe; the third is the *Abductor* of the Thumbe; then follow the foure *Lumbrici* and sixe *Interosses*, although eight may be observed.

The muscles
of the legge in
generall 50.

The whole Legge hath at the least 50. Muscles, for wee reckon there are fourteene muscles in the thigh; there are eleven made for the use of the Legge; there are nine seated in the Legge, three before and sixe behinde which serve for the use of the foot and toes; in the foote are seated sixteene. Therefore of the foureteene muscles serving the thigh two bend it, one called the *Lumbaris*, the other arising from the cavity of the Hanch-bone; but the three which make the Buttocks and the *Triceps* or Three-headed muscle, (which if you please, you may divide into three) extend it. Besides these the 4. twin muscles, and two *Obturator*s, of which the one is internall, the other externall, turne the Thigh about. The Legge hath eleven, that is, the Long, the Membranous, the foure *Postici* or Hinde muscles (three of which come from the Huckle-bone, but the other from the commissure of the Share-bone) the Right, the two *Vastæ*, the *Crureus* or Legge-muscle, and the *Popliteus*, or Ham-muscle. These seated in the leg for the use of the foote and toes are three fore and sixe hinde muscles: two of the fore bend the foote, one of which is called the *Tibialis anticus*, the other *Peroneus*, which you may divide into two. The third the bender of the toes, although it also partly bend the foote, to which also the bender of the Thumbe may be revoked. One of the hinde is the Toe-bender, others extend the foote, and are in this order; Two twins, one *Plantaris*, one *Soleus*, one *Tibialis posticus* and the great bender of the Toes, to which may be revoked the bender of the Thumbe. Of the sixteene seated in the foote, one is above, seated on the backe of the foote, which wee call the *Abductor* of the Toes; another in the sole of the foote, to wit, the litle bender of the Toes, which goes to the second joynte of the Toes alongst the inside of the foote; the other lends his helpe to the great Toe, which you may call the *Abductor* of the Thumbe; another is seated on the outside for the use of the litle Toe. To these are added the foure *Lumbrici*, besides the eight *Interosses*; or if you had rather, ten. And thus much may suffice for the enumeration of the muscles.

The Figure of the Muscles when the skin with its veines, the fat, and all the fleshy membrane are taken away, that part of the fleshy membrane encreased, which takes upon it the nature of a muscle, and is as being conjoynd with the muscles.

a, the muscle of the forehead.

b, the temporall muscle.

c, the muscle shutting the eye-lid.

d, the muscle opening the wings of the nose.

e, the fore part of the yoke-bone.

f, the muscle of the upper lip tending to the nose.

g, the beginning of the masseter or grinding muscle.

h, the broad muscle consisting of a fleshy membrane.

i, k, the beginning thereof which rises immediatly from the collar-bone & the top of the shoulder.

l, that part thereof which bends forwards to *l*.

m, the muscle which lifts up the arme.

n, the pectorall muscle.

o, the membranous part of this muscle which is joyned to the

nervous part of the first muscle of the *Abdomen* or belly. *q, q*, the fleshy portion thereof, from the 6. and 7. ribs, and the insertion thereof. *r* the muscle drawing down the arme. *s*, the oblique descending muscle of the lower belly. *t, t, t*, the insertion of the greater saw muscle. *u, u*, the *linea alba* or white line, at which the two oblique descendent muscles meet, covering the whole belly. *x*, the yard, the skinned being taken away. *y*, the vessels of seed. *z*, the testicles wrapped in the fleshy membrane. *a*, the fore muscle bending the cubite. *γ, γ*, the hinde muscle bending the cubite. *δ*, the muscle extending the cubite. *ε*, the two-headed muscle extending the wrest. *ς*, the muscle producing the broad tendon on the backe of the hand. *ζ*, his tendon. *η*, the muscle turning up the *W* and. *θ*, the upper muscle flattening the *W* and. *ι*, the second of the arme-benders, whose beginning is *κ*, and tendon *λ*. *ο*, a portion of the muscle, whereof one part yeelds tendons to the wrest, the other to the thumb. *π*, the fleshlesse articulation of the thumb. *ρ*, a muscle inserted into the wrest, lying neere to the following muscle. *σ*, a muscle divided into two tendons, the one whereof is inserted into the first joint of the thumb, the other into the following. *τ*, the first muscle of the thigh, whose head is at *υ*, and tendon at *φ*, and insertion at *χ*. *ψ*, the end of the second muscle of the thigh. *ω*, the end of the third muscle of the thigh. *1*, the sixt muscle of the legge; his beginning at *2*. almost wholly membranous at *3*. *4*, the ninth muscle of the legge. *5*, the eight of the legge. *6*, a portion of the sixth and seventh of the thigh. *7*, the Glandules of the groines. *8*, the eight of the thigh. *9*, the

9, the second of the legge. 11, the innermost of the ankle. 12, the sixth muscle of the foote, his originall 13. end 14. 15, the seventh of the foote. 16, the tendon of the muscle lifting up the great toe. 17, the muscles extending the foure other toes. 18, the abductor of the great toe. 19, a transverse ligament. 20, a tendon of the ninth muscle of the foote. 21, the first muscle. 22, the fourth muscle of the foote. 23, the tendon of the third muscle. 24, a muscle bending the third bone of the foure lesser toes.

THE SEVENTH BOOK Of Tumours against Nature in Generall.

CHAP. I.

*What a Tumor against Nature, vulgarly called an Impostume, is,
and what be the differences thereof.*

AN Impostume, commonly so called, is an affect against nature, composed and made of three kinds of diseases, Distemperature, ill Conformation, and Solution of Continuitie, concurring to the hindering or hurting of the Action. An humor, or any other matter, answering in proportion to a humor, abolishing, weakening, or depraving of the office or function of that part or body in

What an Impostume vulgarly so called is. The materiall causes of Impostumes, or unnaturall tumors.

which it resides, causeth it.

The differences of Impostumes are commonly drawne from five things; quantitie, matter, accidents, the nature of the part, which they affect or possesse; and lastly, their efficient causes. I have thought good for the better understanding of them, to describe them in this following Scheme.

A Table of the differences of Tumors.

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--|---|--------------------------|---|---|---|--|--|---|----|---|-------------|---|---|--------|--|--|---|----------------------|---|---|-----------------------|--|-------------------------|---|--------------------------|---|--|--|
| from their quantity, by reason whereof <i>Impostumos</i> are called -- | { Great, which are comprehended under the generall name of Phlegmons, which happen in the fleshy parts, by <i>Galen, Lib de tumor. contranaturam, & lib. 2. ad Glauconem.</i> Indifferent, or of the middle sort, as Fellons. Small, as those which <i>Avicen</i> calls <i>Bothores</i> , i. Pushes and Pustules, all kinde of Scabs and Leprosies, and lastly, all small breakings out. | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| from their accidents, as | { Colour, from whence <i>Impostumes</i> are named white, red, pale, yellow, blew, or blacke, and so of any other colour. Paine, hardnesse, softnesse, and such like, from whence they are said to be painefull, not painefull, hard, soft, and so of the rest. | | | | | | | | | | | | | | | | | | | | | | | | | | | |

From the condition and nature of the parts which they possesse, from whence the *Ophthalmia*, is a Phlegmon of the eyes. *Parotis* a tumor neere the eares. *Paronychia* or a whitlow at the roots of the nailes; and so of the rest.

From the efficient causes, or rather the manner of doing. For some impostumes are said to be made by defluxions, others by congestion, those are commonly hot, & the other commonly cold, as it shall more manifestly appeare by the following chapter.

CHAP.

CHAP. II.

Of the generall causes of Tumors.

After what
manner tu-
mours against
nature are
chiefely made,

Here are two generall causes of Impostumes, Fluxion, and Congestion. Defluxions are occasioned, either by the part sending, or receiving; the part sending discharges it selfe of the humors, because the expulsive facultie resident in that part is provoked to expell them, moved thereto, either by the troublesomenesse of their quantity or quality. The part receiving drawes, and receives occasion of heat, paine, weakenesse (whether naturall, or accidentall) opennesse of the passages, and lower situation.

Three causes
of heat.

The causes of heat, in what part soever it be, are commonly three, as all immoderate motion (under which frictions are also contained,) externall heat, either from fire, or sun, and the use of acride meates and medicines.

Foure causes
of paine.

The causes of paine are foure, the first, is a sodaine and violent invasion of some untemperate thing, by meanes of the foure first qualities; the second is solation of continuitie, by a wound, luxation, fracture, contusion or distention; the third, is the exquisit sense of the part, for you feele no paine in cutting a bone, or exposing it to cold or heate; the fourth is, the attention, as it were of the animall faculty, for the minde diverted from the actuall cause of paine, is lesse troubled, or sensible of it.

Two causes of
weakenesse.

A part is weake, either by its nature, or by some accident; by its nature as the Glandules and the Emunctories of the principall parts; by accident, as if some distemper, bitter paine, or great defluxion have seized upon it, and wearied it, for so the strength is weakened, and the passages dilated. And the lownesse of site yeelds opportunity for the falling downe of humors.

Two causes
of congestion.

The causes of congestion are two principally, as the weakenesse of the concoctive facultie, which resides in the part, (by which the assimilation into the substance of the part of the nourishment flowing to it is frustrated) and the weakenesse of the expulsive faculty; for whilst the part cannot expell superfluities, their quantity continually encreases.

And thus oftentimes cold impostumes have their originall from a grosse and tough humor, and so are more difficult to cure.

Lastly, all the causes of Impostumes may be reduced to three, that is, the primitive, or externall; the antecedent, or internall; and the conjuncte, or containing, as we will hereafter treat more at large.

CHAP. III.

The signes of Impostumes or Tumors in generall.

The principall
signes of tu-
mors are
drawne from
the essence of
the part,

Efore wee undertake the cure of Tumors, it is expedient to know their kindes and differences, which knowledge must be drawne from their proper signes, the same way, as in other diseases. But because the proper and principall signes of tumors are drawne from the essence of the part they possesse, we must first know the parts, and then consider what their essence and composition are.

We are taught both, by skill in Anatomy, and the observation of the deprived function, especially when the affected part is one of those which lie hid in the body; for we know whether or no, the externall parts are affected with a tumor against nature, by comparing that with his naturall which is contrary. For comparing the sound part with the diseased, wee shall easily judge whether it be swollen, or no.

But because it is not sufficient for a Chirurgien onely to know these generall signes (which

(which are knowne even to the vulgar) he must attentively observe such as are more proper and nere. And these are drawne from the difference of the matter and humors of which the tumors consist.

For this *Galen* teaches, that all differences of tumors arise from the nature and condition of the matter which flowes downe and generates the tumor; also they are knowne by such accidents as happen to them, as colour, heat, hardnesse, softnesse, paine, tension, resistance.

Wherefore paine, heate, rednesse, and tension indicate a sanguine humor; coldnesse, softnesse, and no great paine, phlegme; tension, hardnesse, the livide colour of the part, and a pricking paine by fits, melancholy; and yellowish and pale colour, biting paine without hardnesse of the part, choler.

And besides, Impostumes have their periods and exacerbations following the nature and motion of the humors of which they are generated. Wherefore by the motion and fits it will be no difficult matter to know the kinde of the humor; for as in the Spring, so in the morning the blood is in motion; as in the Summer, so in the middest of the day, choler; as in Autumne, so in the evening, melancholy; as in Winter, so on the night the exacerbations of phlegme are most predominante. For *Hippocrates* and *Galen* teach, that the yeare hath circuits of diseases, so that the same proportion of the excesse and motion of humors which is in the foure seasons of the yeare, is also in the foure quarters of each day.

Impostumes which are curable have foure times, their beginning, increase, state, and declination, and we must alter our medicines, according to the varietie of these times. We know the beginning by the first swelling, of the part; The increase when the swelling, paine, and other accidents do manifestly encrease, and enlarge themselves; the state, when the foresaid symptoms increase no more, but each of them, because at their height, remaine in their state immoveable, unlesse the very matter of the tumor degenerate, and change it selfe into another kinde of humor; The declination, when the swelling, paine, feaver, restlesnesse are lessened. And from hence the Chirurgion may presage what the end of the tumor may be; for tumors are commonly terminated foure manner of wayes, if so be that the motion of the humors causing them be not intercepted, or they without some manifest cause, doe flow backe into the body.

Therefore first they are terminated by insensible transpiration, or resolution; secondly, by suppuration when the matter is digested and ripened; thirdly, by induration when it degenerates into a Scyrrhus, the thinner part of the humor being dissolved; the fourth, which is the worst of all, by a corruption and Gangrene of the part, which is, when overcome with the violence, or the abundance or quality of the humor, or both, it comes to that distemper, that it looses its proper action.

It is best to terminate a tumor by resolution; and the worst by corruption; suppuration and induration are betwene both, although that is far better than this. The signes by which the Chirurgions may presage that an Impostume may be terminated by resolving, are the remission, or slackening of the swelling, paine, pulsation, tension, heat, and all other accidents, and the unaccustomed liveness and itching of the part; and hot Impostumes are commonly thus terminated, because the hot humor is easily resolved, by reason of its subtilty.

Signes of suppuration are the intensification or encrease of paine, heat, swelling, pulsation, and the feaver; for according to *Hippocrates*, paine and the feaver are greater when the matter is suppurating, then when it is suppurated.

The Chirurgion must be very attentive to know and observe when suppuration is made; for the purulent matter oft times lies hid (as *Hippocrates* saith) by reason of the thicknesse of the part lying above, or over it.

The signes of an Impostume degenerating into a Scyrrhus hardnesse, are the diminution of the tumor, and hardnesse remaining in the part. The causes of the hardnesse not going away with the swelling, are the weakenesse of nature, the grosnesse and toughnesse of the humor, and unskilfulnesse of the Chirurgion, who by too long using resolving things hath occasioned, that the more subtile part of the humor being dissolved, the rest of the grosser nature like earthy dreggs remains concrete in the part.

part. For so potters vessels dried in the Sunne grow hard. But the unskillfull Chirurgion may occasion a Scyrrhous hardnesse by another meanes, as by condensating the skinne, and incrassating the humors by too much use of repercussives. But you may perceive an Impostume to degenerate into a Gangrene thus, if the accidents of heat, rednesse, pulsation and tension shall be more intense, than they are wont to be in supuration; if the paine presently cease without any manifest cause, if the part waxe livide or blacke; and lastly, if it stinke.

Of disappea-
rance of a tu-
mor, and the
signes thereof.

But we shall treat of this more at large when we come to treat of the Gangrene and *Sphacelus*. A sodaine diminution of the tumor, and that without manifest cause, is a signe of the matter fallen backe, and turned into the body againe, which may be occasioned by the immoderate use of refrigerating thinge. And sometimes much flatulencie mixed with the matter, although there be no fault in those things which were applied.

Feavers and many other maligne Symptomes, as swooundings and convulsion, by translation of the matter to the noble parts, follow this flowing backe of the humor into the body.

CHAP. IIII.

Of the Prognosticks in Impostumes.

Cold tumors
require a lon-
ger cure.

Tumors arising from a melancholy, phlegmaticke, grosse, tough, or viscous humor, aske a longer time for their cure, than those which are of blood or choler. And they are more difficultly cured which are of humors not naturall, than those which are of humors yet contained in the bounds of nature.

Tumors made
of matter not
naturall, are
more difficul-
ty cured.

For those humors which are rebellious, offend rather in qualitie, than in quantitie, and undergoe the divers formes of things dissenting from nature, which are joyned by no similitude or affinitie with things naturall, as suet, poultis, hony, the dregs of oile, and wine; yea, and of solid bodies, as stone, sand, coale, strawes, and sometimes of living things, as Wormes, Serpents, and the like monsters.

Hippo. Aph. 8.
sect. 6.

The tumors which possesse the inner parts, and noble entrailles, are more dangerous and deadly, as also those which are in the joints, or neere to them. And these tumors which seaze upon great vessels, as veines, arteries, and nerves, for feare of great effusion of blood, wasting of the spirits and convulsion. So impostumes of a monstrous bignesse are often deadly, by reason of the great resolution of the spirits caused by their opening. Those which degenerate into a *Scyrrhus* are of long continuance and hard to cure, as also those which are in hydropicke, leprous, scabby and corrupt bodies, for they often turne into maligne and ill conditioned vulcers.

CHAP. V.

Of the generall cure of Tumors against Nature.

What must be
considered in
undertaking
the cure of tu-
mors.

Here be three things to be observed in cure of impostumes. The first is the essence thereof; the second the quality of the humor causing the impostume; the third the temper of the part affected. The first indication drawne from the essence, that is, from the greatnesse, or smallnesse of the tumor, varies the manner of curing, for the medicines must be increased or diminished according to the greatnesse of the tumor. The second, taken from the nature of the humor also changes our counsell, for a *Phlegmon* must be otherwise cured than an *Erysipelas* and an *Oedema* than a *Scyrrhus*, and a simple tumor, otherwise than a compound. And also you must cure after another manner a tumor comming of an humor not naturall, than that which is of a naturall humor, and otherwise that which is made by con-
gestion,

gestion, than that which is made by defluxion. The third Indication is taken from the part in which the tumor resides; by the nature of the part we understand its temperature, conformation, site, faculty, and function.

What we must understand by the nature of the part.

The temperature indicates that some medicines are convenient for the fleshy parts, as those which are more moist; others for the nervous, as more drie; for you must apply some things to the eye, and others to the throat; one sort of things to these parts which by reason of their raritie are easily subject to defluxion, another to those parts which by their density are not obnoxious to it.

But we must have good regard to the site of the part, as if it have any connexion with the great vessels, and if it be fit to powre forth the matter and humor when it is suppurated.

Galen by the name of faculty understands the use and sense of the part. This hath a manifold indication in curing, for some parts are principall, as the Braine, Heart, and Liver; for their vertue is communicated to the whole body, by the nerves, arteries, and veines.

What we must understand by the faculty of the part.

Others truly are not principall, but yet so necessary that none can live without them, as the Stomacke. Some are endued with a most quicke sence, as the eye, the membranes, nerves, and tendons; wherefore they cannot endure acrid and biting medicines. Having called to minde these indications, the indication will be perfected by these three following intentions, as if we consider the humor flowing downe, or which is ready to flow; the conjunct matter, that is, the humor impacted in the part; the correction of accidents; yet so that we alwayes have care of that which is most urgent and of the cause. Therefore first repercussives must be applied for the antecedent matter, strong or weak, having regard to the tumor as it is then, only excepting sixe conditions of Tumors; the first is, if the matter of the Tumor be venenate: the second, if it be a criticall abscesse: the third, if the defluxion be neare the noble parts: the fourth, if the matter be grosse, rough, and viscid: the fifth, when the matter lies farre in, that is, flowes by the veines which lies more deepe: the sixth, when it lies in the Glandes. But if the whole body be plethoricke, a convenient diet, purging, and Phlebotomie must be appointed, frictions and bathes must be used. Ill humors are amended by diet and purging. If the weaknesse of the part receiving draw on a defluxion, it must be strengthened.

What we must consider in performing the cure.

What things dissuade us from using repercussives.

If the part be inferiour in its site, let the patient be so seated, or layed, that the part receiving, as much as may be, may be the higher. If paine be the cause of defluxion, we must asswage it by things mitigating it. If the thinnesse, or lightnesse of the humor cause defluxion, it must be inspissate by meats and medicines. But for the matter contained in the part, because it is against nature, it requires to be evacuate by resolving things, as Cataplasmes, ointments, fomentations, cupping glasses; or by evacuation, as by scarifying, or by suppurating things, as by ripening and opening the Impostume. Lastly, for the conjunct accidents, as the Fever, paine and such like, they must be mitigated by asswaging, mollifying and malaxing medicines, as I shall shew more at large hereafter.

CHAP. VI.

Of the foure principall and generall Tumors, and of other Impostumes which may be reduced to them.

The principall and cheife Tumors which the abundance of humors generate are foure, A *Phlegmon*, *Erysipelas*, *Oedema* and *Scyrrhus*: innumerable others may be reduced to these, distinguished by divers names according to the various condition of the efficient cause and parts receiving. Wherefore a *Phygethlum*, *Phyma*, *Fellon*, *Carbuncle*, inflammation of the eyes, *Squincy*, *Bubo*,

What tumors may be reduced to a Phlegmon.

& lastly all sorts of hot and moist tumors may be reduced to a Phlegmon. The *Herpes miliaris*, the eating *Herpes*, Ringwormes and Tettors and all impostumes brought forth

Which to an Erysipelas.

Which to an
Oedema.

forth by choler, are contained under an *Erysipelas*. *Atheromata*, *Steatomata*, *Melicerides*, the *Testudo*, or *Talpa*, *Ganglion*, Knots, Kings-evill, Wens, watery Ruptures, the *Ascites* and *Leucophlegmatia* may be reduced to an *Oedema*, as also all flatulent tumors, which the abundance of corrupt Phlegme produces.

Which to a
Scyrrhus.

In the kindred of the *Scyrrhus* are reckoned a Cancer, Leprosie, Warts, Corns, a *Thymus*, a *Varix*, *Morphew*, black and white, and other Impostumes arising from a melancholy humor.

Now wee will treat of these Tumors in particular beginning with a Phlegmon.

CHAP. VII.

Of a Phlegmon.

What a true
Phlegmon is.

 Phlegmon is a generall name for all Impostumes, which the abundance of inflamed blood produces. That is called a true Phlegmon, which is made of laudable blood, offending onely in quantity. But a bastard Phlegmon, or a Phlegmonous Impostume hath some other, and proper name; as a Carbuncle, Fel-lon, Gangrene, Sphacel, and the like malignant Pustules. So when there is a conflux of diverse humor into one tumor, divers kinds of phlegmonous Impostumes called by diverse names, according to the more abundant humor, arise; as if a small portion of phlegme shall be mixed with a greater quantity of blood, it shall be called an *Oedematous Phlegmon*; but if on the contrary, the quantity of phlegme be the greater, it shall be named a phlegmonous *Oedema*, and so of the rest; alwayes naming the tumor, from that which is most predominant in it.

A Phlegmon,
one thing, and
a Phlegmo-
nous tumor
another.

Therefore we must observe that all differences of such tumors arise from that, either because the blood causing it offends onely in quantity; which if it doe, it causes that tumor which is properly called a Phlegmon; if in quality, it makes a Phlegmonous tumor, because the matter thereof is much departed from the goodnesse of blood.

But blood is said to offend in quantity, either by admixture of some other matter, as Phlegme, Choler, or melancholy, from whence proceedes *Oedematous*, *Erysipelous* and *Scyrrhus* Phlegmons; or by corruption of its proper substance from whence Carbuncles, and all kindes of Gangrens; or by concretion, and when nature is disappointed of its attempted and hoped for suppuration, either by default of the aire, or patient, or by the error of the physition; and hence oft times happen *Atheroma's*, *Steatoma's*, and *Melicerides*. Although these things be set downe by the ancients, of the simple and simular matter of the true Phlegmon; yet you must know, that in truth there is no impostume, whose matter exquisitely shewes the nature of one, and that simple humor without all admixture of any other matter; for all humors are mixed together with the blood, yet from the plenty of blood predominating, they are called Sanguine, as if they were of blood alone.

Wherefore if any Tumors resemble the nature of one simple humor, truly they are not of any naturall humor, but from some humor which is corrupt, vitiated and offending in quality; for so blood by adustion degenerates into choler and melancholy.

Gal. lib. de tu-
moribus, & 2.
ad Glanc.

Therefore a true Phlegmon is defined by *Galen*; A tumor against nature, of laudable blood flowing into any part in too great a quantity.

This tumor though most commonly it be in the flesh, yet sometimes it happens in the bones, as *Hippocrates* and *Galen* witnesse.

Hippoc. lib.
de vuln:
cap. Gal. lib. de
tumor. præter
naturam.

A phlegmon is made and generated thus, when blood flowes into any part, in too great a quantity; first the greater veines and arteries of the affected part are filled, then the middle, & lastly, the smallest and capillary; so from those thus distended, the blood sweats out of the pores and smal passages like dew; and with this the void spaces which are between the simular parts are first filled, & then with the same blood all the adjacent

adjacent parts are filled, but especially the flesh, as that which is most fit to receive defluxions, by reason of the spongiouse rarity of its substance; but then the nerves, tendons, membranes, and ligaments, are likewise stuffed full; whereupon a Tumor must necessarily follow, by reason of the repletion which exceeds the bounds of nature; and from hence also are tension and resistance; and paine also happens at the same time, both by reason of the tension and preternaturall heate.

And there is a manifest pulsation in the part, specially whilest it suppurates; because the veines, arteries, and nerves, are much pained, being they are not onely heated within by the influx of the fervide humor, but pressed without by the adjacent parts. Therefore seeing the paine comes to all the foresaid parts because they are too immoderately heated and pressed, the arteries which are in the perpetuall motion of their *Systole & diastole*, whilest they are dilated, strike upon the other inflamed parts, whereupon proceeds that beating paine.

The cause of a beating paine in a Phlegmon

Hereunto adde, the Arteries then filled with more copious and hot blood, have greater neede to seeke refrigeration by drawing in the encompassing Aire; wherefore they must, as of necessitie, have a conflict with the neighbouring parts which are swollen and pained. Therefore from hence is that pulsation in a Phlegmon which is defined by *Galen*, an agitation of the arteries, painefull, and sensible to the Patient himselve; for otherwise as long as we are in health, we doe not perceive the pulsation of the arteries.

Comm. ad Aph. 21. sect. 7.

Wherefore these two causes of pulsation, or a pulsifick paine in a phlegmon are worthy to be observed, that is, the heate and abundance of blood, contained in the vessels and arteries (which more frequently than their wont incite the arteries to motion, that is, to their *Systole* and *Diastole*) and the compression and streightning of the said arteries, by reason of the repletion and distention of the adjacent parts, by whose occasion the parts afflicted and beaten by the trembling and frequent pulsation of arteries are in paine.

Hence they commonly say, that in the part affected with a Phlegmon, they feele as it were the sense or stroke of a Mallet or Hammer smiting upon it. But also besides this pulsation of the arteries, there is, as it were another pulsation with itching from the humors whilst they putrefie and suppurate, by the permixtion, motion, and agitation of vapours thereupon arising.

Another kinde of Pulsation in a phlegmon.

The cause of heate in a Phlegmon is blood, which whilest it flowes more plentifully into the part, is as it were troden or thrust downe, and causes obstruction, from whence necessarily followes a prohibition of transpiration, and a putrifaction of the blood, by reason of the preternaturall heate. But the Phlegmon lookes red by reason of the blood contained in it, because the humor predominant in the part shines through the skinn.

CHAP. VIII.

Of the causes and signes of a Phlegmon.

THe causes of a Phlegmon are of three kindes; for some are primitive, some antecedent, and some conjunct. Primitive are falls, contusions, straines, immoderate labour, frictions, application of acrid ointments, burnings, long staying or labouring in the hot Sun, a diet unconsiderate, and which breeds much blood. The antecedent causes are, the great abundance of blood, too plentifully flowing in the veines. The conjunct, the collection or gathering together of blood impacted in any part.

The primitive causes of a Phlegmon.

The Antecedent and conjunct. The signes of a Phlegmon.

The signes of a Phlegmon are swelling, tension, resistance, feaverish heate, paine, pulsation, (especially while it suppurates) rednesse, and others, by which the abundance of blood is signified.

And a little Phlegmon is often terminated by resolution; but a great one by supuration; and sometimes it ends in a Scyrrhus, or a Tumor like a Scyrrhus; but

otherwhile

otherwhiles in a Gangren, that is, when the facultie, and native strength of the part affected, is overwhelmed by the greatnesse of the defluxion, as it is reported by Gal. l. de Tum. Galen. The Chirurgion ought to consider all these things, that he may apply and vary such medicines as are convenient for the nature of the Patient, and for the time and condition of the part affected.

CHAP. IX.

Of the cure of a true Phlegmon.

What kinde
of diet must be
prescribed in a
Plegmon,

He Chirurgion in the cure of a true Phlegmon must propose to himselfe foure intentions. The first of Diet; This, because the Plegmon is a hot affect and causes a feaver, must be ordained of refrigerative and humecting things, with the convenient use of the fixe things not naturall, that is, aire, meat, and drinke, motion and rest, sleepe and waking, repletion, and inanition; and lastly, the passions of the minde. Therefore let him make choise of that aire which is pure and cleere, not too moist, for feare of defluxion, but somewhat coole; let him command meates which are moderately coole and moist, shunning such as generate blood too plentifully; such will be brothes not too fat, seasoned with a little Borage, Lettuce, Sorrell, and Succory, let him be forbidden the use of all spices, and also of Garlicke, and Onions, and all things which heate the blood, as are all fatty and sweet things, as those which easily take fire. Let the Patient drinke small wine, and much alaied with water: or if the feaver be vehement, the water of the decoction of Licoris, Barly, and sweet almonds, or water and sugar; alwayes having regard to the strength, age, and custome of the Patient.

For if he be of that age, or have soled his life, that he cannot want the use of wine, let him use it, but altogether moderately. Rest must be commanded; for all bodies waxe hot by motion, but let him chiefly have a care that hee doe not exercise the part possessed by the plegmon for feare of a new defluxion. Let his sleepe be moderate, neither, if he have a full body, let him sleepe by day, specially presently after meate. Let him have his belly soluble, if not by nature, then by art, as by the frequent use of glisters and suppositories. Let him avoid all vehement perturbations of minde, as hate, anger, brawling; let him wholly abstaine from venery.

How to divert
the defluxion
of humors.

This manner of diet thus prescribed, wee must come to the second scope, that is, the diversion of the defluxion, which is performed by taking away its cause, that is, the fulnesse and illnesse of the humors. Both which we may amend by purging and blood-letting, if the strength and age of the patient permit.

The paine
must be asswa-
ged.

But if the part receiving be weake, it must be strengthened with those things which by their astringent amend the opennesse of the passages, the violence of the humor being drawne away by cupping glasses, frictions, ligatures. But if paine trouble the part, which is often the occasion of defluxion, it must be mitigated by medicines asswaging paine.

When we must
use repercussives.

The third scope is to overcome the conjunct cause. That we may attaine to this, we must enter into the consideration of the tumor, according to its times, that is, the beginning, encrease, state, and declination. For from hence the indications of variety of medicines must be drawne. For in the beginning we use repercussives to drive away the matter of the Phlegmon flowing downe, as the white of an Egge, Oxierate, the juices or waters of Houfelecke, Plantaine, Roses; Cataplasmes of Henbane, Pomgranate, Pills, Balausties, Bolearmenicke, Terra sigillata, oile of Roses, Quinces, Mirilles, Poppies.

Of these simples, variety of compound medicines arises. This may be the forme, of a Cataplasme. R, *far. bordei* ℥ij. *succi sempervivi*, *plantag. an.* ℥iij. *pul. malicorij*, *balaustrorum & rosar. an.* ℥ij *ol. mirtill. & rosar. an.* ℥j, *fiat Cataplasma.* Another, R, *Plantag. solani*, *hyoscyam. an. m. ij.* *cauda equin. tapsi barb. cintonodie an. m. j.* *coquantur perfecte in oxierato, pistentur, trañciantur, addendo pulveris mirtill. nuc. cupressi. & ros. rub. an.* ℥iij, *farin. fab. ℥ij*, *olei rosar. & cydon. an.* ℥iij: mixe

mixe them and make a cataplasma to the forme of a liquid pultis. And you may use this liniment, by dipping linnen clothes in it, and applying to the part; R, *ol. nymph. & rosar. an. ʒiij, aq. ros. solani & plantag. an. ʒij, aceti ʒiij, albumin. ovorum n. iij, fiat linimentum.* Also *ung. rosatum & ung. Album, camphor. Ras* are good to apply to it, as in like manner, *Emp. Diacalcitheos* dissolved in vinegar, and oile of Roses, and also *Populeon* may be used. In the increase you must have care of the humor flowing downe, and of that which already impacted in the part, did formerly fall down. Therefore repercussives must be tempered & mixed with discussive medicines, but so that they may carry the chiefe sway, as R, *fol. malva, absinth. plantag. an. m. iij, coquantur in oxicato, contundantur, trajectis adde farina fabarum & hordei an. ʒj, pul. rosar. rub. & Absinth. an. ʒi, ol. rosar. & chamem. an. ʒj, fiat cataplasma ad formam pultis satis liquida.* Another. R, *farina hord. ʒiij. farina sem. lini & fenugraci, an. ʒj. coquantur in aqua communi, addendo sub finem pul. mirtillorum, rosarum & chamemeli an. ʒʒ, axungia anseris & olei rosarum an. ʒj, misce, fiat cataplasma.*

What locall medicines we must use in the encrease.

But in the state the repercussives, & discussives ought to be alike with some anodine, or mitigating medicines, if it be painefull, as R, *rad. Althea ʒiij, malva, parietar. an. m. iij, coquantur sub cineribus, addendo farin. fabarum & lentium an ʒij, pulveris chamem. & meliloti an. ʒʒ. olei chamem. & rosar. an. ʒj. axungia gal. ʒij. fiat cataplasma.* Another R, *mica panis triticei aqua calida macerati ʒʒ, pulveris rosar. rub. & absinth. ana. ʒvj. olei aneth. & mellis com. an. ʒij. misce omnia simul & fiat cataplasma ad formam pultis satis liquida;* which is of chiefe use when there is paine.

What in the state,

But when the violence of paine and other symptomes are asswaged, it is likely that the plegmon is come to determination. Wherefore then we must use more powerfull and strong discussives, and onely then beginning with the more gentle, lest the subtiler part of the humor being dissolved, the grosser, remaining in the part, should grow hard, as R, *mal. bisnal. an. m. iij. coquantur addendo farina hordei ʒij, mellis com. ʒj, ol. chama. & melilot. an. ʒʒ, fiat cataplasma,* Or R, *radicum Brion. & Cucumer. agresti. an. ʒij, florum chamem. & melilot. ana. m. iij. coquantur in hydromelite addendo farina sem. lini & fenugrac. an. ʒij, ol. aneth. axungia Anser. & anat. an. ʒj. fiat Cataplasma.* And this plaister following may here finde place.

What in the declination

R, *Diachyl. mag. ʒij, Empl. de melilot. ʒj, olei aneth. & chamamel. an. ʒʒ:* dissolve them all together and make a medicine for your use. Or R, *Empl. de mucag. & oxycro: an. ʒij. Empl. Diachyl. Ireat. ʒj. olei liliorum & chamamel. quantum satis est,* and make thereof a soft emplaister.

The fourth scope of curing a Phlegmon consists in correction of the accidents which accompany it; of which paine is the principall.

The correction of the accidents,

Wherefore the Chirurgion must be diligent to asswage it, for besides, that it weakens the strength, and debilitates and depraves the function, it also causes defluxions by drawing the bloud and spirits to the part affected.

According to the varietie of paine there must be variety of medicines, as R, *mica panis albi in lacte tepido macerati ʒʒ, vitell. ovorum iij. ol. rosar. ʒij, croci ʒʒ, fiat cataplasma.* Or R, *florum chamem. & melil. an. p. iij. farina sem. lini. & fenugrac. an. ʒj. fiat cataplasma pultis satis liquida.* Or R, *mucagin. rad. althea & fenugraci an. ʒiij, ol. rosar. & aneth. an. ʒj. farin. sem. lini. quantum satis, ut inde formetur cataplasma satis molle.*

The discommodities of paine. Medicines asswaging paine.

But if the paine remaine, and yeeld not to these remedies, we must flie to stronger, making use of narcoticks, or stupifactives, but with care lest we benum, or dead the part; as R, *fol. hyoscyani & papaver. sub. cineribus coctorum an. ʒiij, adipis suilla & ol. ros. an. ʒj, croci. ʒij, fiat cataplasma:* or, R, *fol. cicuta & solani furiosi. an. ʒiij, coquantur sub cineribus, pistentur, & trajectantur addendo unguent. popul. & ol. rosar. an ʒj, farin. fenugrac. quantum satis erit, ut inde formetur cataplasma ad formam pultis liquida.*

Narcoticke medicines.

CHAP. X.

The cure of an ulcerated Phlegmon.

The signes
of a Phlegmon
turning to an
Abscess.

Vt it often happens, that the humor is so impact in the part, that it cannot be repressed, and so grosse, that it cannot be discussed; which we may know by the greatnesse of the heat and swelling, by the bitternesse of the pricking paine, the feaver, and pulsation, and heavinesse.

Lib. 2 ad
Glauc. Cap. 7.

Wherefore laying aside all hope of discussing, wee must come to suppuratives. For which purpose *Galen* fomentes the swollen part with water, or oile being warme, or with both of them; and then applies this following cataplasme.

Suppurative
medicines.

R^{re}, *farina triticea* vel *mica panis*, ℥iij. ol. com. ℥iij, aqua com. quantum sufficit, fiat cataplasma; or R^{re}, rad. *liliorum alb.* & *alibea*, an. ℥iij, fol. *malva*, *parietar.* & *senecionis ana.* m. j. coquantur in *hydromelite*, pissentur, trajectis adde *farin. sem. lini* ℥ij, *axungie suilla*, ol. *liliorum* an. ℥ss, fiat cataplasma: Or R^{re}, *malva*, *bismalva*, *violar.* an. m. j. *caricarum* ping. n. x. *passul.* ℥ij, coquantur in aq. com. tussis, & trajectis, adde *mellis* com. ℥ij, ung. *basilicon.* & *butyri recent.* ana. ℥j, fiat cataplasma. You may profitably use for the same purpose *Empl. Diachylon magnum*, or *Basilicon*. Or R^{re}, *Empl. Dyachil. mag.* ℥iij. ung. *basilicon.* ℥j, ol. *liliorum* ℥ss. Of these mixed together make a medicine for the foresaid use.

The signes of
pus or matter.

When the heat, paine, feaver, and other accidents shall remit, when the tumor hath a sharpe head, when by the pressing of your finger you finde the humor to flow as it were to and fro, then you may know that it is ripe.

Wherefore without any further delay the tumor must be opened, lest the matter too long shut up, corrode the adjacent parts, and the ulcer become sinuous and fistulous.

For this usually happens, especially then, when the matter is venenate or maligne, or when the swelling is neare a joint, or at the fundament, or such like hot and moist places.

Hip. lib. de
Fistula.

For by the decree of *Hippocrates* wee should anticipate the maturation of such tumors by opening.

They may be opened with an incision knife or causticke, and that, either actuall or potentiall. For if the patient shall be hartlesse and lesse confident, so that he either cannot, or will not endure any instrument, you must make way for the matter by a potentiall cautery. You may also doe the businesse by another slight, as thus.

Thrust the point of a sharpe knife or lancet, through a brasse counter that it may stand fast in the midst thereof; then cover it diligently with some Emplaister or Cataplasme, that neither the Patient nor standers by perceive the deceit: then laying on the plaister as that you would make a passage for the matter by that meanes, but when you have fitted the point to the part, where it is fit to open the tumor, so guide the Counter with your fingers, that you may presently make an impression into the Tumor, sufficient for excluding the matter. I have here expressed three deliniations of such Instruments, that you may use these, either bigger, lesser or indifferent, as occasion shall serve.

Counters with the points of Knives or Lances put
through them.

A. shewes the Counter or peece of Silver.
B. shewes the point of the Lancet.

Other Instruments for opening Abſceſſes.

Rings in which little knives lye hid,
fit for to open Abſceſſes.

The Deliniation of a Trunke or
hollow Inſtrument going
with a ſpring.

- A. Shewes the thicker pipe.
- B. Shewes another which enters and is faſtened in the other by a ſcrue.
- C. The point of the Inſtrument, looking out.
- D. The ſpring which forces the Inſtrument.

But there are ſeven things which muſt be diligently conſidered in opening all ſorts of Impoſtumes. The firſt is, that you put your knife to that part of the Abſceſſe which is the ſofter, and yeelds to the impreſſion of your fingers, and where it riſes into a head, or point. The ſecond is, that you make choiſe of that place for diſſection which is the loweſt, that ſo the contained impurity may the more readily flow out, and not ſtay in the paſſage. The third is, that it be made according to the wrinkles of the ſkin, and the right fibers of the Muſcles lying next under the ſkin. The fourth is, that you turne your knife from the larger veſſels and Nerves worth ſpeaking of. The fifth is, that the matter contained in them be not evacuated too abundantly at once in great Abſceſſes, leſt thereby the ſtrength be dejected, the ſpirits being much waſted together with the unprofitable humor. The ſixth is, that the affected part be handled as gently as you can. The ſeventh is, that after the opening when the matter is evacuated, the Abſceſſe be clenſed, filled with fleſh, and laſtly consolidated and cicatrized. But ſeeing that commonly after ſuch ſections ſome part of the Tumor remains, all the contained humor being not wholly ſuppurated, the Chiurgion may perceive that this is an implicate affect, that is a, Tumor and Ulcer. But the Cure thereof muſt be ſo, that you take away the Tumor before the ulcer; for the ulcer cannot be healed before the part be reſtored to its nature. Therefore the ſuppuratives formerly preſcribed muſt be uſed, and the ulcer muſt be dreſſed for two or three dayes with this following Medicine.

R. Vitellum unius ovi, terebinth. Venetæ, & ol. Roſar. an. ʒʒ, fiat medicamentum. Then you muſt ſeek to clenſe it by this following Medicine.

What the cure
muſt be after
the opening
of the Abſceſſe

Deterſive
Medicines.

R. Mellis

*Unguentum
de Appio.*

Rx Mellis rosar. ʒij, Syrupi rosar. & tereb. Venet. an. ʒijß, far. hordei ʒij, fiat medicamentum ad usum. For this very purpose there is a singular Deterfive made of *Appium* or *Smallage* of which this is the description.

Rx Succi appij, plantag. beton. an. ʒij, Mellis commun. ʒv, terebint. Venet. ʒiiij, farin. Hordei & Orobi, an. ʒij, pulveris Aloës, rad. Ireos florent. myrrha, an ʒj. coquatur melcum succis, quibus consumptis addantur farina & pulveres, & misceantur omnia ad formam unguenti. But if you would cleanse it more powerfully, you may use *Unguentum Apostolorum*; or *Unguentum Aureum* and *Egyptiacum* mixed according to the scope you conceive in your minds, when the ulcer shall seeme sufficiently cleansed, it shall be filled with flesh and cicatrized after the manner we shall declare in the proper treatise of the cure of *Ulcers*.

CHAP. XI.

Of feavers, and the cures of these feavers which accompany Plegmons.

The Feaver of
a Phlegmon.
What a Feaver
is-

AMongst the *Symptoms* which most usually accompany *Phlegmons*, & afflict all the body of the patient, *Feavers* are the cheife; that is hot, and dry distempers kindled in the heart, and thence by the *Artery* is sent over all the body; yet these which usually follow this kinde of *Tumors* are *Ephemera*, that is, *Diary*, unputrid *Synochi* or putrid *Synochi*; Of whose nature and order of cure I will here briefly relate what I have learnt from my Masters, that is, *Doctors of Physicke*, as I have beene conversant with them in the practise of my *Arte*.

What an
Ephemera, or
Diarye is,

The *Ephemera*, or *Diary* [that is of one day] is, a hote and dry distemperature kindled in the vitall spirits. It hath that name, because by its owne nature it carries not above the space of one day or twenty foure houres, by reason it is kindled in a subtile easily diffipable matter.

The causes
thereof,

The efficient causes of this Feaver are wearinesse, hunger, drunkenness, anger, fury, sorrow, watching, great and peircing cold, Aduersion, Bathes, and manner of living inclining more to heat than ordinary, applying, using or drinking of acride medicines as *Poysons*, or of hot meats, and drinckes; to conclude, all the efficient causes common to all Feavers, putrifaction onely excepted which properly appertaines to putride feavers.

*Aphorism. 55.
lib. 4.*

For a *Bubo* also, which is a *Phlegmon* of the *Glandules*, causes a *Diary*, as *Hippocrates* shewes. All feavers proceeding from the *Tumors* of the *Glandules* are evill, the *Diary* excepted. Which *Aphorisme* must be understood warily and with that distinction which *Galen* gives in his commentary, where he saith; It is only to be understood of *Tumors* risen in the *Glandules* without occasion, that is, without any evident and manifest cause; for otherwise Feavers that thence take their originall, though not *Diary*, yet are not all evill, as we learne by *Buboes* in *Children*, and the venereous *Buboes*, which happen without inflammation, or corruption of the liver, for such commonly have no malignant Feaver accompanying them, which thing is worthy a *Chirurgions* observation.

The signes of a
Diarye.

The common signes of a *Diary* are, a moderate and vaporous heate feeling gentle to the hand, a pulse swift and frequent, sometimes great and strong, as when the *Diary* is caused by anger; sometimes litle, if the Feaver proceede from sorrow, hunger, cold, crudity; for other respects equall and ordinary.

Why in a *Diarye*
the vrines
like to these in
health.

The most certaine signes are, if the Feaver come upon one not by litle and litle but sodainly and that from some externall and evident cause, no loathing of meat, no causelesse wearinesse, no deepe sleepe, yawning, great paine, restlesnesse, shaking nor cold going before, and lastly no other troublesome symptome preceeding. Wee here make no mention of the urine, because most frequently they resemble the vrines of sound bodyes; for in so short a time as *Diaryes* endure, there cannot so great a perturbation be raised in the blood that there may be signes thereof found in the urine. A *Diary* is ended in one fit, which by the proper nature of this Feaver lasts but one day,

day, although sometimes, otherwise it is extended to three, or foure dayes space; and then it easily degenerates into a Putride, especially any error of the Patient, Philition, or those which attend him concurring therewith, or if the externall things bee not rightly fitted.

This Feaver is terminated either by insensible transpiration, or by the moisture of the skin, or by a sweate naturall, gentle, and not ill smelling; to this Diary wee may referre the unputride *Synochus*, generated of blood not putrid, but onely heated beyond measure. For usually there arises a great heate over all the body, by meanes of the blood immoderately heated; whence the veines become more tumide, the face appeares fiery, the Eyes red and burning, the breath hot, and to conclude, the whole habite of the body more full, by reason of that Ebullition of the blood, and the diffusion of the vapours thence arising over all the body: Whence it is, that this kinde of *Synochus* may be called, a vapourous Feaver. To this Children are incident as also all sanguine bodyes, which have no ill humors. The cure of this and the *Ephemera* or Diary is the same; because it may scarce seeme different from the *Ephemera* in any other thing, than that it may be prolonged for three or foure dayes. Wherefore whatsoever we shall say for the cure of the *Ephemera*, may be all applyed to the *Synochus*, bloodletting excepted, which in an unputrid *Synochus* is very necessary.

The unputride
Synochus,

Now the Cure of a Diary Feaver consists in the decent use of things not naturall, contrary to the cause of the disease; wherefore bathes of warme and naturall water are very profitable; so that the Patient be not Plethoricke, nor stufft with excrements, nor obnoxious to catarrhes and defluxions, because a catarrhe is easily caused and augmented by the humors diffused and dissolved by the heate of a bath; therefore in this case we must eschew frictions, and anointing with warme oile, which things notwithstanding are thought very usefull in these kind of Feavers, especially when they have their originall from extreme labour, by astriction of the skin or a *Bubo*. Let this be a generall rule, that to every cause, whence this Feaver proceeded, you oppose the contrary for a remedy; as to labour, rest; to watching, sleep; to anger and sorrow, the gratefull society of friends, and all things replenished with pleasant good will; and to a *Bubo*, the proper cure thereof.

The cure of a
Diary feavers

Wine moderately tempered with water according to the custome of the sicke patient, is good and profitable in all causes of this Feaver, except he be pained in his head, or that the Feaver drew its originall from anger, or a *Bubo*; for in this last case especially, the patient must abstaine wholly from wine, untill the inflammation come to the state, and begins to decline. This kinde of Feaver often troubles infants; and then you must prescribe such medicines to their Nurses, as if they were sicke, that so by this meanes their milke may become medicinable. Also it will be good to put the Infant himselfe into a bath of naturall and warme water, and presently after the bath to anoint the ridge of the backe and brest with oile of Violets. But if a *Pblegmon* possesse any inward part, or otherwise by its nature be great, or seated neare any principall Bowell, so that it may continually send from it either a putrid matter or exhalation to the heart, and not onely affect it by a quality or preternaturall heate by the continuity of the parts, thence will arise the Putride *Synochus*, if the blood by contagion putrifying in the greater vessells, consists of an equall mixture of the foure humors. This Feaver is chiefly thus knowne, it hath no exacerbations, or remissions, but much lesse intermissions; it is extended beyond the space of twenty foure houres, neither doth it then end in vomite, sweat, moisture, or by litle and litle by insensible transpiration, after the manner of intermitting Feavers, or Agues; but remains constant, untill it leaves the Patient for altogether; it commonly happens not unlesse to these of a good temper and complexion, which abound with much blood, and that tempered by an equall mixture of the foure humors. It commonly endures not long, because the blood by power of some peculiar putrifaction degenerating into choler or Melancholy, will presently bring forth another kinde of feaver, to wit a Tertian or continued Quartaine.

The use of
wine in a Dia-
rye,

How a put-
ride *Synochus*
is caused.

The cure of this Feaver (as I have heard of most learned Physitions) chiefly consists in Bloodletting. For by letting of blood the fullnesse is diminished, & therefore the obstruction is taken away, and lastly the putrefaction. And seeing that in this kinde of

Phlebotomy
necessary in a
putride *Synochus*

Feaver

Feaver there is not onely a fault of the matter, by the putrefaction of the blood, but also of the Temper by excesse of heat; certainly Phlebotomy helps not only, as we said, the putrefaction, but also the hote distemper. For the blood in which all the heate of the creature is contained, whilest it is taken way, the acrid and fuliginous excrements exhale and vanish away with it, which kept in, encreased the Feverish heate. Moreover, the veines, to shun emptinesse, which nature abhors, are filled with much cold aire in stead of the hot blood which was drawne away, which followes a cooling of the habite of the whole body; yea and many by meanes of Phlebotomy have their bellies loosed, and sweate, both which are much to be desired in this kinde of Feaver.

What benefit we may reape by drawing blood even to fainting.

This moved the ancient Physitions, to write, that we must draw blood in this disease, even to the fainting of the Patient.

Yet because thus, not a few have poured out their lives together with their blood, it will be better and safer to divide the evacuations, and draw so much blood at severall times, as the greatnesse of the disease shall require, and the strength of the Patient may beare.

Why we must give a clyster presently after blood-letting.

When you have drawne blood, forthwith inject an emollient and refrigerative clyster; lest that the veines emptied by Phlebotomy may draw into them the impurity of the Guts; but these clysters which coole too much, rather binder the belly, than loose it. The following day the Morbifick matter must be partly evacuated by a gentle purge, as a bole of *Cassia*, or *Catholicon*; then must you appoint Syrupes which have not onely a refrigerative quality, but also to resist putrefaction, such as the Syrupe of Lemmons, Berberries, of the Iujce of Citrons, of Pomgranats, Sorrell and Vineger; let his diet be absolutely cooling and humecting and also slender; for the native heate much debilitated by drawing of a great quantity of blood cannot equall a full diet. Therefore it shall suffice to feed the Patient with chicken and veale brothes made with cooling herbes, as Sorrell, Lettuce and Purslaine. Let his drinke be Barly water, Syrup of Violets mixed with some pretty quantity of boiled water, *Iulepum Alexandrinum*, especially if he be troubled with scouring, or laske. But the Physition must chiefly have regard to the fourth day, for if then there appeare any signes of concoction in the excrements, the *Crisis* must be expected on the seventh day and that either by a loosenesse of the belly, or an abundance of urine, by vomits, sweats, or bleeding. Therefore we must then doe nothing, but commit the whole businesse to nature.

When drinking of water is to be permittted in a putride Synochus.

But for drinking cold water, which is so much commended by *Galen* in this kinde of Feaver, it is not to be suffered before there appeare signes of concoction; moreover in the declining of the disease the use of wine will not be unprofitable to helpe forwards sweats.

CHAP. XII.

Of an Erysipelas, or Inflammation.

Having declared the cure of a Phlegmon, caused by laudable blood, we must now treat of these tumors which acknowledge Choler the materiall cause of their generation, by reason of that affinity which interceeds betweene Choler and Blood. Therefore the tumors caused by naturall Choler, are called *Erysipelata*, or Inflammations; these containe a great heate in them, which chiefly possesse the skin, as also oftentimes some portion of the flesh lying under it. For they are made by most thin and subtle blood (which upon any occasion of inflammation easily becomes cholericke) or by blood and choler, hotter than is requisite, and sometimes of choler mixed with an acride serous humor.

The definition of an Erysipelas.

Gal. Cap. 2. lib. 14. Meth. med. 2. ad Glau.

That which is made by sincere and pure choler, is called by *Galen*, a true and perfect *Erysipelas*. But there arise three differences of *Erysipelas* by the admixture of choler with the three other kinds of humors. For if it being predominant be mixed with blood, it shall be termed *Erysipelas Phlegmonodes*; if with phlegme, *Erysipelas œdematodes*; if with Melancholy, *Erysipelas Scirrhus*. So that the former and

and substantive word shewes the humor bearing dominion, but the latter or adjective that which is inferiour in mixture. But if they concur in equall quantity, there will be thereupon made *Erysipelas Phlegmone*; *Erysipelas cedema*; *Erysipelas scirrhus*.

Galen acknowledges two kinds of *Erysipelas*, one simple and without an ulcer, Two kinds of Erysipelas. the other ulcerated. For *Choler* drawne and severed from the warmnesse of the blood, running by its subtilty and acrimony vnto the skin, ulcerates it; but restrained by the gentle heat of the blood, as a bridle, it is hindred from peircing to the top of the skin, and makes a tumor without an ulcer. But of unnaturall *choler* are caused many other kinds of cholericke tumors, as the *Herpes excedens*, and *Miliaris*, and lastly all sorts of tumors which come betweene the *Herpes* and *Cancer*. You may know *Erysipelas* chiefly by three signes, as by their colour, which is a yellowish red; by their quicke sliding backe into the body at the least compression of the skin (the cause of which is the subtilty of the humor and the outward site of it under the skin, whereupon by some an *Erysipelas* is called a Disease of the skin) Lastly by the number of the Symptoms, as heat, pulsation, paine. The heat of an *Erysipelas* is far greater than that of a *Phlegmon*, but the pulsation is much lesse; for as the heat of the blood is not so great, as that of *choler*, so it farre exceeds *choler* in quantity and thicknesse, which may cause compression and obstruction of the adjacent muscle.

For *Choler* easily dissipable by reason of its subtilty quickly vanishes, neither doth it suffer it selfe to be long contained in the empty spaces betweene the muscles; neither doth an *Erysipelas* agree with a *Phlegmon* in the propriety of the paine. For that of an *Erysipelas* is pricking and biting without tension, or heavinesse, yet the primitive, antecedent and conjunct causes are alike of both the tumors. Although an *Erysipelas* may be incident to all parts, yet principally it assailes the face, by reason of the rarity of the skin of that place, and the lightnesse of the cholericke humor flying upwards. It is ill when an *Erysipelas* comes upon a wound, or ulcer, and although it may come to suppuration, yet it is not good; for it shewes that there is obstruction by the admixture of a grosse humor, whence there is some danger of erosion in the parts next under the skin. Gal. lib. 2. ad Glanc. Hip. Apbo. 79 Sed. 7. Aph. 25 Sed. 6. Aph. 43. Sed. 3.

It is good when an *Erysipelas* comes from within outwards; but ill when from without it retires inward. But if an *Erysipelas* possesse the wombe it is deadly, and in like manner if it spread too far over the face, by reason of the sympathy of the membranes of the braine.

CHAP. XIII.

Of the cure of an *Erysipelas*.

IN the cure of an *Erysipelas* we must procure two things, to wit, evacuation and Refrigeration. But because there is more need of cooling, than in a *Phlegmon*, the cheefe scope must be for refrigeration. Which being done, the contained matter must be taken away and evacuated with moderately resolving medicines. We must doe foure things to attaine unto these forementioned ends. First of all we must appoint a convenient manner of Diet, in the use of the sixe things not naturall; that is, we must incrassate, refrigerate and moisten as much as the nature of the disease and patient will suffer, much more than in a *Phlegmon*; then we will evacuate the Antecedent matter, by opening a veine, and by medicines purging *choler*. And that by cutting the Cephalicke veine, if there be a portion of the blood mixed with *Choler*, if the *Erysipelas* possesse the face, and if it be spread much over it.

But if it shall invade another part, although it shall proceed of pure *choler*, *Phlebotomy* will not be so necessary, because the blood which is as a bridle to the *choler* being taken away, there may be danger, lest it become more fierce; yet if the body be plethoricke, it will be expedient to let blood, because this, as *Galen* teacheth, is oft times the cause of an *Erysipelas*. It will be expedient to give a clyster of refrigerating and humecting things before you open a veine; but it belongs to a learned and prudent

Gal. 16. Method.

4 Things to be performed in curing an Erysipelas.

In what Erysipelas it is convenient to let blood, in what not.

What topicke medicines are fit to be used in the beginning of an *Erysipelas*

prudent Physition to prescribe medicines, purging choler.

The third care must be taken for Topicke, or locall medicines, which in the beginning and encrease must be cold and moist, without any either drynes or astringion, because the more acride matter by use of astringent things being driven in, would ulcerate and fret the adjacent particle.

Galen and *Avicen* much commend this kinde of remedy; Take faire water ℥vj. of the sharpest Vinegar ℥j, make an Oxycrate, in which you may wet linnen clothes and apply to the affected part and the circumjacent places, & renew them often. Or R, *Succi solani, plantag. & semper vivi, an. ℥ij, aceti ℥℥, Mucaginis sem. Psyllij ℥ij, succi hyoscyami ℥j, Misce.* But if the *Erysipelas* be upon the face, you must use the medicine following.

R. *Vaguent. Ros. ℥iiij, succi plantagin. & semper vivi, an. ℥j. trochisc. de Camphora ℥℥, aceti parum;* let them be mixed together and make a liniment. But if the heate and paine be intolerable, we must come to narcoticke medicines. As, R *succi hyoscyami, solani, cicuta, an. ℥j. album. ovorum n. ij. aceti ℥℥, opij & Camphor. an. gra. 4 croci ℥℥, Mucaginis sem. psill. & sanigr. extracta in aq. ros. & plantag. an. ℥j, ol. de papau. ℥ij. fiat linimentum, addendo ung. refrigerantis Gal. camphor q. satis sit.* Yet we must not use such like medicines too long, lest they cause an extinction of the native heate and mortification of the part.

What caution must be had in the use of narcoticke medicines.

Resolving and strengthening medicines.

Wherefore such Narcoticke medicines must be used with regard of place, time and such other circumstances. Therefore we may three manner of wayes understand when to desist from using Narcoticke or stupefactive medicines. The first is when the Patient in the affected part feels not so much heat, pricking and paine, as before; The second is when the part feels more gentle to the touch than before; The third when the fiery and pallide colour begins by litle and litle to waxe livid and blacke; for then must we abstaine from Narcoticke, and use resolving and strengthening things, whereby the part may be revived and strengthened by recalling the Native heate; As R. *Farina hordei & Orobi, an. ℥ij farina sem. lini ℥j℥. coquantur in Hydromelite vel oxycrato, addendo pulv. rosarum & chamemal. an. ℥℥. ol. anethi & chamem. an. ℥j, fiat cataplasma.* Or you may use this following fomentation R. *Rad. Althea ℥ij, sol. malva, bis mal. pariet. al. sinthij, salvia, an. m. j. flor. chamem. meliloti, rosar. rub. an. m. ij. coquantur in aquis partibus vini & aqua, & fiat fons cum spongia.* After the fomentation you may apply an Emplaster of *Diachylon treatum*, or *Diapalma* dissolved in oile of chamomille and Melilote, and such other like. The fourth Intention which is of the correction of accidents, we will performe by these meanes which we mentioned in curing a Phlegmon, by varying the medications, according to the judgement of him which undertakes the cure.

CHAP. XIII.

Of the Herpes; that is Teaters, or Ringwormes, or such like.

What a Herpes is, what be the kinds thereof.

Gal. 2. ad Glauconem.

What the Herpes miliaris is. What the exedens.

Erpes is a tumor caused by pure choler separated from the rest of the humors, that is carryed by its naturall lightnesse and tenuitye even to the outer or scarfe skin, and is diffused over the surface thereof. *Galen* makes three sorts of this tumor. For if perfect choler of an indifferent substance, that is, not very thicke, cause this tumor, then the simple *Herpes* is generated, obtaining the name of the Genus; but if the humor be not so thin, but compounded with some small mixture of Phlegme, it will raise litle blisters over the skin like to the seeds of Millet, whence it was that the Ancients called this Tumor the *Herpes Miliaris*. But if it have any admixture of Melancholy, it will be an *Herpes exedens*, terrible by reason of the erosion or eating into the skin and muscles lying under it.

Three intentions in curing Herpes.

There are absolutely three intentions of curing; The first is to appointe a Diet just like that we mentioned in the cure of an *Erysipelas*; The second is to evacuate the antecedent cause, by medicines purging the peccant humor, for which purpose oftentimes

times clysters will suffice, especially if the patient be somewhat easie by nature, and if the urine flow according to your desire; for by this a great part of the humor may be carryed into the bladder; The third shall be to take away the conjunct cause by locall medicines ordained for the swelling and ulcer: Therefore the Chirurgion shall have regard to two things, that is, the resolving of the tumor, and the drying up of the ulcer, for every ulcer requires drying, which can never be attained unto, unlesse the swelling be taken away. Therefore because the chiefeest care must be to take away the Tumor, which unlesse it be performed there can be no hope to heale the ulcer, he shall lay this kinde of medicine to dissolve and dry, as *R. Cerusa & tuthie prepar. an. ʒij. ol. ros. & adipis capon. an. ʒij. corticis pini ussi, & loci, ʒss cera quantum satis, fiat unguentum.* Or *R. Farin. hordei & lent. an. ʒij, coquantur in decocto corticis mali granati, balauſt. plantag. addendo pulveris rosar. rub. absinth. an. ʒss. olei Myrtillor. & mellis com. an. ʒvj, fiat unguentum, ut artis est.* But for an *Herpes Miliaris* these must chiefly be used, *R. pulv. gallarum, malicory, balauſt. boli armeni an. ʒj. aqua ros. ʒiij, aceti acerrimi ʒj. axungie anser. & olei Myrtillor. an. ʒss, terebinth. ʒj fiat unguentum ad usum.* I have often found most certaine helpe in *unguentum emulatum cum Mercurio*, for it kills the pustules, and partly waists the humor contained in them. Yet if the ulcer, not yet neither yeelds, but every day diffuses it selfe further and further, you shall touch the edges and lipps thereof with some acride medicine, as *Aqua fortis*, oyle of Vitriole, or such like, for by this kinde of remedy, I have oft times healed fretting ulcers, which seemed altogether incurable.

A rule for healing ulcers conjoined with tumors.

The force of Unguentum emulatum cum Mercurio. Medicines fit for restraining eating and spreading ulcers.

CHAP. XV.

Of Feavers, which happen upon Erysipelous Tumors.

S Feavers sometimes happen upon Inflammations, and Erysipelaes, which favour of the humor whereof they proceed, that is, Choler. Therefore seeing it is peculiar to Choler, to move every third day, it is no marvaile if great Inflammations bring with them Tertian Feavers, or Agues, which have their fit every third day; for it is called an Intermittent Tertian which comes every other day.

A vulgar description of an intermitting Tertian feaver.

The Primitive causes in generall are strong exercises, especially in the hot Sunne, the use of heating, and drying either meats or medicines, great abstinence joyned with great labour, care, sorrow; the antecedent causes are the plenty of choler in the body, an hot and dry distemperature either of the whole body, or of the liver onely: the conjunct cause is the putrefaction of the Cholericke humor lying in some plenty without the greater vessels, in the habit of the body.

The causes of Tertian feavers.

The signes, a shivering or shivering like as when we have made water in a cold winter morning, a great pricking, stretching, or stiffnesse, as if there were pins thrust into us over all our bodies, by reason of the acrimony of the cholerick humor driven uncertainly & violently over all the body, & the sensible membranous & Nervous particles at the beginning of the fit; then presently the heate becomes acride, the Feaver kindled, like a fire in dry straw; the pulse is great, quicke and equall; the tongue dry; the urine yellowish, red and thin. The Symptomes are watchings, thirst, talking idly, anger, disquietnesse & tossing the body at the least noise or whispering. These Feavers are terminated by great sweats. They are incident to cholericke young men, such as are leane, & in Summer; after the fit oft times follow cholericke vomiting & yellowish stooles. After the fit there followes an absolute intermission retaining no reliques of the Feaver, untill the approach of the following fit, because all the cholericke matter by the force of that fit & nature is easily cast out of the body, by reason of its natural levity & facility; whereas in Quotidians there is no such thing, as which after the fit alwaies leave in the body a sense & feeling of a certaine inequality by reason of the stubbornesse of the Phlegmatick humor, & dulnesse to motion. The fit commonly uses to endure 4, 5, or 6 houres, although at sometime it may be extended to 8 or 10. This Feaver is ended at 7 fits, and usually is not dangerous, unlesse there be some error committed by the Physician, Patient, or such as attend him. Tertians in summer are shorter, in winter longer.

The signes of an intermitting Tertian.

The Symptomes,

Why Tertians have an absolute cessation of the feaver at the end of each fit.

Wherefore the beginning of the fit is accompanied with stiffnesse, or stretching.

the state with sweate, whereupon if the nose, lips or mouth breake forth into pimples or scabbes, it is a signe of the end of the Feaver, and of the power of nature which is able to drive the conjunct cause of the disease from the center to the habite of the body; yet these pimples appeare not in the declining of all Tertians, but onely then, when the Cholericke humor causing the Feaver shall reside in the stomacke, or is driven thither from some other part of the first region of the Liver. For hence the subtiler portion therof carryed by the continuation of the inner coate to the mouth and nose, by its acrimony easily causes pimples in these places. The cure is performed by Diet, and Pharmacy.

The Diet of
such as have
a Tertian.

When such as
have a tertian
may use wine,

The time of
feeding the
patient.

Therefore let the Diet be so ordered for the fixe things not naturall, that it may incline to refrigeration and humedtion, as much as the digestive faculty will permit, as Lettuce, Sorrell, Gourds, Cowcumbers, Mallowes, Barly Creames, Wine much alaid with water, thinne, small, and that sparingly and not before signes of concoction shall appeare in the urine; for at the beginning he may not use wine, nor in the declining, but with these conditions, which we have prescribed.

But for the time of feeding the patient, on that day the fit is expected, hee must eate nothing for three houres before the fit, lest the aguish heate lighting on such meats as yet crude, may corrupt and putresce them; whence the matter of the Feaver may be increased (because it is as proper to that heate to corrupt all things, as to the native to preserve and vindicate from putrefaction), the fit lengthened, and nature called away from the concoction and excretion of the Morbifick humor; yet wee may temper the severity of this law by having regard to the strength of the patient; for it will be convenient to feed a weake patient not onely before the fit, but also in the fit it selfe, but that onely sparingly, lest the strength should be too much impaired.

When to purge
the patient.

Now for Pharmacy; It must be considered, whether the strength of the Patient be sufficient, if the humors abound; for then you may prescribe *Diaprunum simplex*, *Cassia* newly extracted, the decoction of Violets, of Citrine Myrobalanes; Syrupes of Violets, Roses, of Pomegranats and Vineger. But if the powers of the Patient languish, hee must not onely not be purged, but also must not draw blood too plenteously, because Cholericke men soone faint, by reason of the facile and easie dissipation of the subtle humors and spirits; besides, such as are subject to tertian Feavers doe not commonly abound with blood, unlesse it be with Cholericke blood, which must rather be renewed, or amended by cooling and humedting things, than evacuated. Yea verily, when it is both commodious and necessary to evacuate the body, it may be attempted with far more safety by such things as worke by insensible transpiration, which provoke sweats, vomite or urine by reason of the subtilty of the Cholericke humor, than by any other. Also the frequent use of emollient glysters made with a decoction of Prunes, jujubes, Violets, branne and Barly, will profit much; If the patient fall into a *Delirium* or talke idly by reason of the heate and drynes of the head, with a particular excessse of the Cholericke humor, the head must be cooled by applying to the Temples and forehead and putting into the nose oyle of Violets, Roses, or womans milke. Let the feete and legs be bathed in faire and warme water, and the soles of the feet be anoynted with oyle of Violes and such like.

In the declining, a Bath made of the branches of Vines, the leaves of Willowes, Lettuce and other refrigerating things boyled in faire water, may be profitably used three houres after meat eaten sparingly.

When the time
is fit to use a
Bath.

But I would have you so to understand the Declination or declining not of one particular fit, but of the disease in generall, that the humors already concocted, allured to the skin by the warmnesse of the bath, may more easily and readily breathe forth: he which otherwise ordaines a bath at the beginning of the disease, will cause a constipation in the skin and habit of the body, by drawing thither the humors peradventure tough and grosse, no evacuation going before.

What kinds of
evacuations are
most fit in a
Tertian.

Also it will be good after generall purgations to cause sweate by drinking White wine thinne and well tempered with water; but urine by a decoction of Smallage and Dill; Certainly sweate is very laudable in every putride Feaver,

Feaver, because it evacuates the conjunct matter of the disease, but chiefly in a Tertian, by reason that choler by its inbred levity easily takes that way, and by its subtilty is easily resolved into sweat. But that the sweate may be laudable, it is fit it be upon a criticall day, and be foreshewed by signes of concoction agreeable to the time and manner of the disease. Sweats when as they flow more slowly are forwarded by things taken inwardly and applyed outwardly; by things taken inwardly, as with white wine, with a decoction of Figgs, Raifons stoned, grasse roots and the like opening things; but by things outwardly applyed, as sponges dipped in a decoction of hot herbes (as Rosmary, Time, Lavander, Marjerome and the like) applyed to the Groines, Armeholes, and ridge of the backe.

Sudorificks.

You may for the same purpose, fill two Swines bladders with the same decoction, or else stone bottles, and put them to the feete, sides, and betweene the thighes. Then let this be the bound of sweating, when the patient begins to waxe cold, that is, when the sweate feelles no more hote, but cold.

But by the consent of all, blood must not be letten after the third fit, but presently at the beginning of the Feaver, according to the opinion and prescription of *Galen*; for seeing this Feaver for the most part is terminated at seven fits, if you stay untill the third fit be past, the Feaver will now be comē to its state; but *Hippocrates* forbide us to move any thing in the state, least nature then busied in concocting the disease, be called from its begun enterprise.

When blood must be let.

Aphor. 29. Sect. 2.

CHAP. XVI.

Of an Oedema or cold Phlegmaticke Tumor.

hitherto wee have treated of hote Tumors, now wee must speake of cold; Cold Tumors are onely two, an *Oedema*, and a *Scirrhus*; And for all that *Hippocrates* and the Ancients used the word *Oedema* for all sorts of Tumors in generall; yet by *Galen* and these Physitions which succeeded him, it hath beene drawne from that large and generall signification, to a more strait and speciall, onely to designe a certaine species, or kinde of Tumor.

Gal. lib. de tumor. prater natur.

Wherefore an *Oedema* is a soft, laxe and painlesse Tumor, caused by collection of a phlegmaticke humor.

What an Oedema is.

The Ancients made eight differences of Tumors proceeding of Phlegme. The first they termed a true and lawfull *Oedema* proceeding from naturall Phlegme; from unnaturall Phlegme by admixtion of another humor they would have three sorts of Tumors to arise, as that by mixture of blood, should be made an *Oedema Phlegmonodes*, and so of the rest.

The differences of Oedemas.

Besides, when they perceived unnaturall Phlegme either puffed up by flatulency, or to flow with a waterish moisture, they called some *Oedemaes* flatulent, others waterish; but also when they saw this same Phlegme often to turne into a certaine Plaister-like substance, they thought that hence proceeded another kinde of *Oedema*, which they expressed one while by the name of *Atheroma*, another while by *Steatomia*, and sometime by *Melicerides*, as lastly they called that kind of *Oedema* which is caused by putride and corrupt flegme, *Scrophula*. For we must observe that Phlegme sometimes is naturall, and offends onely in quantity, whence the true *Oedema* proceeds; otherwhiles it is not naturall; and it becomes not naturall, either by admixtion of a strange substance, as blood, Choler or Melancholy, whence arise the three kinds of *Oedema's* noted formerly by the way; or by the putrednesse and corruption of its proper substance, whence the *Struma* and *Scrophula* proceed; or by concretion, whence kernells and all kinds of VVens, *Ganglia* and knots; or by resolution, whence all flatulent and waterish Tumors, as the *Hydrocele*, *Pneumatocle* and all kinds of Dropsies.

By how many waies Phlegme becomes not naturall.

The causes of all *Oedema's* are the defluxion of a Phlegmaticke or flatulent humor

6. Epid. sect. 58
lib. 23.

Lib. 2. ad
Glauc. cap. 3.
A rowler.

The signes are a colour whitish and like unto the skinnē, a soft Tumor, rare and laxe by reason of the plentiful moisture with which it abounds, and without paine, by reason this humor inferres no sense of heate nor manifest cold; when you presse it with your finger the print thereof remaines; because of the grossenesse of the humor and slownesse to motion. *Oedema's* breed rather in winter than in the summer, because winter is fitter to heape up Phlegme; they chiefly possesse the Nervous and Glandulous parts, because they are bloodlesse, and so cold and more fit by reason of their loosenesse to receive a defluxion; for the same cause bodies full of ill humors, ancient, and not exercised, are chiefly troubled with this kinde of Tumor.

An *Oedema* is terminated sometimes by resolution, but oftner by concretion, seldomer by suppuration, by reason of the small quantity of heate in that humor.

A Symptomatically *Oedema*, as that which followes upon a Dropsie or Consumption, admits no cure unlesse the disease be first taken away.

The generall cure is placed in two things, that is, in evacuation of the conjunct matter, prohibiting the generation of the antecedent. Wee attaine to both chiefly by foure meanes.

The first truly by ordaining a fit manner of living and prescribing moderation in the use of the fixe things not naturall. Wherefore we must make choyse of such aire as is hote, dry and subtle; wee must prescribe wine of a middle nature for his drinke; let the bread be well baked; let meates be appointed which may generate good blood, and these rather roasted than boyled. Let all fruites be forbidden, as also brothes and milke-meates; let him eate such fish as are taken in stony rivers; the Patient shall observe mediocrity in feeding, but principally sobriety in drinking, for feare of crudities; After meat let him use digestive powders, or common drige powder; if his belly be not naturally loose let it be made so by arte.

Let the Patient use exercise before meate, so by litle and litle to spend this humor, and restore the native heate. Let him sleepe litle, because much sleepe breedeth cold humors; let him avoyde grieffe and sadnesse. And if he be of a weake body, let him abstaine from venery, lest by another weakening by the use of venery added to his present infirmity, he fall into an uncureable coldnesse, from whence a greater measure of crudity will arise. Otherwise, if the body be strong and lusty, by such exercises and the moderate use of venery it will be the more dried and heated.

For so that sentence of *Hippocrates* is to be understood; That venery is a cure for Phlegmaticke diseases, as *Galen* in his commentaries tells us. The Physitian may performe the second intention by turning his counsell to that part, from whence the spring of this Phlegmaticke humour flowes. For if the infirmity arise from the stomacke, or from any other part, the part from whence it comes must be strengthened; if from the whole habite of the body, let attenuating, penetrating and opening medicines be prescribed. Wee performe the third intention by evacuating the humor impact in the part with locall medicines varied according to the foure times of the Tumor.

For *Galen* in the beginning and encrease prescribeth a fomentation of *Oxyratum* used with a sponge. But ifso be that the *Oedema* be upon the Arme or Leg, a repelling rowler is very good, that is, such an one as is brought from below upwards. So these medicines following are very fit for the same purpose, R. *Lixivij ex cineribus sarmentorum, & caulium, an. ℥iij. Tartari & Aluminis an. ℥℥, aceti ℥ij.* mixe all together and make a decoction, wherein wet sponges and foment the place. Also you may use the following Cataplasme, R. *farina hordei ℥iij. coquantur in Lixivio communi, addendo pulveris nucis cupressi, corticum granatorum, balausti. an. ℥j. Myrrha, Aloes, alum. an. ℥℥, olei Myrrill. ℥ij, fiat Cataplasma.* In the state and declination you must use

use drying and resolving medicines, as *R. Nucum cupressi, granat. sumach, balausti, an. ʒj. Salvia, organ. calament. Hyssopi, melissa an. m. j. absinthij, plantag. caude. equ. rapsi. barb. centinod. an. m. ꝑ. alumi. tartar. & salis com. an. ʒj. coquantur cum lixivio*; foment it with a spung, then presently apply this following Cataplasme. *R. Rad. Brionia ʒij. absinth. plantag. centin. chamem. meliloti, puleg. an. m. ꝑ. coquantur in hydromelise, pistentur, traycian-tur, addendo pulveris ros. rub. chamem. melil. an. ʒj. fiat Cataplasma.*

Lastly, you may here with good successe use resolving emplaisters and ointments, first heating or chafing the part by friction or fomentations aswell moist as dry; otherwise emplaisters will scarcely doe their duty, by reason of the great coldnesse of the part, being not sufficient of it selfe to assimilate the nourishment, or to expell the superfluous and unprofitable humor. Let a fomentation be made with white wine, in which Sage, Rosmary, Time, Lavander, Chamomile and Melilote flowers, red Roses, Orris roots, *Stachos* and such like have beene boyled, with a litle Vineger added thereunto. Quench hot bricke in the same decoction, and apply them wrapped in linnen clothes to the affected part, for so a vapour will breathe forth which hath an attenuating, pearcing, resolving and strengthening faculty. But you may in stead of the bricks fitly apply Hoggs or Oxe bladders, filled halfe full with the foresaid decoction, and that hot. The frictions must be made with hot linnen clothes, for so the native heate together with the blood and spirits is recalled to the part, and fuliginous humors contained under the skinn are resolved, whereby the strength of the part is in some sort recovered.

What caution
to be had in
application of
Emplaisters.

CHAP. XVII.

Of the cure of flatulent and waterish Tumors.

Formerly declared that not onely flatulent and waterish Tumors were comprehended under this word *Oedema*, but also such as are bred of congealed Phlegme, as *Atheromata, Steatomata* and *Melicerides*. Flatulent or windy Tumors are caused by vapour and winde kept in or contained sometimes under the skinn, somewhiles under the membranes, as the *Periostium* and *pericranium*, whereupon ensues cruell torment by reason of the distention of these parts which are endued with most exquisite sense. Sometimes the Entrailles, as the stomacke and Guts are swollen and stretched out with winde, as in a Tympany.

In what places
flatulencies
may be gathered.

They in this differ from a true and legitimate *Oedema*, that when you lay your finger upon them and take it off againe, there remaines no signe of the pressure thereof, because they are distent by vapour and not by humor, for the vapour being pressed returnes speedily againe, as you may perceive by balles or bladders filled with winde.

In what flatu-
lent tumors
differ from a
true *Oedema*.

The cause of such Tumors is the weakenesse of the native heate, not being able easily to resolve and waste the Phlegme by which the windy Tumors are raised, for so the morning Sunne (which in some sort resembles our native heate) cannot resolve the mists disperfed in the aire, which at noone it easily resolves into pure aire. Almost after the same manner our weaker heate stirs up vapours from that flegme it could not dissolue, which vapours are the matter of inflations, or swellings. But oft times although the native heate be sufficiently powerfull, yet because the humor lyeth deepe, or is kept in by the thicknesse of some membrane, tendon or Ligament, the stirred up vapour cannot exhale, whereby it comes to passe, that increased by litle and litle it causes a Tumor.

The causes of
flatulent Tu-
mors.

The signes of such a Tumor are a certaine renitency or resistance perceived by pressing it with your finger, and sometimes a noise as if you smit upon a drum,

The signes of
such Tumors.

especially if much winde be contained therein, such as is often gathered together in the hollownesse of the belly, and in the spaces betweene the larger muscles. The Tumor is neither red nor hot, but rather cold and white as in an *Oedema*. It often possesseth the joints, and especially the knees, and it is very difficult to be resolved. If such flatulency be gathered together in the Guts, it causeth the winde Collicke, in which sometimes the distention is so great that death ensues by reason of the renting or tearing the coats of the Guts.

CHAP. XVIII.

Of the cure of a flatulent and waterish Tumor.

Diet.
Things
strengthening
the parts,

Medicines evacuating the
conjunct matter.

Galen's fomentation.

Corroborating medicines

The signes of
a waterish
Tumor.

I shall chiefly and principally cure flatulent and waterish tumors by three meanes. First by the same diet which wee prescribed in an *Oedema*; then by strengthening the parts appointed for concoction, as the stomacke & Liver, chiefly by the temperate use of Aromaticke things as *Diacuminum*, *Diacalamentum*, *Aromaticum caryophyllatum*, *Aromaticum Rosatum*; and the like, to be prescribed according to good liking of the Physitian which oversees the cure; lastly by taking away of the conjunct matter by hot, drying and attenuating medicines which they call Carminative, that so the part being rarified the humor and flatulency therein contained may be discussed and dissipated. But remedies of this nature must be varied according to the variety of the parts; for some things are fit to be applied to the stomacke, others to the Guts, others to the joynts, and others to the fleshy parts; for the Collicke you must inject carminative glisters, let resolving *Sacculi* or Baggs be applyed, and cupping Glasses fastened to the Navel; if an outward part be affected, we use fomentations, liniments, chiefly if paine torment; as also Cataplasmes and Emplaisters, as *R. Florum chamam. melil. roris. marini, rosar. rub. an. p. j. absinth. hyssopi, an. m. ij.* let them be boiled in Lye, adding a litle vinegar for a fomentation to be used with sponges.

Galen foment the part with Rose-vinegar and a litle salt put thereto, and would have a sponge dipped therein to lye somewhat long upon the part. *℞. Olei chamam. aneth. rut. & liliorum, an. ℥ss, cera alba ℥vj; aq. vite ℥j,* let them all be mixed together and make a liniment, with which anoint the part after the fomentation. *℞. Farina fabar. orobi, an. ℥ij, coquantur in decocto pulegij, origani, calamentum. salvia, addita pulverum chamam. & melilot. an. m. ss. fursur. farina fab. & orobi, an. ℥ij, coquantur cum lixivio communi, addendo terebinth. ℥ij, oleor. aneth. & rut. an. ℥ij;* make an emplaister for the foresaid use.

The emplaister of *Vigo* with Mercury, and without is very good for the same purpose. But you must note, that such medicines must be applied to the part actually hot, and the same heat must be contained and renewed by putting about it linnen clothes, bricks, bottles and such like hot things.

The Humor and flatulency which were kept shut up in the part being resolved, the part must be strengthened, lest now and then it receive or generate the like matter. That may be done by the following fomentation and cataplasme. *℞. Nucum cupressi, corticum granat. sumach. berberis, balauft. an. ℥j, cauda equin. arnogloss. rupsi barb. absinth. salvia, roris. lavender. an. m. ss. flor. chamam. melil. rosar. anthos, an. p. j. alum. salis com. an. ℥j, bulliant omnia in aquis partibus aqua fabrorum & vini austeri,* make bagges for a fomentation, or use the decoction for the same purpose with a sponge. *℞. Farina fab. hordei & lupin. an. ℥ij. terebinth. com. ℥ij, pulver. radicis iros, mastic. an. ℥ss, mellis com. ℥ijss,* of the foresaid decoction as much as shall suffice, so to make a cataplasme to the forme of a poultice liquid enough, let it be applied hot to the affected part having used the fomentation before.

The signes of a waterish tumor are the same as of a flatulent; but over and besides it shines, and at the pressing with your fingers, there is hard a noyse or murmur as of a bladder halfe filled with water.

Therefore

Therefore the waterish tumor if it shall not yeeld to the forementioned resolving medicines, the way must be opened with an incision knife, after the same manner, as we mentioned in a Phlegmon. For often times this kind of remedy must be necessarily used, not onely by reason of the contumacie of the humor which gives no place to the resolving medicines, but also because it is shut up in its proper cyst or bagge, the thicknesse of which frustrates the force of the resolving medicines, neither suffers it to penetrate into the humor. As I some yeares agoe found by experience in a maid of 7. yeares old; which troubled with a *Hydrocele* or waterish rupture, to whom when I had rashly applyed to dissolve it resolving medicines of all sorts, at length I was forced to open it with my knife; not onely to evacuate the contained matter, but also that I might plucke out the bagge, which unlesse it were cut up by the roote, would be a meane to cause a relapse, *John Altine* doctor of Physicke called me to this businesse. *James Guilemeau* the Kings Chirurgion oversaw the cure.

Why a waterish tumor must be opened with an instrument;

A History.

CHAP. XIX.

Of an *Atheroma*, *Steatoma*, and *Meliceris*.

Although these Tumors may be thought comprehended under one genus with other *Oedematous* tumors, yet they differ as thus; that is, their matter is shut up in its bladder or bagge, as it were in a peculiar cell. But their difference amongst themselves is thus; the matter of the *Steatoma* as the name signifieth, is like unto Tallow [for *Στεας* in Greeke signifieth Tallow, or seame] yet it oft times is found stuffed with other divers hard bodies, stony, bony or callous like unto the claws of an hen. For *Philoxenus* reports that he sometimes saw flies in a *Steatoma* at the opening thereof, and such other like things wholly dissenting from the common matter of Tumors. The matter contained in an *Atheroma* is like to pappe, with which they feede little Children. A *Meliceris* containes matter resembling honey in colour and consistence; these Tumors appeare and rise without any Inflammation going before them. Thus you shall know these Tumors; a *Steatoma* is harder than the other two, neither yeelds it to the pressure of your finger, but when it once yeelds, it doth not speedily and easily returne to its former figure, because the matter is more grosse; It is of the same colour as the skin, without paine, and of a longish figure. The *Meliceris* yeelds to the touch, as being a loose and soft body, and as it is easily disposed and diffused, so it quickly returnes to its former place and Tumor. It differs from the *Atheroma* in figure and substance. For it is more globous and of a subtiler and more shining matter, besides also it takes up a large space, and is more obsequious to the touch, and for the rest, without paine. As for the manual operation of the Chirurgion in their cure, it seemes to bee of no great consequence of what sort the matter is, whether resembling tallow, honey, or pappe, for there is one simple manner of operation, which is, that you plucke away the contained humor, as also the receptacle in which it is contained. Yet you must note such Tumors, sometimes as it were hanging in the surface of the skin, are easily to be mooved this way and that way; but other some againe deeper fastned firmly cohere with the adjacent bodies, and these require an exquisite hand and also industry for feare of a great flux of blood and convulsion by cutting a veine. There are many other kinds of Tumors, as the *Testudo* or Mole, the *Nata*, the *Glandula*, *Nodus*, *Borium*, *Lupia*, which as in matter (for they are all of a thicke, clammy and viscous Phlegmaticke humor) so also in kinde they agree with an *Atheroma*, *Steatoma* and *Meliceris*. But also in these for the most part, when they are opened, you may see bodies of all sorts farre different from the common matter of Tumors, as stones, chalke, sande, coales, snails, strawes, or awnes of Corne, hey, horne, haire, flesh both hard and spongiouse, gristles, bones, whole creatures as well living as dead.

In what an *Atheroma*, *Steatoma*, and *Meliceris* differ.

Of Chirurgery to be used to these Tumors.

What the cause may be, that wee sometimes finde insects in these Tumors.

The generation of which things (by the corruption & alteration of humors) shal not make us much to admire it, if we consider, that as nature of all the seedes & elements

of

of the whole great world, hath made man the Microcosme or little world, that he might be, as it were, the lively Image of that greater world; so in him, it being never idle in us, would have all the kindes of all motions and actions to shew themselves, as long as matter for generation is not wanting. But because there is little, or rather no mention of these tumors amongst the ancients, we will briefly shew the opinions of the later Writers concerning them.

What the *Testudo* is.

Now they say, the *Testudo* is a tumor contrary to nature, soft, diffused, or vaulted, or arched like a Tortois, sometimes it arises in the head in forme of a Mole, and then it is called a Mole.

What the *Nata* is.

The *Nata* is a great and fleshy tumor, not in shape unlike a Melon, or rather the flesh of a mans buttockes, whence it may seeme to have had the name, unless wee had rather say it had it, because it more usually breeds upon the buttocks, than upon any other part of the body.

What a *Glandula* is.

The *Glandula* takes its denomination from an Acorne, called *Glaus* in Latine, the which it somewhat resembles in the compasse and forme of the tumor; or else because it most commonly breeds in the Glandules, or Emunctories of mans body.

What *Nodus*.

The *Nodus* or knot, is a round tumor, hard and immoveable, named from a rope tied on a knot.

Guido Cauliacensis affirms knots commonly to grow in nervous bodies; but at this time they more usually arise on the bones of such as have the French disease.

CHAP. XX.

Of the cure of *Lupia*, that is, *Wens*, or *Ganglions*.

What a *Ganglion* is.

Wen or *Ganglion* is a tumor sometimes hard, sometimes soft, yet alwayes round, using to breed in dry, hard, and nervous parts. And seeing that some of the tumors mentioned before in the former Chapter, sticke immoveable to the part to which they grow, because they are contained in no cyste, or bag; other some are moved up and down by the touch of your fingers, because they are contained in a bag or bladder, it commonly comes to passe that *Wens* have their bladder wherein to containe them, and therefore we thinke fit, the rather more freely, and particularly to treat of their cure, because they are more difficultly cured, especially where they are inveterate and of long standing.

The causes.

The primitive causes of these are dull blowes, fallings from high places, straines, and other such like occasions. But the antecedent and conjunct causes are the same with those of an *Atheroma*, *Meliceris* and *Steatoma*.

Signes.

The description formerly set downe, will furnish you with the signes by which you may know when they are present; certainly from very small beginnings they grow by little and little to a great bignesse, in the space of fixe or seaven yeares, some of them yeeld much to the touch, and almost all of them are without paine.

Their cure at the beginning.

You may hinder such as are beginning and first growing, from encrease by somewhat a strong and frequent rubbing with your fingers. For so their bagge or bladder, together with the skinne waxe thin, and the contained humor growes hot, is attenuated and resolved. But if so you nothing prevaile, you must lie upon them with your whole hand, or a flatted peece of wood as heavy as you can, untill such time as the cyste or bagge be broken by your impression; Then apply and strongly binde unto it a plate of lead, rubbed over with Quick-silver; for I have many times found by experience, that it hath a wonderfull force to resolve and waste the subject humor.

Plates of lead rubbed with Quick-silver.

A resolving plaister.

But if the *Wen* be in such a place in which you can make no strong impression, as in the face, chest, belly, and throat, let there be applied an Emplaister which hath a resolving force, such as this following hath; R, *gummi ammon. bdely. galban. an. ʒiij, liquefiant in aceto, & trajciansur per setaceum, addendo olei liliorum & lauri, an. ʒj, aqu. vite parum, pulveri, ireos, salis ammon. sulphur. vivi, vitrioli romani, an ʒʒ*; let them beall incorporated together, and make an Emplaister according to Art. But if the tumor

tumor cannot be thus resolved, it must be opened with a knife or cautery. And after the Eschar is removed, and the bagge waisted by *Ægyptiacum*, Mercury, and the like, the ulcer must be cleansed, replenished with flesh, and cicatrized.

Things to
waist or con-
sume the bag.

Sometimes Wens grow to so great a masse, that they cannot be cured by the described remedies, wherefore they must be taken away by the roote, by your hand and instrument, if so be that there be no danger by reason of their greatnesse, and so that they adhere not too closely to the adjacent parts, and if they be not too nigh to the greater veines and arteries; for it will be better in such a cause to let them alone. This shal be your way to cut the off, or take them away. A smal incision must be made even to the bladder, or bag, by which thrust in a probe of a fingers thicknes, hollowed in the midst, round at the end, and as long as neede shall require; then draw it many times about betweene the skinne and the bagge, even to the roote of the Wen, that so the skinne may be devided long wayes, then it will be requisite to make another incision overthwarte, so that they may intersect each other like a crosse; then presently draw the skinne from the bladder, from the corners of the Wen, towards the roote, and that with your finger covered with a fine linnen cloath, or else with a Razor if neede require.

The manner
to take away
Wens.

But you must observe that in a Wen there are alwayes certaine vessels, which are small in the beginning, but much encreased in processe of time, according to the encrease of the Wen, whereof they are as it were the rootes; wherefore if any *Hæmorrhagic* or fluxe of blood happen, let it be stopped by binding the vessels at their heads and roots, or make a strait ligature at the roots of the Wen, with a peece of whipcord, or with a manytimes doubled thred, and let the ends hang forth untill it fall away of its owne accord. Neither will it be sufficient to have cut away all this tumor, but also it will be fit to cut away portion of the skinne, wherewith the tumor was covered, and onely to leave so much as shall suffice to cover the part, then with a needle and threed draw together the lips of the incision, but in the interim let tents be put into the bottome of the ulcer untill it be perfectly censed, and the rest of the cure be workemanlike performed, even to the cicatrizing thereof.

The Chirurgeon *Collo* and I using this method, in the presence of Master Dr. *Vig-*
lanus the Kings Physition, tooke away a Wen from *Martiall Colard*, the Major of
Buron; it hanged at his necke, as bigge as a mans head, and it weighed eight pounds;
which made it so troublesome and burdensome to him, that he was forced to carry
it bound up in a towell, as in a scrip.

A History.

Verily if these kinde of tumors have a slender roote and broade top, they must be straitly tied and so cut off. But it is very difficult and full of dangerous chance to take away such Wens as are seated in the necke, neare unto the Iugular veines, these under the armeholes, in the groines, and such as are under the ham; by reason of the deadly force of such symptomes, as may thence arise. We can onely conjecture, not certainly say what kind of matter may be contained in them. We can onely know of what sort it is, when by incision it is presented to our sight. Yet in such as are very hard and doe much resist the touch, there are often found matters, which in consistence may be resembled to little stones, or pebles.

What Wens
to be cured by
ligature.
Which dange-
rous to cure.

I being on a time called to open the body of a great Lady, found in one of her breasts a body which might equall the bignesse of an Hens egge, hard, and compact like a rough peble; it was held, whilst she lived, both by the Physitions and Chirurgions to be a *Cancer*, because this hardnesse was very painefull to her, when it was but gently pressed downe.

A History.

But also some few yeares ago, I being called to the cure of a very honest woman, which was troubled with the same disease, strongly withstood the Physitions and Chirurgions affirming it to be a *Cancer*, for the tumor had taken no deepe roote, the habite of the part was not changed from the native colour, the veines about it were not swollen, neither was there any other convincing signe of a *Cancer*. For this same woman had her courses at their due and usuall time, and was well liking, and had a good colour in her face and body, was free from all sort of paine, unlesse when you pressed downe the part affected. Besides thenceforward the tumor grew not at all; no other evill accident befell her, yea verily she lives merrily, and well both in body and minde.

The matter of
a Wen is
sometimes tan-
ken for a *Can-*
cer.

Another His-
tory.

How you may
know a Wen
from a *Cancer*.

CHAP. XXI.

Of a Ganglion more particularly so called.

What a Ganglion properly so called is,

The causes.

What Ganglia may not be cured with iron Instruments.

Here are also certaine small tumors of the kinde of *Lupia* or Wens, which grow on diverse parts of the body, but chiefly on the wrists of the hands, and ankles of the feete, being called by a more particular name *Ganglia*; they appeare on the top of the skinn, neither doe they ever lie deepe. The cause of them is either the imbecilitie of a Nerve or Tendon got by wrestling, extension, a blow, labour, or other such like cause. Through which occasion the alimentary juyce which flowed to these parts, seeing it can neither be concocted, nor assimilated into the proper substance, is converted into an humor of the like nature cold, and grosse; which in continuance of time heaping it selfe up by little and little about the fibers, and the very substance of the tendon, concretes into a tumor.

It is not fit to use any iron instrument to these *Ganglia* which possesse the tendons and joints, but onely apply *Ammoniacum* and *Galbanum* dissolved in Vinegar and *Aqua vite*: as *R. gummi ammon. & sagapeni in aqua vite dissolutorum, ana. ʒj. coquantur super cineres calidos ad formam emplastri, sub finem adde sulphuris vivi subtiliter pulverisati. ʒß, fiat empl. ad usum.* Also the Emplaster of *Vigo* with double *Mercury* would be good for the same purpose.

The tumor softened by these remedies, must be wrought, rubbed, or pressed, so long, untill the bladder or bagge be broken under your fingers, which I have divers times done; then it will be expedient presently to apply and binde hard thereunto a plate of lead rubbed with Quicksilver, which may waste and consume the remainder of the tumor.

Sometimes there are *Ganglia* seene hanging by a small roote, as it were a string; wherefore they must be tied with a string at the roote, and every day twitched harder and harder, till such time as they fall off. The rest of the cure may be easily performed by the common rules of Art.

CHAP. XXII.

Of the Strumæ or Scrophulæ, that is, the Kings-Evill.

What the Scrophula or Kings-Evill is.

Their materia all cause. How they differ from other glandulous tumors.

The *Scrophula* are oedematous tumors arising in the glandulous parts, as the breasts, armpoles, groines, but chiefly in the glandules of the neck. They appeare either one or many, according to the quantity of that matter from whence they proceede, commonly contained in their proper cyste, or bagge, as *Atheromæ*, *Steatomæ*, and *Melicerides* are.

They are made of a grosse, cold, viscid, and phlegmaticke matter with some admixture of melancholy. They differ from other glandulous tumors; first in number, for most usually there appeare many of them united together, springing from somewhat a deeper roote than glandulous tumors doe; some of them are moveable, other some woven with the neighbouring nerves, remaining unremoveable.

Ganglia appeare fewer in number, and are without paine; but *Scrophula* oftentimes are painefull, especially when they waxe hot by putrefaction; so that sometimes they degenerate into cancerous ulcers, not to be touched by instruments, nor acride medicines.

Phlegmaticke, Melancholike, and gluttonous persons, and such as are accustomed to feede on cold and moist nourishments, as fish and cold water, and leade a sedentarie and idle life, are subject to the *Scrophula*. They are cured by a most slender diet, for so the native heate by want of nourishment turned upon the materiall cause of such like tumors, waste it.

Their cure by diet.

And

And they are cured by purging of the superfluous humors, and also by application of emollient resolving, and suppurative topicke medicines, after this following manner. R, *Mucaginis alth. sanogr. & sicuum ping. an. ʒij, olei liliorum, & chamam. an. ʒij, pinguedinis anseris & axungie porci ʒʒ, Terebinth. Ven. ʒʒ, ammoniaci, & galbani in aceto dissolutorum an. ʒij, cere nove quantum satis, fiat cerotum secundum artem ad modum diachyli magni.*

Emollient and resolving medicines.

The ointment for the French disease, and the Emplaister of *Vigo* with *Mercury*, are excellent for this purpose, especially if we continue so long, untill the Patient come to Salivation, for so Nature will disburden it selfe of the humor, generating the *Scrophule*, which I have sometimes tried with happy successe. R, *Emplastri diachyl. alb. & mag. ceroti & sopi descriptionis Philagri, ana. ʒij. Terebinth. clara ʒj, olei liliorum parum, fiat emplastrum satis molle.* But if the *Scrophule* cannot by this meanes be resolved, but as it oft times happens, tend to suppuration, you must use suppuratives, as R, *rad. alth. & liliorum, an. ʒij, coquantur in aqua communi, pistentur, trajecitis adde caput alliorum sub cineribus coctorum ʒij, olei liliorum, & ping. anseris & anat. an. ʒʒ, farina seminis lini quantum satis, formetur cataplasma.*

Suppuratives.

Here we must admonish the Chirurgeon, that he open not the *Scrophule* before that all the contained humor be fully and perfectly turned into *pus* or matter; otherwise the residue of the humor will remaine crude, and will scarce in a long time be brought to maturation; which precept must be principally observed in the *Scrophule*, and also sometimes in other abscesses, which come to suppuration. For we must not as soone as any portion of the contained humors appears converted into *pus*, procure and hasten the apertion. For that portion of the suppurated humor, causes the rest sooner to turne into *pus*, which you may observe in inanimate bodies. For fruits which begin to perish and rot, unless we presently cut away the putrifying part, the residue quickly becomes rotten; there is also another reason; The native heate is the efficient cause of suppuration; it therefore (the sore being opened) diminished and weakened by reason of the dissipation of the spirits, evacuated together with the humor, will cause the remaining portion of the humor, not to suppurate, or that very hardly, and with much difficulty. Yet if the tumified part be subject, by its owne nature, to corruption and putrefaction, as the fundament; if the contained matter be malignant, or criticall, it will be farre better to hasten the apertion.

A note to be observed in opening Scrophulous tumors.

Naturall heate the cause of suppuration.

There is also another way of curing the *Scrophule*, which is performed by the hand. For such as are in the necke, and have no deepe roots, by making incision through the skin, are pulled and cut away from these parts with which they were entangled. But in the performance of this worke, wee take speciall care, that we doe not violate or hurt with our instrument, the jugular veines, the sleepey arteries, or recurrent nerves. If at any time there be danger of any great efflux of blood, after they are plucked from the skn, they must be tied at their roots, by thrusting through a needle and thred, and then binding the thred strait on both sides, that so bound they fall off by themselves by little and little without any danger. The remainder of the cure may be performed according to the common rules of Art.

The Chirurgical manner of curing Scrophula.

CHAP. XXIII.

Of the Fever which happens upon an cedematous Tumor.

AVING shewed all the differences of cedematous tumors, it remaines that we briefly treat of the Symptomatical feaver, which is sometimes seene to happen upon them. This therefore retaining the motion of the humor by which it is made, is commonly of their kinde, which they name Intermitting Quotidians. Now the fit of a Quotidian comes every day, and in that repetition continues the space of eightene houres; the residue of the day it hath manifest intermission.

How an intermitting Quotidian happens upon cedematous tumors.

The cause of a Quotidian fea.

The primitive causes of this feaver are, the coldnesse and humidity of the aire encompassing

compassing us, the long use of cold meates and drinckes, and of all such things as are easily corrupted, as Summer fruites, crude fishes, and lastly, the omission of our accustomed exercise.

The antecedent causes are a great repletion of tumors, and these especially phlegmaticke. The conjunct cause, is phlegme putrefying in the habite of the body, and first region thereof without the greater veines.

The Signes

The signes of this feaver are drawne from three things; as first naturall; for this Feaver or Ague chiefly seizes upon these which which are of a cold and moist temper, as Old-men, Women, Children, Eunuches, because they have abundance of phlegme; and it invades Old-men by its owne nature, because their native heate being weake, they cannot convert their meates, then taken in a small quantity, into laudable bloud, and the substance of the parts. But it takes children by accident, not of its selfe, and the owne nature, for children are hot and moist; but by reason of their voracitie, or greedinesse, and their violent, inordinate, and continuall motion after their plentifull feeding, they heape up a great quantity of crude humors fit matter for this feaver; whereby it comes to passe, that fat children are chiefly troubled with this kinde of feaver, because they have the passages of their bodies strait and stopped; or because they are subject to Wormes, they are troubled with paine, by corruption of their meate; whence ariseth a hot distemper by putrefaction, and the elevation of putride vapours, by which the heart being molested, is easily taken by this kinde of feaver.

How children come to be subject to Quotidian feavers.

From things not naturall, the signes of this feaver are thus drawne. It chiefly takes one in Winter, and the Spring, in a cold and moist Region, in a sedentary and idle life, by the use of meates, not onely cold and moist, but also hot and dry, if they be devoured in such plenty, that they overwhelme the native heate.

How phlegmaticke humors happen to be generated by hot and dry meats.

For thus wine, although it be by faculty and nature, hot and dry, yet taken too immoderately, it accumulates phlegmaticke humors, and causes cold diseases. Therefore drunkenness, gluttony, crudity, bathes, and exercises presently after meate, being they draw the meats as yet crude into the body and veines, and to conclude, all things causing much phlegme in us, may beget a Quotidian feaver. But by things contrary to nature, because this feaver usually followes cold diseases, the Center, Circumference, and Habit of the body being refrigerated.

The Symptomes of quotidian.

The symptomes of this feaver are, the paine of the mouth of the stomacke, because that phlegme is commonly heaped up in this place, whence followes a vomiting, or casting up of phlegme; the face lookes pale, and the mouth is moist without any thirst, often times in the fit it selfe; because the stomacke flowing with phlegme, the watery and thinner portion thereof continually flowes up into the mouth and tongue, by the continuitie of the inner coate of the ventricle common to the gullet and mouth.

The manner of the pulse and heate in a Quotidian.

It takes one with coldnesse of the extreame parts, a small and deepe pulse, which notwithstanding in the vigour of the fit, becomes more strong, great, full, and quicke. Just after the same manner, as the heate of this feaver at the first touch appeares mild, gentle, moist, and vaporious; but at the length it is felt more acride, no otherwise than fire kindled in greene wood, which is small, weake, and smokie at the first, but at the length when the moisture being overcome, doth no more hinder its action, it burnes and flames freely.

Criticall sweats.

The urine.

The Patients are freed from their fits with small sweats, which at the first fits breake forth very sparingly, but more plentifully when the *Crisis* is at hand; the urine at the first is pale and thicke, and sometimes thinne, that is, when there is obstruction. But when the matter is concocted, as in the state, it is red: if at the beginning of the fit they cast up any quantity of phlegme by vomite, and that fit be terminated in a plentifull sweate, it shewes the feaver will not long last; for it argues the strength of nature, the yeelding and renuicie of the matter flying up, and the excretion of the conjunct cause of the feaver.

Why Quotidians are oft times long. In to what diseases a quartaine usually changes.

A Quotidian feaver is commonly long, because the phlegmaticke humor being cold, and moist by nature, is heavic and unapt for motion; neither is it without feare of a greater disease, because oft times it changes into a burning, or quartaine feaver, especially

especially if it be bred of salt Phlegme; for saltnesse hath affinity with bitternesse, wherefore by adustion it easily degenerates into it, so that, it neede not seeme very strange, if salt Phlegme by adustion turne into choler, or Melancholy. Those who recover of a quotidian Feaver, have their digestive faculty very weake; wherefore they must not be nourished with store of meats, nor with such as are hard to digest. In a quotidian the whole body is filled with crude humors, whereby it comes to passe that this Feaver oft times lasts sixty dayes. But have a care, you be not deceived, and take a double tertian for a quotidian, because it takes the patient every day as a quotidian doth. Verily it will be very easie to distinguish these Feavers by the kinde of the humor, and the propriety of the Symptomes and accidents; beside, quotidianians commonly take one in the evening, or the midst of the night, as then when our bodies are refrigerated by the coldnesse of the aire caused by the absence of the Sunne. Wherefore then the cold humors are moved in us, which were bridled a litle before by the presence and heate of the Sunne. But on the contrary, double tertians take one about noone. The shortnesse and gentlenesse of the fit, the plentiful sweat breaking forth, the matter being concocted, causes us to thinke the quotidian short and salutary.

How to distinguish a quotidian from a double tertian.

The Cure is performed by two meanes; to wit Diet and Pharmacy. Let the Diet be slender and attenuating, let the patient breathe in a cleere aire moderately hot and dry; let his meats be bread well baked, cocke or chicken brothes in which have bin boiled the roots of Parsly, Sorrell and the like.

Diet.

Neither at some times will the use of hot meats, as those which are spiced and salted, be unprofitable, especially to such as have their stomacke & liver much cooled. Let him eat Chickins, Mutton, Partridge and small Birds, river fishes and such as live in stony waters fryed or broiled, reare Egges and such like. These fruits are also good for him, Raisons, stewed Prunes, Almonds and Dates. Let his drinke be small white wine mixed with boyled water. Moderate exercises will be good, as also frictions of the whole body: sleepe taken at a fitting time, and proportioned to waking, so that the time of sleepe fall not upon the time of the fit; for then it hurts very much; for calling the heat to the inner parts, it doubles the raging of the feaverish heat inwardly in the bowells.

When the use of spiced and salted meats are fit.

When sleepe is hurtfull.

For the passions of the minde, the patient must be merry, and comforted with a hope shortly to recover his health. It seemes not amisse to some, at the coming of the fit to put the feet and Legs into hot water, in which Chamomill, Dill, Melilote, Marjerome, Sage, and Rosemary have beene boyled.

The Medicines shall be such Syrupes as are called digestive and aperitive, as Syrupe of Wormewood, Mints, of the five opening rootes, *Oxymel* with a decoction of Chamomill, Calamint, Melilot, Dill and the like, or with common decoctions. The Purgatives shall be *Diaphanicon*, *Electuarium Diacarthami*, *Hiera picra*, Agaricke; Turbith; of which you shall make potions with the water of Mints, Balme, Hyssope, Sage, Fennell, Endive or the like, *Pillule aurea* are also good. These purgatives shall sometimes be given in forme of a bole with Sugar, as the Physition being present shall thinke most fit and agreeable to the nature of the Patient.

Medicines.

About the state of the disease, you must have a care of the stomake and principally of the mouth thereof, as being the chiefe seate of Phlegme; wherefore it will be good to anoynt it every other day with oyle of Chamomill mixed with a litle white wine, as also to unlade it by taking a vomit of the juice of Raddish, and much *Oxymel*, or with the decoction of the seeds and roots of *Asarum* and Chamomill; and Syrupe of vineger will be very good, especially at the beginning of the fit, when nature and the humors begin to move; for an inveterate quotidian, though you can cure it by no other remedy, nothing is thought to conduce so much as one dram of old Treacle taken with Sugar in forme of a Bole, or to drinke it dissolved in *Aqua vite*.

Care must be had of the stomacke.

Vomits.

The use of Treacle in an inveterate quotidian.

CHAP. XXIII.

Of a Scirrhus, or an hard Tumor proceeding of Melancholy.

What a true
and legitimate
Scirrhus is,

What an illegi-
timate Scirrhus
is.

The signes.

Prognosticks.

Having shewed the nature of Tumors caused by blood, choler and Phlegme, it remaines we speake of these, which are bred of a Melancholike humor; Of these there are said to be foure differences. The first is of a true and legitimate *Scirrhus*, that is, of an hard Tumor endued with little sense, and so commonly without paine, generated of a naturall Melancholike humor. The second is, of an illegitimate *Scirrhus*, that is, of an hard Tumor insensible, and without paine, of a Melancholike humor concrete by too much resolving and refrigerating. The third is of a cancerous *Scirrhus* bred by the corruption and adustion of the Melancholike humor. The fourth of a Phlegmonous, *Erysipelous* or *Oedematous Scirrhus*, caused by Melancholy mixed with some other humor. The cause of all these kinds of Tumors is a grosse, tough and tenacious humor concrete, in any part. But the generation of such an humor in the body happens either of an ill and irregular diet, or of the unnaturall affects of the liver or spleene, as obstruction; or by suppression of the *Hæmorrhoides* or Courses.

The signes are hardnesse, renitency, a blackish colour, and a dilatation of the veines of the affected part with blackishnesse, by reason of the abundance of the grosse humor. The illegitimate or bastard *Scirrhus* which is wholly without paine and sense, and also the cancerous, admit no cure, and the true legitimate scarce yeeld to any. Those which are brought to suppuration, easily turne into cancers and fistulaes; these tumors though in the beginning they appeare little, yet in proceesse of time they grow to a great bignes.

CHAP. XXV.

Of the Cure of a Scirrhus.

Diet.

Lib. 2. Ad
Glauconium.

Emollients.

The Cure of a *Scirrhus* chiefly consists of three heads. First, the Physitian shall prescribe a convenient diet, that is, sober and moderate in feeding, tending to humidity, and indifferent heate; for his manner of life, let it be quiet and free from all perturbation of anger, greife and sadnesse, as also abhorring the use of venery. The second is placed in the evacuation of the antecedent matter, as by Phlebotomy, if need require, and by purging, by procuring the *hæmorrhoids* in men and the courses in women; let purgations be prescribed of *Diacatholicon*, *Hyera*, *diasenna*, polipody, *Epythymum* according to the minde of the learned Physitian. The third consists in the convenient use of Topicke medicines, that is, emollient at the beginning, and then presently resolving, or rather such as are mixed both of resolving & emollient faculties, as *Galen* teaches; for by the use of only emollient things there is danger of putrefaction and a Cancer, and only of resolving there is feare of concretion the subtiler part being resolved, and the grosser subsiding.

The emollient shall be thus: *R. Rad. alb. lib. f. rad. liliorum ℥iij. coquantur in aqua com. pistentur, trayciantur per setaceum, addendo olei chamem. & lilior. an. ℥j. asipi humida ℥℔. emplastrum diachyl. alb. cum oleo liliorum dissoluti ℥iij, cera alba quantum sit satis, fiat cerotum.* Or *R. gummi ammoniaci, galb. bdellij, styracis liquida in aceto dissolutorum, an. ℥j. diachyl. mag. ℥℔, olei liliorum, & axungia anseris, an. ℥j. ceroti asip. descriptione Philagr. ℥ij. liquefiant omnia simul, cera quantum sit satis, ut inde fiat cerotum satis molle.* When you have sufficiently used emollient things, fume the Tumour with strong Vinegar and *Aqua vite* poured vpon

a peice of a Millstone, flint or bricke heated very hot; for so the mollified humor will be rarified, attenuated, and resolved; then some while after renew your emollients, and then againe apply your resolvers to waste that which remaines, which could not be performed together and at once; for thus *Galen* healed a Scirrhus in *Cercilius* his sonne. Goats dung is very good to discusse Scirrhus tumors; but the Emplaster of *Vigo* with a double quantity of Mercury is effectually above the rest, as that which mollifies, resolves and wasts all tumors of this kinde.

Lib. 2. ad Gluc.

The efficacy of the Empl of *Vigo* with Mercury.

CHAP. XXVI.

Of a Cancer already generated.

Cancer is an hard Tumor, rough and unequall, round, immoveable, of an ash or livide colour, horrid by reason of the veines on every side, swollen with blacke blood, and spread abroad to the similitude of the stretched out legs and claws of a Crabb. It is a tumor hard to be knowne at the first, as that which scarce equals the bignesse of a Chicke, or *Cicer*, after a little time it will come to the greatnesse of a Hasell Nut, unless peradventure provoked by somewhat too acride medicines it sodainly encrease; being growne bigger, according to the measure of the encrease it torments the patient with pricking paine, with acride heat, the grosse blood residing in the veines growing hot, and inferring a sence like the pricking of Needles, from which notwithstanding the Patient hath oft times some rest. But because this kinde of Tumor by the veines extended & spread about it like claws and feet, being of a livide and ash colour, associated with a roughnesse of the skin and tenacity of the humor, represents, as it were, the toothed claws of the Crab, therefore I thought it not amisse here to insert the Figure of the Crabb, that so the reason both of the name and thing might be more perspicuous.

What a Cancer is.

The nature of the paine.

The reason of the name.

The figure of the Crabb, called Cancer in Latine.

CHAP. XXVII.

Of the causes, kinds, and prognosticks of a Cancer.

Here we acknowledge two causes of a *Cancer*, the antecedent, and conjunct. The antecedent cause depends upon the default of irregular diet, generating and heaping up grosse and feculent blood; by the morbidicke affection

The cause of a Cancer.

The causes of
a not ulcerated
Cancer.

of the Liver disposed to the generation of that blood; by the infirmity or weakness of the spleene in attracting and purging the blood; by the suppression of the Courses or Hæmorrhoids, or any such accustomed evacuation. The conjunct cause is that grosse and melancholicke humor sticking and shut up in the affected part, as in a strait. That melancholicke blood which is more milde, and lesse maligne, onely encreased by a degree of more fervide heat, breeds a not ulcerated Cancer, but the more maligne and acride causes, an ulcerated. For so the humor which generated Carbuncles, when it hath acquired great heat, acrimony, and malignitie, corrodes, and ulcerates the part upon which it alights. A Cancer is made more fierce and raging by meates inflaming the blood, by perturbations of the minde; anger, heate, and medicines too acride, oiely, and emplastricke, unfitly applied, both for time and place.

The sorts and
differences of
Cancers.

Amongst the sorts or kindes of Cancers, there be two chiefly eminent, that is, the ulcerated or manifest Cancer, and the not ulcerated, or occult. But of Cancers some possesse the internall parts, as the Guts, Wombe, Fundement; others the externall, as the Breasts; also there is a recent, or late bred Cancer, and also an inveterate one. There is one small, another great; one raging and maligne, another more milde. Every Cancer is held almost incurable, or very difficult to be cured, for it is a disease altogether maligne, to wize, a particular Leprosie. Therefore saith Aetius, a Cancer is not easily staied untill it hath eaten even to the innermost of the part which it possesses. It invades women more frequently than men, and those parts which are laxe, rare, fungous, and glandulous, and therefore opportune to receive a defluxion of a grosse humor, such are the Breasts and all the emunctories of the noble parts. When it possesses the Breasts, it often causes inflammation to the armeholes, and sends the swelling ever to the glandules thereof; whereupon the Patients doe complaine that a pricking paine even peirces to their hearts. But this same paine also runs to the clavicles, and even to the inner side of the shoulderblades and shoulders. When it is encreased, and covers the noble parts, it admits no cure but by the hand; but in decaied bodies, whose strength faile, especially if the Cancers be inveterate, we must not attempt the cure, neither with instrument, nor with fire, neither by too acride medicines, as potentiall Cauteries; but we must onely seeke to keepe them from growing more violent, and from spreading further, by gentle medicines, and a palliative cure. For thus many troubled with a Cancer, have attained even to old age. Therefore Hippocrates admonishes us, that it is better not to cure occult, or hidden Cancers; for the Patients cured (saith he) doe quickly die, but such as are not cured live longer.

Aetius lib. 16.

The parts
most subject
to Cancers.

What Cancers
one must not
undertake
truly to cure.

CHAP. XXVIII.

Of the Cure of a Cancer beginning, and not yet ulcerated.

Lib. 2. ad Glau.

 Cancer beginning is oft hindred from encreasing, before it fasten its roots, but when it hath once encreased, it admits no cure but by iron, as that which contemnes, by reason of the malignity & contumacy, the force of all medicines. Galen affirms, he cured a Cancer not ulcerated.

Now that cure is performed by medicines, purging melancholy, by Phlebotomy, when the strength and age of the Patient may well endure it, by shunning all things, which may breed ill and sæculent blood. The distemper of the Liver must first be corrected, the Spleene strengthened, as also the part affected; in men the Hæmorrhoids, in women their Courses must be procured.

Diet,

Therefore thicke and muddy wines, vinegar, browne bread, cold hearbes, old cheese, old and salted flesh, Beefe, Venison, goate, hare, garlick, onions and mustard, and lastly all acride, acide and other salt things, which may by any meanes incrassate the blood, and inflame the humors, must be

be eschewed. A cooling & humecting diet must be prescribed; fasting eschewed, as also watchings, immoderate labours, sorrow, cares, and mournings; let him use ptisans, and in his brotestboile Mallowes, Spinach, Lettuce, Sorrell, Purslaine, Succory, Hops, Violets, Borradge, and the foure cold seeds. But let him feede on Mutton, Veale, Kid, Capon, Pullet, young Hares, Partridges, Fishes of stony rivers, reare Egges; and use white wine, but moderately for his drinke.

The part affected with the *Cancer* must be gently handled, and not overburdened by over hard, or heavy things, or by too solide, or fat emplaisters; on the contrary gentle and mitigating medicines must be used; applying also at certaine times such things as resist venome or poyson, as Treacle and Mithridate. Asses milke is exceedingly fit to assuage the acrimony of the cancorous humor. Therefore it must not only be taken inwardly, but also applied outwardly to the cancorous ulcer, making thereof a fomentation.

How to handle the cancorous part,

Antidotes.
Asses milke.

CHAP. XXIX.

Of the cure of an ulcerated *Cancer*.

AN Ulcerated *Cancer* hath many signes common with that which is not ulcerated, as the roundnesse of the tumor, the inequality, roughnesse, and paine; to the judgement of the eye, the tumour seemes soft, but it is hard to the touch; the Ulcer is filthy, with lips thicke, swolne, hard, knotty, turned out, and standing up, having a horrid aspect, and casting forth ichorous, filthy, and carionlike filth, sometimes blacke, sometimes mixed with rotten filth, and otherwhiles with much blood. This kinde of ulcer is maligne, rebellious, and untractable, as that which contemnes milde remedies, and becomes more fierce, by acride and strong; the paine, feaver, and all the symptomes being encreased, from whence the powers are dejected, the wasting and consumption of the body followes, and lastly death. Yet if it be small, and in a part which may suffer amputation, the body being first purged, and blood drawne, the strength of the Patient not dissuading, it will be convenient to use the hand, and to take hold of, and cut away whatsoever is corrupt, even to the quicke, that no feare of contagion may remaine, or be left behind. The amputation finished, the blood must not be presctly stopped, but permitted to flow out in some measure, yea verily pressed forth all about it, that so the veines swollne with blacke and melancholicke blood may be disburdened. When you have taken a sufficient quantity of blood, the place must be seared with an actuall cautery. For that will strengthen the part affected, draw forth the venenate quality, and also stay the defluxion. Then must you apply mitigating medicines, & procure the falling away of the Eschar. To conclude, that which remaines, must be performed according to the cure of other ulcers. Now we know and understand that all the *Cancer* is cut away, and all the malignity thereof extinct, when the ulcer casts forth laudable matter, when that good flesh begins to grow by little and little, like to the graines of a Pomegranate, the pricking paine, and all the symptomes being asswaged. Yet the cure of an ulcerated *Cancer*, which shall possesse the lips may be more happily and mildly performed, no causticke medicine being applied after section, so also that scarce any deformity will be left, when it is cicatrized. Which new and never formerly tried, or written of way, as farre as I know, I found and performed in a man of fifty yeares old. Doctor *John Altine*, a most learned Physician being called to Counsell, *James Guillemeau*, and Master *Eustachius*, the Kings Chirurgions, and *John Le Jeune* the Duke of Guise his most worthy Chirurgion being present.

The Signes.

How and where a *Cancer* may be cut away. What to be observed in cutting away a *Cancer*.

The benefit of applying a cautery after amputation of the *Cancer*.

Signes that a *Cancer* is well taken away.

The way is this; The *Cancer* must be thrust through the lips on both sides, above and below with a needle and threed, that so you may rule and governe the *Cancer* with your left hand; by the benefit of the threed (least any portion thereof should scape the instrument in cutting) and then with your Sizars in the right hand, you may cut it off all at once, yet it must be so done, that some substance of the inner part of the lippe, which is next to the teeth, may remaine, (if so be that the *Cancer* be

A new and observable way of taking away a *Cancer* from the lippe.

not growne quite through) which may serve as it were for a foundation to generate flesh to fill up the hollownesse againe. Then when it hath bled sufficiently, the sides & brinckes of the wound must be scarified on the right and left sides, within, and without, with somewhat a deepe scarification, that so (when we would draw together the sides and lips of the wound, by that manner of stitching, which is used in an hare-lippe) we may have the flesh more pliant and tractable to the needle and threed. The residue of the cure must be performed just after the same manner as we use in hare-lips; of which we shall treat hereafter.

CHAP. XXX.

Of the Topicke medicines to be applied to an ulcerated, and not ulcerated Cancer.

Repelling medicines,

At the beginning use repercussive medicines, such as are the juyces of Nightshade, Plantaine, Henbane, Lettuce, Sorrell, Housleeke, Water Lentill or Duckes-meate, Knotgrasse, Pomegranates, and the like. Also *oleum rosarum omphacinum*, the powders of Sumach, Berberies, Litharge, Ceruse, Burnt-lead, Tutia, Quicksilver, and the like. Of which you may compose Fomentations, Liniments, Ointments, Cataplasmes, Emplaisters. *Emplastrum Diacalcitheos* dissolved with juice of Nightshade, and oile of Roses is very fit for not ulcerated Cancers. *Pompholix*, or Tutia, washed in juice of Nightshade, or Plantaine, is very good for ulcerated Cancers. Besides this following medicine is very comendable.

R. *Lytharg. & cerus. an. ʒij, terantur in mortario plumb. cum oleo rosar. donec reaucantur ad consistentiam linimenti vel unguenti*; and there may be use of a resolving and repercussive ointment, as R. *plumbi usti loti, pomphol. thuris, an. ʒij, absinth. pontic. ʒss, olei rosarum ʒij, cera ʒvj, succi solani, quantum sufficit ad unguenti crassitudinem*. They very much commend Theodorickes Emplaister to assuage the paine of ulcerated Cancers.

Theodorickes Emplaister,

R. *Olei ros. cera alb. an ʒij, succi granat. & solani, an. ʒij, ceruse lota ʒj, plumbi usti, loti, & tutie prepar. an. ʒss, thuris, mastich. an. ʒij, fiat empl. molle*. This following ointment I have often used with good successe.

R. *Therciac. veter. ʒj, succi cancerorum ʒss, succi lactuca & olei rosar. an. ʒss, vitel. ovorum sub cinerib. coct. ij, camphor. ʒss, pistentur omnia in mortario plumb. & fiat unguentum*.

Leaches,

The application of whelps, chickens, &c.

Epist. 21. The estate of Erysimum.

The signes of the Cancer in the wombe.

R. *spum. argent. axungie porci recentis, cera alb. an lib. ʒss, olei boni ʒviij, vitel. ovorum assat. iiij, fiat unguent. servetur usui*. And when you will use it, mixe it with a little ointment of Roses. I have also mitigated great paine by applying Leaches to an ulcerated Cancer, in that part where the torment was most vehement, by disburdening the part of some portion of the malignant humor; which same thing I have done by application of young Whelpes, or Kittlings, or Pidgions, or Chickens cut long wayes, and presently applied to the ulcer, and now and then changed, as soone as their heat seemes dissolved; and others applied for the naturall heat in an anodyne or mitigating medicine. *John Baptista Theodosius* in his Epistles, writes, that a cataplasme of the herbe *Erysimum*, or Cadlocke, being beaten, is very good to be applied to a Cancer not ulcerated; but if the Cancer be ulcerated, he boiles this same herbe in *Hydromel*, and so by injections and lotions clenches the ulcer, and mitigates the paine. If the Cancer affect the wombe, the patient feels the pricking of the paine in the groines above the *peeten*, and in the Kidneyes, & is often troubled with a difficulty of making water; but when it is ulcerated it poures forth filth or matter exceeding stinking & carion-like, and that in great plenty; the filthy vapour of which carryed up to the heart and braine, causes often swoounding. Now to mitigate the paines of such like places, the following medicines are of good use.

R. *Mucag. semin. lini, fenugr. extract. in aqua rosar. & plantaginis quod satis est*; Of this being warme make a fomentation.

R. *Rad. Athea, ʒss. coquatur in hydromelite, pistetur, & traiciatur, addendo olei rosar. parum, fiat Cataplasma*. Also you shall make divers pessaries according to the different kinds of paine; also make injections of the juice of Plantaine, Knotgrasse, Lettuce, Purslaine, mixed together, and agitated or laboured in a leaden mortar with a little oile

oyle of Roses; for this kinde of medicine is commended by *Galen*, in every kinde of ulcerated *Cancer*. Also this following water is very profitable, and often approved by *me*. R. *Stercoris bubuli* lb. .iiij. *herba Roberti*, *plantag*, *semper vivi*, *hyoscyami*, *portulac*, *lactuc*, *endiv*, an. m. j. *cancros fluiatiles*, num. xij. let them be all beaten together and distilled in a leaden Alembicke, keepe the liquor for use and with it make often injection into the part; or if the site of the part will permit, let the cancerous ulcers be washed therewith, and pledgets of lint steeped therein be applyed and renewed ever and anon; for so the acrimony and force of the inflammation is re-
Lib. 9. Simpl.

tunded, and the paine asswaged. *Galen* beats into powder river Crabs burnt; the powder mixed with oyntment of Roses is most profitably applyed upon lint to cancerous ulcers.
Lib. 4. de comp. med. secundum gener.

It will be very convenient to put into the necke of the wombe the following instrument made of Golde, or Silver, whereby the cancerous filth may have free and safe passage forth, and the filthy and putredinous vapours may more easily breathe forth. Therefore let it be hollow quite through; some five or sixe fingers long, and about the bignes of ones Thumbe, at the upper end, perforated with many holes whereby the filth may have passage forth. Let the outer or lower end be some two fingers thicke in the circumference, make it with a neat springe, that may hold that end open more, or lesse according to the Physitions minde; let there be two strings, or laces put unto it, by which being tyed before and behinde to the rowler, with which the woman shall girt her loynes, the Device may be kept from falling, as you may see in the following figure.

A Vent made like a Pessary for the wombe affected with a Cancerous ulcer.

A. Shewes the upper end perforated with five or sixe holes.

B. The Lower end.

C. That part of the end which is opened by the springe, which is marked with the letter D.

E. The strings, or laces.

Neither is that remedy for not ulcerated cancers to be contemned, which consists of a plate of lead besmeared with quick-silver; for *Galen* himselfe testifies that lead is a good medicine for malignant and inveterate ulcers. But *Guido Cauliacensis* is a witnesse of ancient credit and learning, that such plates of lead rubbed over with quick-silver, to such malignant ulcers as contemne the force of other medicines, are as it were Antidotes, to waffe and overcome their malignity and euill nature. This kinde of remedy, when it was prescribed by that most excellent Physition *Hollerius*, who commanded me to apply it to the Lady of *Montigni* maide of Honor to the Queene mother, troubled with a *Cancer* in her left brest, which equalled the bignes of a Walnut, did not cruelly throughly heale it, yet notwithstanding kept it from further growth,

Wherefore

Lib. 9. simp.

Plates of Lead

A History.

Wherefore at the length growing weary of it, when shee had committed her selfe to a certaine Physitian boldly promising her quicke helpe, she tryed with losse of her life, how dangerous, and disadvantageous that cure of a *Cancer* was, which is undertaken according to the manner of healing other ulcers; for this Physition, when he had cast away this our medicine, and had begun the cure with mollifying, heating and attractive thing, the paine, inflammation and all the other Symptoms encreasing, the Tumor grew to that bignes; that being the humor drawne thither could not be contained in the part it selfe, it stretched the brest forth so much, that it broke it in the middle, just as a Pomegranate cleaves when it comes to its full maturity; whereupon an immoderate fluxe of blood following, for staying whereof hee was for to strew causticke powders thereon; but by this meanes the inflammation and paine becomming more raging, and swooundings comming upon her, shee poore Soule in steed of her promised health, yeelded up her ghost in the Physitions bosome.

CHAP. XXXI.

Of the Feaver which happeneth in Scirrhus Tumors.

Why a quartaine happens upon scirrhus tumors.

Such a Feaver is a Quartaine, or certainly comming neare unto the nature of a Quartaine, by reason of the nature of the Melancholike humor of which it is bred. For this shut up in a certaine seat in which it makes the tumor, by communication of putride vapours heats the heart above measure, and enflames the humors contained therein, whence arises a Feaver. Now therefore a quartaine is a Feaver comming every fourth day, and having two dayes intermission.

The primitive causes thereof are, these things which encrease Melancholike humors in the body, such as the long eating of pulse, of course and burnt bread, of salte flesh and fish, of grosse meates as Beefe, Goate, Venison, olde Hares, olde Cheese, Cabbage, thicke and muddy wines and other such things of the same kinde.

The antecedent causes are a heaped up plenty of Melancholike humors abounding over all the body. But the conjunct causes are Melancholike humors putrifying without the greater vessels, in the small veines and habite of the body.

The signes.

We may gather the signes of a Quartaine feaver from things which they call naturall, not naturall, and against nature; from things naturall, for a cold and dry temper, olde age, cold and fat men, having their veines small, and lying hidde, their spleene swolne and weak, are usually troubled with quartaine Feavers.

Why they are frequent in Autumne.

Of things not naturall; this Feaver, or Ague is frequent in Autumne, not onely because, for that it is cold and dry, it is fit to heape up Melancholike humors; but cheifly by reason that the humors by the heate of the preceding Summer are easily converted into adust Melancholy, whence far worser and more dangerous quartaines arise, than of the simple Melancholike humor; to conclude, through any cold or dry season in a region cold and dry, men that have the like Temper easily fall into quartaines; if to these a painefull kinde of life full of danger and sorrow doth accrew.

Of things contrary to nature; because the fitts take one with painefull shaking, inferring as it were the sence of breaking or shaking the bones; further it taketh one every fourth day with an itching over the whole body, and oft times with a thinne skurfe and pustles especially on the legges; the pulse at the beginning is litle, slow, and deepe, and the urine also is then white and waterish, inclining to somewhat a darke colour.

In the declination when the matter is concocted the urine becomes blacke, not occasioned by any malignant Symptome or preternaturall excesse of heat, (for so it should be deadly) but by excretion of the conjunct matter. The fit of the Quartaine continues 24 houres, but the intermission is 48 houres. It often takes its originall

originall from an obstruction, paine, and *scirrhus* of the Spleene, and the suppression of the courses and Hæmorrhoides.

Quartaines taken in the Summer are for the most part short, but in the Autumne long, especially such as continue till Winter. Those which come by succession of any disease of the Liver, Spleene, or any other precedent disease, are worse than such as are bred of themselves, and commonly end in a Dropsie. But those which happen without the fault of any bowells, and to such a patient, as will be governed by the Physition in his Diet, infer no greater harme, but free him from more grievous and long diseases, as Melancholy, the Falling sicknesse, Convulsions, Madnesse, because the Melancholy humor, the author of such diseases, is expelled every fourth day by the force of the fit of the Quartaine.

Prognosticks.

From what diseases a quartaine takes one.

A Quartane Feaver, if there be no error committed, commonly exceeds not a yeare, for otherwise some Quartanes have beene found to last to the twelfth yeare according to the opinion of *Avicen*: the Quartane beginning in Autumne is oft times ended in the following spring; the Quartane which is caused by adust blood or choler or Salt flegme is more easily and sooner cured, than that which proceeds from an adust Melancholy humor, because the Melancholy humor, terrestriall of its owne nature, and harder to be dissolved than any other humor, is againe made by adustion (the subtiler parts being dissolved and the grosser subsiding) more stubborn, grosse, malignant and acride. The cure is wholly abolved by two meanes, that is, by Diet and medicines. The Diet ought to be prescribed, contrary to the cause of the Feaver in the use of the fixe things not naturall, as much as lyes in our power. Wherefore the Patient shall eschew Swines flesh, flatulent, viscid and glutinous meats, tenny fowles, salt meats and Venison, and all things of hard digestion. The use of white wine indifferent hot and thin is convenient to attenuate and incide the grosse humor, and to move urine and sweat; yea verily at the beginning of the fit a draught of such wine will cause vomiting, which is a thing of so great moment, that by this one remedy many have been cured. Yet if we may take occasion and opportunity to provoke vomit, there is no time thought fitter for that purpose than presently after meate; for then it is the sooner provoked, the fibers of the Stomach being humsted & relaxed, and the stomach is sooner turned to vomiting, whereupon followes a more plentiful, happy and calke evacuation of the Flegmaticke and Cholericke humor, and lesse troublesome to nature: and of all the crudities with which the mouth of the ventricle abounds in a Quartaine, by reason of the more copious afflux of the Melancholike humor, which by his qualities cold and dry, disturbs all the actions and naturall faculties. Moreover exercises and frictions are good before meate; such passions of the minde as are contrary to the cause from which this Feaver takes his originall, are fit to be cherished by the patient; as Laughter, Teasting, Musique, and all such like things full of pleasure and mirth. At the beginning the patient must be gently handled and delt withall, and we must abstaine from all very strong medicines untill such time, as the disease hath beene of some continuance. For this humor, contumacious at the beginning when as yet nature hath attempted nothing, is againe made more stubborn, terrestriall and dry, by the almost fiery heat of acride medicines. If the body abound with blood, some part thereof must be taken away by opening the Median or Basilick veine of the left arme, with this caution, that if it appeare more grosse and blacke, we suffer it to flow more plentifully; if more thin, and tinged with a laudable red Colour, that we presently stay it. The matter of this Feaver must be ripened, concocted and diminished with the Syrrupes of *Epithymum*, of *Scolopendrium*, of Mayden hayre, Agrimony, with the waters of Hopps, Buglosse, Borage and the like. I sincerely protest, next unto God, I have cured very many quartaines by giving a potion of a little Treakle dissolved in about some two ounces of *Aqua vite*; also sometimes by two or three graines of muske dissolved in Muskadine, given at the beginning of a particular fit towards the generall declination of the disease, after generall purgations the humor and body being prepared, and the powers strong; And certainly an inveterate Quartaine can scarce ever be dissolved unlessse the body be much heated with meates and medicines. Therefore it is not altogether to be disproved which many say, that they have driven away

Diet.

How much vomiting prevails to cure a Quartaine

Medicine.

What quartaines must be cured with refrigerating things.

What bastard agues are and how they must be cured.

way a quartaine by taking a draught of wine every day as soone as they came forth of their bed, in which some leaves of Sage had bin infused all the night. Also it is good a little before the fit to anoint all the spine of the backe with oyles heating all the nervous parts, such as are the oyle of Rue, Wallnuts, of the Peppers, mixing therewith a little Aqua vitæ. but for this purpose the oyle of *Castoreum* which hath beene boyled in an apple of *Coloquintida*, the Kernells taken out, uppon hot coles to the consumption of the halfe part, mixing therewith some little quantity of the powders of Pepper, Pelitory of Spaine and *Euphorbium*, is excellent. Certainly such like Inunctions are good not onely to mitigate the vehemency of the terrible shaking, but also to provoke sweats; for because by their humid heat they discusse this humor being dull and rebellious to the expulsive facultie, for the Melancholy is as it were the drosse and mudde of the blood. Therefore if on the contrary the Quartaine feaver shall be caused by adust choler, we must hope for and expect a cure by refrigerating and humective medicines, such as are Sorrell, Lettuce, Purslane, brothes of the decoction of Cowcumbers, Gourds, Mellons and Pompions. For in this case if any use hot medicines, he shall make this humor most obstinate by the resolving of the subtiler parts. Thus *Trallianus* boasts that hee hath cured these kinds of Quartane Feaver by the onely use of refrigerating *Epithemaes* being often repeated a little before the beginning of the fit. And this is the summe of the Cure of true and legitimate intermitting Feavers. That is, of those which are caused by one simple humor, whereby the Cure of those which they call bastard intermitting Feavers, may be easily gathered and understood; as which are bred by a humor impure and not of one kinde, but mixt or composed by admixture of some other matter; for example, according to the mixture of diverse humors Flegmaticque and cholericke, the medicines must also be mixt, as if it were a confused kinde of Feaver of a *Quotidian* and *tertian*; it must be cured by a medicine composed of things evacuating flegme and choler.

CHAP. XXXII.

Of an Aneurisma, that is, the dilatation, or springing of an Artery, veine, or Sinnew.

What it is.

N *Aneurisma* is a soft tumor yeelding to the touch, made by the blood and spirit powred forth under the flesh and Muscles, by the dilatation or relaxation of an Artery. Yet the author of the definitions seemes to call any dilatation of any venous vessell by the name of an *Aneurisma*. *Galen* calls an *Aneurisma* an opening made of the *Anastomasis* of an Artery. Also an *Aneurisma* is made, when an Artery that is wounded closeth too slowly, the substance which is above it being in the meane time agglutinated, filled with flesh and cicatrized, which doth not seldome happen in opening of Arteries unskilfully performed and negligently cured; therefore *Aneurismaes* are absolutely made by the *Anastomasis*, springing, breaking, *Erosion*, and wounding of the Arteries. These happen in all parts of the body, but more frequently in the throat, especially in women after a painfull travaile. For when as they more strongly strive to hold their breath, for the more powerfull expulsion of the birth, it happens that the Artery is dilated and broken, whence followes an effusion of blood and spirits under the skin. The signes are, a swelling one while great, another small, with a pulsation and a colour not varying from the native constitution of the skinne. It is a soft tumor, and so yeelding to the impression of the fingers that if it peradventure be small, it wholly vanisheth, the Arterious blood and spirits flying backe into the body of the Artery, but presently as soone as you take your fingers away, they returne againe with like celerity. Some *Aneurismaes* doe not onely when they are pressed, but also of themselves make a sensible hissing, if you lay your eare neare to them, by reason of the motion of the vitall spirit rushing with great violence through the straitnes of the passage.

In what parts they chiefly happen.

Wherefore

Wherefore in *Aneurismaes* in which there is a great rupture of the Artery, such a noyse is not heard, because the spirit is carryed through a larger passage. Great *Aneurismaes* under the Armpits, in the Groines and in other parts wherein there are large vessells, admit no cure, because so great an eruption of blood and spirit often followes upon such an incision, that death prevents both art and Cure. Which I observed a few yeares agoe in a certaine preist of Saint *Andrewes* of the Arches, M. *John Maillet* dwelling with the chiefe President *Christopher de Thou*. Who having an *Aneurisma* at the setting on of the shoulder about the bignes of a Wall-nut, I charged him, hee should not let it be opened, for if it did, it would bring him into manifest danger of his life, and that it would be more safe for him, to breake the violence thereof with double clothes steeped in the juyce of Night-shade and Houselike, with new and whayey cheese mixt therewith: Or with *Unguentum de Bolo* or *Emplastrum contra rupturam* and such other refrigerating and astringent medicines, if hee would lay upon it a thin plate of Lead, and would use shorter breeches that his doublet might serve to hold it too, to which hee might fasten his breeches instead of a swathe, and in the meane time he should eschew all things which attenuate and inflame the blood, but especially he should keepe himselfe from all great straining of his voyce. Although he had used this Diet for a yeare, yet he could not so handle the matter but that the tumor increased, which he observing goes to a Barber, who supposing the tumor to be of the kinde of vulgar impostumes, applies to it in the Evening a Causticke causing an Eschar so to open it. In the Morning such an abundance of blood flowed forth from the tumor being opened, that he therewith astonished, implores all possible ayde, and bids that I should be called to stay this his great bleeding, and he repented that he had not followed my directions. Wherefore I am called, but when I was scarce over the threshold, he gave up his ghost with his blood. Wherefore I diligently admonish the young Chirurgion that hee do not rashly open *Aneurismas* unlessse they be small in an ignoble part, and not indued with large vessells, but rather let him performe the cure after this manner. Cut the skinne which lyes over it untill the Artery appeare, and then separate it with your knife from the particles about it, then thrust a blunt and crooked needle with a thred in it under it, binde it, then cut it off and so expect the falling off, of the thred of it selfe whiles nature covers the orifices of the cut Artery with new flesh, then the residue of the cure may be performed after the manner of simple wounds. The *Aneurismaes* which happen in the internall parts are incurable. Such as frequently happen to those who have often had the unctiō and sweat for the cure of the French disease, because the blood, being so attenuated and heated therewith that it cannot be containd in the receptacles of the Artery, it distends it to that largeness as to hold a mans fist; Which I have observed in the dead body of a certaine Taylor, who by an *Aneurisma* of the Arterious veine suddenly whilest hee was playing at Tennis fell downe dead, the vessell being broken: his body being opened I found a great quantity of blood powred forth into the Capacity of the Chest, but the body of the Artery was dilated to that largeness I formerly mentioned, and the inner Coate thereof was bony. For which cause within a while after I shewed it to the great admiration of the beholders in the Physitions Schole whilest I publiquely dissected a body there; the whilst he lived said he felt a beating and a great heate over all his body by the force of the pulsation of all the Arteryes, by occasion whereof hee often swooned. Doctor *Sylvius* the Kings professor of Physicke at that time forbad him the use of Wine, and wished him to vse boyled water for his drinke, and Crudds and new Cheeses for his meate, and to apply them in forme of Cataplasmes upon the grieved and swolne part. At night he used a ptisan of Barley meale and Poppy-seedes, and was purged now and then with a Clyster of refrigerating and emollient things, or with Cassia alone, by which medicines hee said hee found himselfe much better. The cause of such a bony constitution of the Arteries by *Aneurismaes* is, for that the hot and fervid blood first dilates the Coates of an Artery, then breakes them; which when it happens, it then borrowes from the neighbouring bodies a fit matter to restore the loosed continuity thereof.

This matter whilest by litle and litle it is dried and hardened, it degenerats into a Gristely

of *Aneurismae*

Gristely or else a bony substance, just by the force of the same material and efficient causes, by which stones are generated in the reins and bladder. For the more terrestriall portion of the blood is dried and condensed by the power of the unnaturall heat containd in the part affected with an *Aneurismae*; whereby it comes to passe that the substance added to the dilated and broken Artery is turned into a body of a bony consistence. In which the singular providence of nature, the handmaide of God is shewed, as that which, as it were by making and opposing a new wall or bancke, would hinder and breake the violence of the raging blood swelling with the abundance of the vitall spirits; unlesse any had rather to refer the cause of that hardnesse to the continuall application of refrigerating and astringent medicines. Which have power to condensate and harden, as may not obscurely be gathered by the writings of *Galen*. But beware you be not deceived by the forementioned signes; For sometimes in large *Aneurismae*s you can perceive no pulsation, neither can you force the blood into the Artery by the pressure of your fingers, either because the quantity of such blood is greater than which can be containd in the ancient receptacles of the Artery, or because it is condensate and concrete into Clods, whereupon wanting the benefit of ventilation from the heart, it presently putrifies; Thence ensue great paine, a Gangren, and mortification of the part, and lastly the death of the Creature.

The End of the Seventh Booke.

THE

OF PARTICULAR TUMORS AGAINST NATURE.

THE EIGHT BOOKE

The Preface.

Ecause the Cure of diseases must be varied according to the variety of the temper, not onely of the body in generall, but also of each part thereof; the strength, figure, forme, site, and sence thereof being taken into consideration: I thinke it worth my paines, having already spoken of Tumors in Generall, if I shall treat of them in particular which affect each part of the body, beginning with those which assaile the head. Therefore the Tumor either affects the whole head, or

elle onely some particle thereof, as the Eyes, Eares, Nose, Cumms and the like. Let the *Hydrocephalos*, and *Physocephalos* be examples of those tumors which possesse the whole head.

CHAP. I.

Of an Hydrocephalos or watry tumor which commonly affects the heads of Infants.

He Greekes call this disease *Hydrocephalos*, as it were a Dropsie of the Head, by a waterish humor; being a disease almost peculiar to Infants newly borne. It hath for an externall cause the violent compression of the head by the hand of the Midwife or otherwise at the birth, or by a fall, contusion and the like. For hence comes a breaking of a veine or Artery, and an effusion of the blood under the skinne. Which by corruption becoming whayish, lastly, degenerateth into a certen waterish humor. It hath also an inward cause, which is the abundance of ferous and acride blood, which by its tenuity and heat sweats through the Pores of the vessells, sometimes betweene the Musculous skinne of the head and the *Pericranium*, sometimes betweene the *Pericranium* and the skull, and sometimes betweene the skull and the membrane called *Dura mater*, and otherwhiles in the ventricles of the braine.

The signes of it, contained in the space betweene the Musculous skinne and the *Pericranium*, are a manifest tumor without paine, soft, and much yeelding to the

What it is.

The causes.

Differences by reason of place

Signes.

pressure of the fingers. The Signes, when it remayneth betweene the *Pericranium* and the skull, are for the most part like the forenamed, unlesse it be that the Tumor is a little harder, and not so yeelding to the finger, by reason of the parts betweene it and the finger; And also there is somewhat more sence of paine. But when it is in the space betweene the skull and *Dura mater*, or in the ventricles of the Braine or the whole substance thereof, there is a dullnesse of the senses as of the sight and hearing; the tumor doth not yeeld to the touch, unlesse you use strong impression, for then it sincketh somewhat downe, especially in infants newly borne; who have their skulls almost as soft as waxe, and the junctures of their Sutures laxe, both by nature, as also by accident, by reason of the humor contained therein moistening and relaxing all the adjacent parts; the humor contained here lifts up the Skull somewhat more high, especially at the meetings of the Sutures, which you may thus know, because the Tumor being pressed, the humor flies backe into the secret passages of the braine.

To conclude, the paine is more vehement, the whole head more swollen, the forehead stands somewhat further out, the eye is fixt and immoveable, and also weepes by reason of the ferous humor sweating out of the braine.

A History.

Vesalius writes that hee saw a girle of two yeares old, whose head was thicker than any mans head by this kinde of Tumor, and the Skull not bonie, but membranous, as it useth to be in abortive birthes, and that there was nine pound of water ran out of it.

Abucrasius tells that he saw a child whose head grew every day bigger by reason of the watery moisture contained therein, till at length the tumor became so great, that his necke could not beare it neither standing nor sitting, so that hee died in a short time. I have observed and had in cure foure children troubled with this disease, one of which being dissected after it died, had a braine no bigger than a Tennis Ball. But of a Tumor and humor contained within under the *Cranium*, or Skull, I have seene none recover; but they are easily healed of an externall Tumor.

Therefore whether the humor lye under the *Pericranium*, or under the muscous skin of the head, it must first be assailed with resolving medicines, but if it cannot be thus overcome, you must make an incision, taking heede of the Temporall Muscle, and thence presse out all the humor, whether it resemble the washing of flesh newly killed, or blackish blood, or congealed or knotted blood, as when the tumor hath beene caused by contusion; then the wound must be filled with dry lint, and covered with double boulders, and lastly bound with a fitting ligature.

CHAP. II.

Of a Polypus, being an eating disease in the Nose.

The reason of the name.

Lib. 6. Cap. 8.

The differences thereof.

He *Polypus* is a Tumor of the Nose against nature, commonly arising from the *Os Ethmoides* or Spungye bone. It is so called, because it resembles the feet of a Sea *Polypus* in figure, and the flesh thereof in consistence. This Tumor stops the Nose, intercepting and hindering the liberty of speaking and blowing the Nose. *Celsus* saith the *Polypus* is a caruncle or Excrecence one while white, another while reddish, which adheres to the bone of the Nose, and sometimes fills the Nostrils hanging towards the lipps, sometimes it descends backe through that hole, by which the spirit descends from the Nose to the throtle; it growes so that it may be seene behinde the *Vula*, and often strangles a man by stopping his breath. There are five kinds thereof, the first is, a soft membrane, long and thin like the relaxed and depressed *Vula*, hanging from the middle gristle of the nose, being filled with a Phlegmaticke and viscid humor. This in expiration hangs out of the Nose, but is drawne in and hid by inspiration; it makes one snaffle in their speech and snort in their sleepe. The second, hath hard flesh, bred of Melancholy blood without adusion, which obstructing the nostrils intercepts the respiration made by that part. The third, is flesh hanging from the Gristle, round, and soft, being the off-spring

spring of Phlegmaticke blood. The fourth is an hard Tumor, like flesh, which when it is touched yeelds a sound like a stone; it is generated of Melancholike blood dried, being somewhat of the nature of a *Scirrhus* confirmed and without paine.

The fifth is as it were composed of many cancrus ulcers spread over the transverse surface of the gristle.

Of all these sorts of *Polypi*, some are not ulcerated; others ulcerated, which send forth a stinking and strong smelling filth. Such of them as are painefull, hard, resisting, and which have a livide, or leaden colour, must not be touched with the hand, because they savour of the Nature of a *Cancer*, as into which they oft degenerate; yet by reason of the paine which oppresses more violently, you may use the *Anodyne* medicines formerly described in a *Cancer*, such as this following.

R. Olei de vitell. ovorum ℥ij, *Lytharg. auri*, & *Tuthia* *prep. an.* ℥j. *succi plant.* *& solani* *an.* ℥℥j. *Lapid. hamatit.* & *camphora*, *an.* ℥℥. Let them be wrought a long time in a leaden mortar, and so make a medicine to be put into the nostrills. Those which are soft, loose and without paine, are sometimes curable, being plucked away with an instrument made for that purpose, or else wasted by actual cauteries put in through a pipe, so that they touch not the sound part; or by potential cauteries, as *Agyptiacum* composed of equal parts of all the simples with vitrioll which hath a facultie to waste such like flesh. *Aquafortis* and oyle of vitrioll have the same facultie, for these take away a *Polypus* by the rootes; for if any part thereof remaine it will breede againe. But Cauteries and acride medicines must be put into the nostrills with this Caution, that in the meane time cold repelling and astringent medicines be applied to the nose and parts about it to assuage the paine, and hinder the inflammation. Such as are *Vnguentum de bolo*, and *vnguentum nutritum*, whites of Egges beate with Rose leaves, and many other things of the like nature.

Which of them admit no manuell operation.

An Anodyne.

Why it must be taken cleare away.

CHAP. III.

Of the Parotides that is, Certaine swellings about the Eares.

THe *Parotis* is a Tumor against nature, affecting the Glandules and those parts seated behind and about the Eares, which are called the Emunctories of the braine; for these because they are loose and spongy, are fit to receive the excrements thereof. Of these some are critically, the matter of the disease somewhat digested being sent thither by the force of nature. Others Symptomaticall, the excrements of the braine increased in quantity or quality rushing thither of their owne accord. Such abscesses often have great inflammation joyned with them, because the byting humor which flowes thither is more vitiated in quality than in quantity. Besides also they often cause great paine, by reason of the distention of the parts indued with most exquisit sence, as also by reason of a Nerve of the fifth Conjugation spread over these parts; as also of the neighbouring membranes of the braine, by which meanes the patient is troubled with the Head-ach and all his face becomes swolne. Yet many times this kinde of Tumor useth to be rayfed by a tough, viscus, and grosse humor.

What it is.

The differences, Their signes and Symptomes.

This disease doth more grievously afflict young men than olde; it commonly brings a Feaver and watching. It is difficult to be cured, especially when it is caused by a grosse, tough, and viscid humor, sent thither by the *Crisis*.

Prognosticks.

The cure must be performed by diet, which must be contrary to the quality of the humor in the temper & consistence of the meates. If the inflammation & rednesse be great, which

The cure.

Lib. 3. de comp.
med. sec. Locos.
Hip. aph. 2 I
lib. I.

which indicate abundance of blood, Phlebotomie will be profitable, yea very necessary. But here we must not use the like judgement in application of locall medicines as we doe in others tumors, as *Galen* admonisheth us; that is, wee must not use repercussives at the beginning, especially if the abscesse be critically; for so, we should infringe or foreflow the indeavors of nature forcibly freeing it selfe from the morbi-
fique matter. But wee must much lesse repell or drive it backe if the matter which hath flowed thither be venenate, for so the reflow thereof to the noble parts would prove mortall. Wherefore the Chirurgion shall rather assist nature in attracting and drawing forth that humor. Yet if the defluxion shall be so violent, if the paine so fierce that thence there may be feare of watchings and a Feaver, which may deject the powers, *Galen* thinks it will be expedient with many resolving medicines to mix some repelling. Wherefore at the beginning let such a Cataplasme be applyed.

Rx. Far. bord. & sem. lin. ana. ʒij. coquantur cum malsa aut decocto cham. addendo but. recen. & olei cham. ana ʒj. fiat Cataplasma. And the following oyntment wil also be good.

Gentle resol-
ving medicines

Rx. But. recen. ʒij, olei cham. & lilior. an. ʒj. unguen. de Althea ʒʒ. cera parum: make an oyntment to be applyed with moist and greasie wooll to mitigate the paine, also somewhat more strong discussing and resolving medicins will be profitable, as :

Stronger re-
solvers.

Rx. Rad. althea & bryon. an. ʒij. fol. ruta, puleg. orig. an. m. j. flo. chamem. melil. an. p. j. coquantur in hydromelite, pistentur, traiciantur, addendo farin. fannagrac. orobi, an. ʒj. pul. Ireos, cham. melilot. an. ʒij. olei aneth. rutac. an. ʒj. fiat cataplasma. But if you determine to resolve it any more, you may use *Emplastrum Oxycroceum* & *Melilot-Plaster*. If the humor doth there concrete and grow hard, you must betake you to the medicines which were prescribed in the Chapter of the *Scirrhus*; but if it tend to suppuration, you shall apply the following medicine.

A Ripening
medicine.

Rx. Rad. liliorum & ceparum sub cineribus coct. an. ʒiij. Vitell. ovor. num. ij. axung. suilla & unguent. basilicon, an. ʒj. far. sem. lini ʒij. fiat Cataplasma. But if the matter doe so require, let the tumor be opened as we have formerly prescribed.

CHAP. III.

Of the Epulis, or overgrowing of the flesh of the Gums.

What it is.

The *Epulis* is a fleshy excrescence of the Gums betweene the teeth, which is by litle and litle oft times encreased to the bignes of an Egge, so that it both hinders the speach and eating; it casts forth salivous and stincking filth, and not seldome degenerates into a *Cancer*, which you may understand by the propriety of the colour, paine and other accidents; for then you must by no meanes touch it with your hand. But that which doth not torment the Patient with paine, may be pluckt away; and let this be the manner thereof.

The Sym-
tomes.

Let it be tyed with a double thred, which must be straiter twitched untill such time as it fall off; when it shall fall away, the place must be burnt with a cautery put through a trunke or pipe, or with *Aqua fortis*, or oyle of *Vitrioll*, but with great care that the sound parts adjoyning thereto be not hurt, for if so be that it be not burnt, it usually returnes.

The Chirur-
gicall cure.

I have often by this meanes taken away such large tumors of this kinde, that they hung out of the mouth in no small bignes, to the great disfiguring of the face, which when as no Chirurgion durst touch, because the flesh looked livide, I ventured upon because they were free from paine; and by taking them away and cauterizing the place, I perfectly healed them; not truly sodainly and at once; for although I burnt the place after dissection; yet neverthelesse they sprung up againe, because a certaine portion of the bone and sockets in which the Teeth stand fastened, were become rotten I have often observed such like flesh by continuance of time to have turned into a gristlely & bony substance. Wherefore the cure must be begun as speedily as may be; for being but litle, and having fastened no deepe roots, it is more easily taken away, being then only filled with a viscid humor, which in successe of time is hardened, and makes the taking away thereof more difficult.

Why the cure
must not be
deferred.

CHAP. V.

Of the Ranula.

Here is oft times a tumor under the tongue, which takes away the liberty of pronuntiatio, or speech; wherefore the Greeks call it *Batrachium*, the Latines *Ranula*, because such as have this disease of the tongue, seeme to expresse their minds by croaking rather than by speaking.

The Reason why it is so called.

It is caused by the falling downe of a cold, moiste, grosse, tough viscid and Phlegmaticke matter, from the braine upon the tongue, which matter in colour and consistence resembles the white of an egge, yet sometimes it lookes of a Citrine or yellowish colour.

The Cause.

That you may safely performe the cure, you must open the Tumor rather with a cautery or hot Iron, than with a Knife, for otherwise it will returne againe. The manner of opening of it must be thus. You shall get a bended hollow and perforated iron plate with a hole in the midst, and making the patient to hold open his mouth, you shall so fit it, that the hole may be upon the part which must be opened. Then there you must open it with an hot Iron, for so you shall hurt no part of the mouth which is whole; but when you are ready to burne it, by thrusting your thumbs under the Patients Chin, you may somewhat elevate the Tumor, whereby you may open it with more certainty; when it is opened you must thrust out the matter contained therein, and then wash the patients mouth with some barley water, hony, and Sugar of Roses; for so the ulcer will be safely and quickly healed.

The Cure.

The deliniation of the Iron plate and crooked actuell Cautery.

CHAP. VI.

Of the swelling of the Glandules, or Almonds of the Throate.

Nature at the jawes neare the roots of the Tongue, hath placed two Glandules opposite to one another; in figure and magnitude like to Almonds, whence also they have their name, Their office is to receive the spittle falling downe from the braine, both least that the too violent falling downe of the humor should hinder the tongue in speaking, as also that the tongue might alwayes have moisture, as it were laid up in store, lest by continuall speaking it should grow dry and faile. For thus this spittle being consumed by feaverish heats, the patients are scarce able to speake, unlesse they first moisten their tongue by much washing of their mouth.

Why the Glandules are called Almonds.

Their use.

These Glandules because they are seated in an hot and moist place, are very subject to inflammations; for there flowes into these oft times together with the blood, a great quantity of crude, phlegmaticke and viscous humors, whence arises a tumor;

The Cause of their tumor.

which

which is not feldome occasioned by drinking much and that vaporous wine, by too much Gluttony, and staying abroad in the open aire.

Symptomes.

Swallowing is painfull and troublesome to the Patient, and commonly hee hath a Feaver. Oft times the neighbouring Muscles of the Throtle and necke are so swolne together with these Glandules, that (as it usually happens in the *Squinzye*) the passage of the breath and aire is stopped, and the Patient strangled.

Cure.

We resist this imminent danger by purging and blood-letting, by applying Cupping-Glasses to the Necke and shoulders, by frictions and ligatures of the extreme parts, and by washing and gargling the mouth and throate with astringent gargarismes. But if they come to suppuration, you must with your incision Knife make way for the evacuation of the Pus, or Matter; but if on the contrary, these things performed according to art, defluxion be encreased, and there is present danger of death by stopping and intercepting the breath, for the shunning so great and imminent danger, the top or upper part of the *Aspera arteria* or Weazon must be opened, in that place where it uses to stand most out; & it may be done so much the safer, because the jugular veines, and arteryes are furthest distant from this place, and for that this place hath commonly litle flesh upon it. And that the incision may be the fityer made, the patient must be wished to bend his head backe, that so the Artery may be the more easily come to by the instrument; then you shal make an incision overtwhart with a crooked knife betweene two rings (not hurting nor touching the Gristlely substance) that is to say, the membrane which tyes together the Gristlely rings being onely cut; you shal then judge that you have made the incision large enough, when you shal perceive the breath to breake out by the wound; the wound must be kept open so long, untill the danger of suffocation be past; and then it must be sowed up not touching the Gristle: But if the lipps of the wound shal be hard and callous, they must be lightly scarified, that so they may become bloody for their easier agglutination and union, as we shall shew more at large in the cure of Hare lips. I have had many in cure, who have recovered, that have had their Weazon together with the Gristlely rings thereof cut with a great wound, as we shall note when wee shal cometo treate of the cure of the wounds of that part.

Extreme diseases must have extreme remedies.

How you must open the Weazon.

CHAP. VII.

Of the inflammation and relaxation of the Vvula, or Columella.

What the Vvula is, and what the use therof. The Cause of the swelling thereof.

He *Vvula* is a litle body, spongy and somewhat sharpened to the forme of a pine apple, hanging even downe from the upper and inner part of the palat, so to breake the force of the Aire drawn in, in breathing and carryed to the Lungs, and to be as a quill to forme and tune the voyce. It often growes above measure by receiving moysture falling downe from the braine, becoming sharpe by litle and litle from a broader and more swolne Basis. Which thing causes many Symptomes; for by the continuall irritation of the distilling humor the Cough is caused, which also hinders the sleepe, and intercepts the liberty of speech; but also by hindring respiration the patients cannot sleepe unlesse with open mouth: they are exercised with a vaine endeavoring to swallow (having as it were a morsell sticking in their jawes) and are in danger of being strangled.

Symptomes.

The Cure.

This disease must be resisted and assailed by purging, bleeding, Cupping, taking of chyfters, using astringent Gargles, and a convenient diet; but if it cannot thus be overcome, the cure must be tryed by a causticke of *Aqua fortis*, which I have divers times done with good successe. But if it cannot be so done, it will be better to put to your hand, than through idlenesse to suffer the patient to remaine in imminent and deadly danger of strangling; yet in this there must very great caution be used; for the Chirurgion shal not judge the *Vvula* fit to be touched with an instrument or caustick, which is swolne with much enflamed, or blacke blood after the manner of a *Cancer*; but hee shal boldly put to his hand if it be longish, grow small by litle and litle into a sharpe, loose & soft point; if it be neither exceeding red, neither swolne with too much blood

The Cure by Chirurgery.

but

but whitish and without paine. Therefore that you may more easly and safely cut away, that which redounds and is superfluous, desire the patient to sit in a light place, and hold his mouth open; then take hold of the top of the *Vvula* with your fingers, and cut away as much thereof as shall be thought unprofitable. Otherwise you shall binde it with the instrument here under described; the invention of this instrument is to be ascribed to *Honoratus Tastellanus* that diligent and learned man, the Kings Physition in ordinary, and the chiefe Physition of the Queene mother; Which also may be used in binding of *Polypi* and warts in the necke of the Wombe.

The Deliniation of constrictory rings fit to twitch, or binde the Columella, with a twisted thred.

- A. Shewes the ring whose upper part is somewhat hollow.
 B. A double waxed thred, which is couched in the hollownesse of the ring, and hath a running, or loose knot upon it.
 C. An iron rod, into the eye whereof the fore-mentioned double thred is put, and it is to twitch the *Columella* when as much thereof is taken hold of, as is unprofitable, and so to take it away without any fluxe of blood. When you would straiten the thred, draw it againe through this iron rod, and so straine it as much as you shall thinke good, letting the end of the thred, hang out of the mouth. But every day it must be twitched harder than other, untill it fall away by meanes thereof, and so the part and patient be restored to health. I have deliniated three of these instruments, that you may use which you will, as occasion shall be offered.

A Figure of the Speculum oris, by which the mouth is held and kept open, whilest the Chirurgion is busied in the cutting away or binding the Vvula.

But if an eating ulcer shall associate this relaxation of the *Vvula*, together with a fluxe

fluxe of blood, then it must be burnt and seared with an hot iron, so thrust into a Trunke, or Pipe with an hole in it, that no sound part of the mouth may be offended therewith.

A hollow Trunke with a hole in the side, with the hot iron inserted, or put therein.

CHAP. VIII.

Of the Angina, or Squinzy.

What it is.

The differences.
The first kind.

The Sym-
ptomes.

He Squinancy, or Squinzy, is a swelling of the jawes, which hinders the entring of the ambient aire into the weazon, and the vapours and spirit from passage forth, and the meate also from being swallowed. There are three differences thereof. The first torments the patient with great paine, no swelling being outwardly apparent, by reason the morbidicke humor lyes hid behinde the almonds or Glandules at the *Vertebra* of the necke, so that it cannot be perceived, unlesse you hold downe the tongue with a spatula or the *Speculum oris*, for so you may see the rednesse and tumor ther e lying hid. The patient cannot draw his breath, nor swallow downe meate, nor drinke; his tongue, (like a Gray-hounds after a course,) hangs out of his mouth, and he holds his mouth open that so hee may the more easily draw his breath; to conclude, his voyce is as it were drownd in his jawes and nose; he cannot lye upon his backe, but lying is forced to sit, so to breathe more freely: and because the passage is stoppt, the drinke flies out at his nose; the eyes are fiery and swollen, and standing out of their orbe. Those which are thus affected are often suddainely suffocated, a foame rising about their mouthes.

The second
kinde.

The second difference is said to be that, in which the tumor appeares inwardly, but litle or scarce any thing at all outwardly, the tongue, Glandules, and jawes appearing somewhat swollen.

The third.

The third being least dangerous of them all, causes a great swelling outwardly, but litle inwardly.

The Cause.

The Causes are either internall, or externall. The externall are a stroake, splinter or the like things sticking in the Throat, or the excesse of extreme cold, or heat. The internall causes are a more plentifull defluxion of the humors either from the whole body or the braine, which participate of the nature either of blood, choler or flegme, but seldome of Melancholy. The signes by which the kinde and commixture may be knowne, have beene declared in the generall treatise of tumors. The Squinzy is more dangerous, by how much the humor is lesse apparent within and without. That is lesse dangerous which shewes it selfe outwardly, because such an one shuts not up the wayes of the meate, nor breath. Some dye of a Squinzy in twelue houres others in two, foure or seven daies. Those (saith *Hippocrates*) which scape the Squinzy, the disease passes to the lungs, and they dye within seven dayes;

dayes; but if they scape these dayes, they are suppurated; but also often times this kind of disease is terminated by disappearing, that is, by an obscure reflux of the humor into some noble part, as into the Lungs (whence the *Empyema* proceeds) and into other principall parts, whose violating brings inevitable death; sometimes by resolution, otherwise by suppuration.

The way of Resolution is the more to be desired; it happens when the matter is small, and that subtle, especially if the Physitian shall draw blood by opening a veine, and the patient use fitting Gargarismes. A Criticall Squincy divers times proves deadly by reason of the great falling downe of the humor upon the throte, by which the passage of the breath is sodainely shut up. Brothes must be used made with Capons, and Veale, seasoned with Lettuce, Purslaine, Sorrell, and the cold seeds.

If the Patient shall be somewhat weake, let him have potched Egges, and Barly ^{Diet.} Creames, the Barly being first boiled with Raisons in water and Sugar, and other meates of this kinde. Let him be forbidden wine, in stead whereof he may use *Hydromelita*, and *Hydrosachara* (that is, drinckes made of water and Hony, or water and Sugar) as also the Syrupes of dried Roses, of Violets, Sorrell and Limons, and others of this kinde. Let him avoide too much sleepe. But in the meane time the Physitian must be carefull of all, because this disease is of their kinde, which brooke no delays. Wherefore let the *Basilica* be presently opened, on that side the tumor is the greater; then within a short time after the same day, for evacuation of the conjunct matter, let the veine under the tongue be opened; let cupping-Glasses be applyed, sometimes with scarification, sometimes without, to the necke and shoulders, and let frictions and painefull Ligatures be used to the extreme parts. But let the humor impact in the part be drawne away by glisters and sharpe suppositories. Whilest the matter is in defluxion, let the mouth without delay be washed with astringent gargarismes to hinder the defluxion of the humor, least by its suddaine falling downe it kill the Patient, as it often happens, all the Physitions care and diligence notwithstanding. Therefore let the mouth be frequently washed with Oxy- ^{Repelling} crate, or such a gargarisme: *R. Pomorum silvest. nu. iiii. sumach, Rofar. rub. an. m. ss. berber. ʒij.* let them be all boyled with sufficient quantity of water to the consumption of the halfe, adding thereunto of the wine of soure Pomegranats ʒiiij. of *diamoron* ʒij, let it be a litle more boyled and make a gargle according to arte. And there may be other Gargarismes made of the waters of Plantaine, Night-shade, Verjuice, Iulep of Roses and the like. But if the matter of the defluxion shall be Phlegmaticke, Alume, Pomgranate pill, Cypresse nuts, and a litle Vinegar may be safely added. But on the contrary, repercussives must not be outwardly applyed, but rather Lenitives, whereby the external parts may be relaxed and rarified, and so the way be open either for the diffusing or resolving the portion of the humor. You shall know the humor to begin to be resolved, if the Feaver leave the patient, if he swallow, speake and breathe more freely, if he sleepe quietly, and the paine begin to be much awaged. Therefore then natures endeavor must be helped by applying resolving medicines, or else by using suppuratives inwardly and outwardly, if the matter seeme to turne into *Pus*. Therefore let gargarismes be made of the roots ^{Ripening} of March-Mallowes, Figgs, Iujubes, damaske Prunes, Dates, perfectly boyled in water. The like benefit may be had by Gargarismes of Cowes milke with Sugar, by oyle of sweete Almonds, or Violets warme, for such things helpe forward suppuration and aswage paine; let suppurating cataplasmes be applyed outwardly to the necke and throate, and the parts be wrapped with wooll moistened with oyle of Lillyes. When the Physitian shall perceive that the humor is perfectly turned into *Pus*, let the patients mouth be opened with the *Speculum oris*, and the abscesse opened with a crooked and long incision knife; then let the mouth be now and then washed with clensing gargles; as *R. Aqua horde ʒ lib. ss. mellis ros. ʒj. syr. rosar. sic. an ʒj. fiat gargarisma.* Also the use of *anamel*, that is wine, and Hony will be fit for this purpose. The ulcer being clensed by these means, let it be cicatrized with a litle roch-Alume added to the former gargarismes. ^{Dezergent}

The Figure of an incision knife opened out of the haffe, which serves for a sheath thereto.

CHAP. IX.

Of the Bronchocele, or Rupture of the throate.

The reason of the name.

That which the French call Goetra, that the Greeks call *Bronchocele*, the Latines *Gutturis Hernia*, that is, the Rupture of the throate. For it is a round tumor of the throate, the matter wherof comming from within outwards, is contained betweene the skin and weazon; it proceeds in weomen from the same cause as an *Aneurisma*.

The differences.

But this generall name of *Bronchocele* undergoes many differences; for sometimes it retaines the nature of *Melicerides*, other whiles of *Steatomas*, *Atheromas* or *Aneurismas*, in some there is found a fleshy substance having some small paine; some of these are small, others so great, that they seeme almost to cover all the throate; some have a *Cyste*, or bagge, others have no such thing; all how many so ever they be, and what end they shall have, may be knowne by their proper signes; these which shall be cureable, may be opened with an actuall or potentiall cautery, or with an incision knife. Hence if it be possible, let the matter be presently evacuated, but if it cannot be done at once, let it be performed at diverse times, and discussed by fit remedies, and lastly let the ulcer be consolidated and cicatrized.

The Cure.

CHAP. X.

Of the Pleurisie.

What it is.

The Pleurisie is an inflammation of the membrane, investing the ribbes, caused by subtil and cholericke blood, springing upwards with great violence from the hollow veine into the *Azygos*, and thence into the intercostall veines, & is at length powred forth into the emptie spaces of the intercostall muscles, and the mentioned membrane. Being contained there, if it tend to suppuration, it commonly infers a pricking paine, a Feaver and difficulty of breathing. This suppurated blood is purged and evacuated one while by the mouth; the Lungs sucking it, and so casting it into the Weazon, and so into the mouth, otherwhiles by urine, and sometimes by stoole.

Of a Pleurisie comming to suppuration.

Of the change thereof into an *Empyema*.

Of the apertion of the side in an *Empyema*.

But if nature being too weake, cannot expectorate the purulent blood poured forth into the capacity of the Chest the disease is turned into an *Empyema*, wherefore the Chirurgion must then be called, who beginning to reckon from below upwards, may make a vent betweene the third and fourth true and legitimate ribs; & that must be done either with an actuall or potentiall cautery, or with a sharpe knife drawne upwards towards the backe, but not downwards, lest the vessells should be violated which are disseminated under the rib. This apertion may be safely and easily performed by this actuall cautery; it is perforated with foure holes, through one whereof there is a pin put higher or lower according to the depth & manner of your incision:

the

then the point thereof is thrust through a plate of iron perforated also in the midst, into the part designed by the Physitian, lest the wavering hand might peradventure touch, and so hurt the other parts not to be medled withall. This same plate must be somewhat hollowed, that so it might be more easily fitted to the gibbous side, and bound by the corners on the contrary side with foure strings. Wherefore I have thought good here to expresse the figures thereof.

The Figure of an actual cantery with its plate fit to be
used in a pleurisie.

But if the patient shall have a large body, Chest and ribs, you may divide and perforate the ribs themselves with a Trepan; howsoever the apertion be made, the pus or matter must be evacuated by little and little at severall times; and the capacity of the Chest clenched from the purulent matter by a detergent injection of vj ounces of Barly water, and ʒij hony of Roses, and other the like things mentioned at large in our cure of wounds.

CHAP. XI.

Of the Dropsie.

HE Dropsie is a Tumor against nature by the aboumdance of a waterish humor, of flatulencies, or Phlegme, gathered one while in all the habite of the body, otherwhiles in some part, and that especially in the capacity of the belly betweene the *Peritonaum* and entrailes. From this distinction of places and matters there arise divers kinds of Dropsies.

First that Dropsie which fills that space of the belly, is either moist or dry. The moist is called the *Ascites*, by reason of the similitude it hath with a leather bottle, or *Borachio*, because the waterish humor is contained in that capacity, as it were in such a vessell.

The dry is called the *Tympanites*, or Timpany, by reason the belly swolne with winde, sounds like a (*Tympanum*) that is, a Drum. But when the whole habit of the body is distended with a Phlegmaticke humor, it is called *Anasarca* or *Leucophlegmatia*. In this last kinde of Dropsie the lower parts first swell, as which by reason of their site are more subject to receive defluxions, and more remote from the fountaine of the native heate; wherefore if you presse them downe, the print of your finger will remaine sometime after; the patients face will become pale and puffed up, whereby it may be distinguished from the two other kinds of Dropsie. For in them first the belly, then by a certaine consequence the thighes and feet doe swell. There are besides also particular Dropsies contained in the strait bounds of certaine places, such are the *Hydrocephalos* in the head; the *Bronchochele* in the throat; the *Pleurocele* in the Chest; the *Hydrocele* in the *Scrotum*, or Cod; and so of the rest. Yet they all arise from the same cause; that is, the weaknesse or defect of

What the
Dropsie is.

The differ-
ences thereof.

The Symp-
tomes.

The Causes.

the

How divers
diseases turne
into Dropsies.

the altering or concocting faculties, especially of the liver, which hath beene caused by a *Scyrrhus*, or any kinde of great distemper, chiefly cold, whether it happen primarily, or secondarily by reason of some hote distemper dissipating the native and inbred heate, such a Dropsie is uncureable; or else it comes by consent of some other higher or lower part; for if in the Lungs, Midriffe, or Reines there be any distemper, or disease bred, it is easily communicated to the gibbous part of the Liver by the branches of the hollow veine, which runnethither. But if the milchie proceed from the Spleene, Stomacke, Mesentery, Guts, especially the *jejunum* and *Ileum*, it creeps into the hollow side of the Liver by the meseraicke veines, and other branches of the *Vena porta* or Gate-veine. For thus such as are troubled with the *Asthma*, ptisicke, Spleene, Jaundise, and also the Phrensie, fall into a Dropsie.

The signes of
an *Ascites*.

The Symptoms.

Lastly, all such as have the menstruall or hæmorrhoid all blood suppressed or too immoderately flowing contrary to their custome, ei her overwhelmes, diminisheth or extinguisheth the native heate; no otherwise than fire, which is suffocated by too great a quantity of wood; or dieth and is extinguished for want thereof. We must looke for the same from the excrements of the belly or bladder, cast forth either too sparingly or too immoderately: Or by too large quantity of meates too cold, and rashly devoured without any order; To conclude by every default of externall causes, through which occasion, error may happen, in diet or exercise.

The *Ascites* is distinguished from the two other kinds of Dropsies, both by the magnitude of the efficient cause, as also by the violence of the Symptomes, as the dejected appetite, thirst, and swelling of the *Abdomen*. And also when the body is moved or turned upon either side, you may heare a sound as of the jogging of water in a vessell halfe full. Lastly the humor is diversely driven upwards or downewards, according to the turning of the body and compression of the *Abdomen*; It also causeth various Symptomes by pressure of the parts to which it floweth. For it causeth difficultie of breathing and the cough by pressing the Midriffe; by sweating through into the capacity of the Chest it causeth like Symptomes as the *Empyema*. Besides also the Patients often seeme, as it were, by the ebbing and flowing of the waterish humor, one while to be carryed to the skies, and another whiles to be drowned in the water, which I have learnt not by reading of any author, but by the report of the patients themselves. But if these waterish humors be fallen downe to the lower parts, they suppress the excrements of the Guts and bladder by pressing & straitning the passages. When the patient lies on his backe the tumor seemes lesse, because it is spread on both sides; On the contrary when hee stands or sits, it seemes greater, for that all the humor is forced or driven into the lower belly, whence hee feelles a heavines in the *Pecten* or share. The upper parts of the body fall away by defect of the blood fit for nourishment in quality and consistence; but the lower parts swell by the flowing downe of the Serous and watrish humor to them. The pulse is little, quicke, and hard with tention.

Prognostickes.

This disease is of the kinde of Chronicall or long diseases; wherefore it is scarce, or never cured, especially in those who have it from their mothers wombe, who have the Action of their Stomacke depraved, and those who are cachecticke, old, and lastly all such as have the naturall facultie languishing and faultie.

On the contrary young and strong men, especially if they have no Feaver, and finally all who can endure labour and those exercises which are fit for curing this disease, easily recover, principally if they use a Physition before the water which is gathered together doe putrefie and infect the bowells by its contagion.

CHAP. XII.

Of the cure of the Dropsie.

THe beginning of the cure must be with gentle and milde medicines; neither must we come to a *Paracentesis*, unlessse we have formerly used and tried these. Therefore it shall be the part of the Physition to prescribe a drying diet, and such medicines as carry away water, both by stoole and urine. *Hippocrates* ordaines this powder for Hydropicke persons. R, *Canthar. ablati* Hip. lib. 3. de acut. & lib. de intern. *capiti. & alis* ʒss. *Comburentur in furno, & fiat pulvis*; of which administer two graines in white wine, for nature helped by this, and the like remedies hath not seldome beene seene to have cured the dropsie. But that we may hasten the cure, it will be availeable to stirre up the native heate of the part by application of those medicines which have a discussing force: as bagges, baths, ointments, and emplaisters. Bagges. Let bagges be made of drie and harsh Bran, Oates, Salt, Sulphure, being made hot, or for want of them, of Sander, or Ashes often heated.

The more effectuall baths are salt, nitrous, and sulphurous waters, whether by Bathes. Nature or Art, that is, prepared by the dissolution of Salt niter, and Sulphur; to which, if Rue, Marjarom, the leaves of Fennell, and tops of Dill, of *Stachas*, and the like be added, the businesse will goe better forwards. Let the ointments be made Liniments of the oyles of Rue, Dill, Baies, and Squills, in which some *Euphorbium*, Pellitory of Spaine, or Pepper have beene boyled. Let plaisters be made of Franckinsence, Emplaisters, Myrrhe, Turpentine, *Costus*, Baiberies, English galengall, hony, the dung of Oxen, Pigeons, Goats, Horses, and the like, which also may be applied by themselves. If the disease continue, we must come to *Synapismes* and *Phenigmes*, that is, to rubrifying Vesicatories, and vesicatory medicines. When the blisters are raised, they must be annointed againe, that so the water may by little and little flow so long untill all the humor be exhausted, and the patient restored to health.

Galen writes, the Husbandmen in *Asia*, when they carried wheat out of the country into the city in Carrs, when they will steale away and not be taken, hidde some Gal. lib. de facul. natur. 1. stone jugs fild with water in the midst of the wheat; for that will draw the moisture through the jugs into it selfe, and increase both the quantitie and weight. When certaine pragmaticall Physitions had read this, they thought that wheat had force to draw out the water, so that if any sicke of the Dropsie should be buried in a heape of wheat, it would draw out all the water.

But if the Physition shall profit nothing by these meanes, he must come to the exquisitely chiefe remedy, that is, to *Paracentesis*. Of which because the opinions of the ancient Physitions have beene divers, we will produce and explaine them. Divers opinions of Paracentesis, or opening of the belly. Reasons against it.

Those therefore which disallow *Paracentesis*, conclude it dangerous for three reasons. The first is, because by powring out the contained water, together with it, you dissipate and resolve the spirits, and consequently the naturall, vitall, and animall faculties; another opinion is, because the Liver wanting the water by which formerly it was borne up; thence forward hanging downe by its weight, depresseth and draweth downewards the Midriffe and the whole Chest, whence a drie cough, and a difficulty of breathing proceede. The third is, because the substance of the *Peritonæum*, as that which is nervous, cannot be pricked or cut without danger, neither can that which is pricked or cut be easily agglutinated and united, by reason of the spermaticque and bloudlesse nature thereof. *Erasistratus* moved by these reasons condemned *Paracentesis* as deadly: also he perswaded that it was unprofitable for these following reasons, *viz.* because the water powred forth, doth not take away with it the cause of the Dropsie, and the distemper and hardnesse of the Liver, and of the other bowels, whereby it comes to passe that by breeding new waters they may easily againe fall into the Dropsie. And then the feaver, thirst, the hot and drie distemper of the bowels, all which were mitigated by the touch of the included water, are aggravated by the absence thereof, being powred forth: which thing seemeth to have moved *Avicen* and *Gordonius* that he said none; the other said very few lived after the *Paracentesis*: but the refutation of all such reasons is very easie. Erasistratus his Reasons against it.

Reasons for it.

For, for the first *Galen* inferres, that harmefull diffipation of spirits, and resolving the faculties happens, when the *Paracentesis* is not diligently, and artificially performed. As in which the water is presently powred forth; truly if that reason have any validity, *Phlebotomy* must seeme to be removed farre from the number of wholesome remedies, as whereby the bloud is powred forth, which hath farre more pure and subtile spirits, than those which are said to be diffused and mixed with the Dropsie-waters.

Lib. 3. Cap. 21.

But that danger which the second reason threatens shall easily be avoided; the patient being desired to lie upon his backe in his bed, for so the Liver will not hang downe. But for the third reason, the feare of pricking the *Peritoneum*, is childish: for those evils which follow upon wounds of the nervous parts, happen by reason of the exquisite sence of the part, which in the *Peritoneum* ill affected and altered by the contained water, is either none or very small. But reason and experience teach, many nervous parts, also the very membranes themselves being farre removed from a fleshie substance, being wounded, admit cure; certainly much more the *Peritoneum*, as that which adheres so straitly to the muscles of the *Abdomen*, that the dissector cannot separate it from the flesh, but with much labour. But the reason which seemes to argue the unprofitableness of the *Paracentesis* is refelled by the authority of *Celsus*. I, saith he, am not ignorant that *Erasisstratus* did not like *Paracentesis*; for he thought the Dropsie to be a disease of the Liver, and so that it must be cured, and that the water was in vaine let forth, which the Liver being vitiated, might grow againe. But first this is not the fault of this bowell alone, and then although the water had his originall from the Liver, yet unlesse the water which staieth there contrary to nature being evacuated, it hurteth both the Liver, and the rest of the inner parts, whilest it either encreaseth their hardnesse, or at the least keepeth it hard, and yet notwithstanding it is fit the body be cured. And although the once letting forth of the humor profit nothing, yet it make way for medicines, which while it was there contained, it hindered. But this serous, salt, and corrupt humor, is so farre from being able to mitigate a Feaver and thirst, that on the contrary, it encreaseth them. And also it augmenteth the cold distemper, whilest by its abundance it overwhelmes and extinguisheth the native heate. But the authority of *Calius Aurelianus* that most noble Phisition, though a Methodicke, may satisfie *Avicen* and *Gordonius*. They, saith he, which dare avouch that all such as have the water let out by opening their belly have died, doe lie; for we have seene many recover by this kind of remedy: but if any died, it happened either by the default of the flow or negligent administration of the *Paracentesis*. I will adde this one thing which may take away all error of controversies: we unwisely doubt of the remedy when the patient is brought to that necessity, that we can onely helpe him by that meanes. Now must we shew how the belly ought to be opened. If the Dropsie happen by fault of the Liver, the section must be made on the left side; but if of the Splene, in the right: for if the patient should lie upon the side which is opened, the paine of the wound would continually trouble him, and the water running into that part where the section is, would continually droppe, whence would follow a dissolution of the faculties. The Section must be made three fingers bredth below the Navell, to wit, at the side of the right muscle, but not upon that which they call the *Linea Alba*; neither upon the nervous parts of the rest of the muscles of the *Epigastrium*; that so we may prevent paine and difficulty of healing. Therefore wee must have a care that the patient lie upon his right side, if the incision be made in the left, or on the left, if on the right. Then the Chirurgion both with his owne hand, as also with the hand of his servant assisting him, must take up the skinne of the belly, with the fleshie pannicle lying under it, and separate them from the rest; then let him divide them so separated with a Section even to the flesh lying under them, which being done, let him force as much as hee can the devided skinne upwards towards the stomacke, that when the wound, which must presently be made in the flesh lying there under, shall be consolidated, the skinne by its falling therein, may serve for that purpose: then therefore let him divide the musculous flesh and *Peritoneum* with a small wound, not hurting the Kall or Guts.

the parts
chiefely affec-
ted,

The manner
of making
apertion,

Then

Then put into the wound a trunke, or golden, or silver crooked pipe, of the thicknesse of a Goofes-quill, and of the length of some halfe a finger. Let that part of it which goes into the capacity of the belly have something a broad head, and that perforated with two small holes, by which a string being fastened, it may be bound so about the body, that it cannot be moved, unlesse at the Chirurgions pleasure. Let a sponge be put into the pipe, which may receive the dropping humor: and let it be taken out when you would evacuate the water: but let it not be powred out all together, but by little and little, for feare of dissipation of the spirits, and resolution of the faculties, which I once saw happen to one sicke of the Dropsie. He being impatient of the disease and cure thereof, thrust a Bodkin into his belly, and did much rejoyce at the powring forth of the water, as if he had bin freed from the humor and the disease, but died within a few houres, because the force of the water, running forth, could by no meanes be staied, for the incision was not artificially made. But it will not be sufficient to have made way for the humor by the meanes aforementioned, but also the externall orifice of the pipe must be stopped and strengthened by double cloathes, and a strong ligature, least any of the water flow forth against our wills. But we must note that the pipe is not to be drawne out of the wound, before as much water shall be issued forth as we desire, & the tumor requireth; for once drawne forth, it cannot easily be put in againe, and without force & paine be fitted to the lips of the wound, because the skin and fleshy pannicle cover it by their falling into the wound of the flesh or muscle. But whilst the water is in evacuation, we must have a diligent care of feeding the Patient, as also of his strength, for if that faile, and he seeme to be debilitated, the effusion of the water must be staied for some dayes; which at the length performed according to our desire, the wound must be so consolidated that the Chirurgion beware it degenerate not into a Fistula.

A History.

A Caution for taking out the Pipe,

The Figure of a Pipe in forme of a Quill, to evacuate the water in Dropsies.

Others performe this businesse after another manner; for making an incision, they thrust through the lipps of the wound with a needle and threed: but they take up much of the fleshie substance with the needle, least that which is taken up should be rent and torne by the forcible drawing of the lippes together. Then the threed it selfe is wrapped up and downe over both ends of the needle, so thrust through, as is usually done in a hare-lippe, that so the lippes of the wound may

Another manner of evacuating the water after the operation.

so closely cohere, that not a drop of water may get out against the Chirurgions will. Sometimes such as are cured and healed of the Dropsie, fall into the laundise, whom I usually cure after this manner. R, *sterc. anser.* ʒij, dissolve it in ʒiij, *vini alb. coctar.* make a Potion, and let it be given two houres before meate.

A medicine for the laundies.

CHAP. XIII.

Of the tumor and relaxation of the Navell.

He *Exomphalos* or swelling of the Navell, is caused by the *Peritoneum*, either relaxed or broken: for by this occasion oft-times the Guts, and oft-times the Kall, fall into the seat of the Navell, and sometimes superfluous flesh is there generated; otherwise this tumor is as an *Aneurisma* by too great a quantity of blood powred forth in that place: otherwise by a flatulent matter, and sometimes by a waterish humor. If the humor be occasioned by the Kall, the part it selfe will retaine his proper colour, that is, the colour of the skinn; the tumor will be soft and almost without paine, and which will reside without noise, either by the pressure of your fingers, or of it selfe when the Patient lieth on his backe; but the

The diuers causes thereof.

Signes hereof occasioned by the Kall.

By the guts: tumor caused by the guts, is more unequall, and when it is forced in by the pressure of your fingers, there is such a noise heard, as in the *Enterocoele*; but if the tumor proceede of superfluous flesh, it will be harder and more stubborne, not easily retiring into the body, although the Patient lie upon his backe, and you presse it with your fingers.

By flesh, The tumor is softer which proceeds of winde, but which will not retire into the body, and sounds under your naile like a taber. If the swelling be caused by a waterish humor, it hath all things common with the flatuous tumor, except that it is not so visible, and without noise. If it be from effusion of blood, it is of a livid colour, but if the effused blood shall be arteriall, then there are the signes of an *Aneurisma*.

By winde, Wherefore when the tumor is caused by the Guts, Kall, Winde, or a waterish humor, it is cured by Chirurgery: but not if it proceede from a fleshie excrescence or suffusion of blood. The tumor of the Navell proceeding from the Kall, and Guts, the Patient must lie upon his backe to be cured, and then the Kall, and Guts, must with your fingers be forced into their due place: then the skinne with which the tumor is circumscribed must be taken up with your fingers, and thrust through with a needle, drawing after it a double twined and strong threed; then it must be scarified about the sides, that so it may be the easier agglutinated. Then must it be thrust through with a needle, three or foure times, according to the manner and condition of the distention and tumor. And so twitch it strongly with a threed, that the skinne which is so bound may at length fall off together with the ligatures. But also you may cut off the skinne so distended even to the ligature, and then cicatrize it, as shall be fit. A flatulent tumor of the Navell shall be cured with the same remedies, as we shall hereafter mention in the cure of a windy rupture, but the watery may be powred forth by making a small incision. And the wound shall be kept open, so long, untill all the water be drained forth.

By a waterish humor.
By bruised blood.
Which may be cured by Chirurgery, which not.

The cure by Chirurgery.

CHAP. XIII.

Of the Tumors of the Groines and Codds, called *Herniæ*, that is, *Ruptures*.

There are onely 3. sorts of Ruptures,

He ancient Philistions have made many kindes of Ruptures, yet indeede there are onely three to be called by that name, that is, the *Intestinalis*, or that of the guts, the *Zirbalis*, or that of the kall, and that which is mixed of them both. The other kindes of Ruptures have come into this order, rather by similitude, than any truth of the thing: for in them the Gut, or Kall doe not forsake their places.

Bubonocoele.

Enterocoele and *Epiplocele.*

Hydrocele.
Physocoele.

Sarcocoele.

Cirrococle.

The Causes.

The signes.

The Greekes have given to all these severall names, both from the seat of the tumor, as also from their matter. For thus they have called an unperfect rupture which descends not beyond the Groines, nor falls downe into the Codds, *Bubonocoele*: but the compleate which penetrates into the Codde, if it be by falling downe of the Gut, *Enterocoele*: if from the Kall, *Epiplocele*; if from them both together, they name it *Enterocoele*: but if the tumor proceede from a waterish humor, they terme it *Hydrocele*; if from winde, *Physocoele*, if from both, *Hydrophysocoele*; if a fleshie excrescence shall grow about the testicle, or in the substance thereof, it is named *Sarcocoele*. If the veines interwoven, and divaricated diverse wayes shall be swollen in the Codde and Testicles, the tumor obtaines the name of a *Cirrococle*. But if the humors shall be shut up, or sent thither, the name is imposed upon the tumor, from the predominant humor, as we have noted in the beginning of our Tractate of tumors. The causes are many, as all too violent motions, a stroake, a fall from a high place, vomiting, a cough, leaping, riding upon a trotting horse, the sounding of trumpets, or sackbuts, the carrying, or lifting vp of a heavy burden, racking, also the too immoderate use of viscid and flatulent meates; for all such things may either relaxe or breake the *Peritonæum*, as that which is a thinne and extended membrane. The signes of a *Bubonocoele* are a round tumor in the Groine, which pressed, is easily forced in. The signes of an *Enterocoele*, are a hard tumor in the Codde, which forced, returneth backe and departeth

parteth with a certaine murmour and paine; but the tumor proceeding of the Kall, is laxe and feeles soft like Wooll, and which is more difficultly forced in, than that which proceeds from the Guts, but yet without murmuring and paine: for the substance of the Guts, seeing it is one, and continued to it selfe, they doe not onely mutually succcede each other, but by a certaine consequence doe, as in a dance draw each other, so to avoide distention, which in their membranous body cannot be without paine, by reason of their change of place from that which is naturall, into that against nature: none of all which can befall the Kall, seeing it is a stupide body, and almost without sense, heavy, dull, and immoveable. The signes that the *Peritoneum* is broken, are the sudden increase of the tumor, and a sharpe and cutting paine; for when the *Peritoneum* is onely relaxed, the tumor groweth by little and little, and so consequently with small paine; yet such paine returnes so often, as the tumor is renewed by the falling downe of the Gut, or Kall, which happens not the *Peritoneum* being broken: for the way being once open, and passable to the falling body, the tumor is renewed without any distention, and so without any paine to speake of. The rest of the signes shall be handled in their places. Sometimes it happens that the Guts, and Kall, do so firmly adhere to the proceffe of the *Peritoneum*, that they can not be driven back into their proper seate. This stubborne adhesion happens by the intervention of the viscid matter, or by meanes of some excoriation caused by the rude hand of a Chirurgion, in too violently forcing of the Gut, or Kall, into their place. But also, too long stay of the gut in the codde, and the neglect of wearing a Trusse, may give occasion to such adhesion. A perfect and inveterate rupture by the breaking of the proceffe of the *Peritoneum* in men of full growth, never, or very seldomes admits of cure. But you must note, that by great ruptures of the *Peritoneum*, the Guts may fall into the codde, to the bignesse of a mans head, without much paine and danger of life, because the excrements, as they may easily enter, by reason of the largenesse of the place and rupture, so also they may easily returne.

What rupture
is incurable.

CHAP. XV.

Of the cure of Ruptures.

Because children are very subject to Ruptures, but those truly not fleshy or varicous, but watry, windy, and especially of the Guts, by reason of continuall and painefull crying and coughing: Therefore in the first place we will treat of their cure. Wherefore the Chirurgion, called to restore the Gut which is fallen downe, shall place the child, either on a table, or in a bed, so that his head shall be low, but his buttocks, and thighes higher; then shall he force with his hands by little and little, and gently, the Gut into its proper place; and shall foment the Groine with the astringent fomentation, described in the falling downe of the wombe. Then let him apply this remedy, *R. Praescript. decoctionis quantum sufficit, farinae hordei & fabarum, an. ʒij. pulver. Aloes, Mastiches, Myrryll. & Sarcoco. an. ʒss, Bolz Armeni ʒij.* Let them be incorporated and made a cataplasme according to Art. For the same purpose he may apply *Emplastrum contra Rupturam*: but the chiefe of the cure consists in folded clothes, and Trusses, and ligatures artificially made, that the restored gut may be contained in its place, for which purpose he shall keepe the child seated in his cradle for 30. or 40. dayes, as we mentioned before; and keepe him from crying, shouting, and coughing. *Aetius* bids steepe paper 3. dayes in water, and apply it made into a ball to the groine, the gut being first put up; for that remedy by 3. dayes adhesion will keep it from falling down. But it will be, as I suppose more effectually, if the paper be steeped not in common, but in the astringent water, described in the falling downe of the wombe. Truly I have healed many by the helpe of such remedies, and have delivered them from the hands of Gelders, which are greedy of childrens testicles, by reason of the great gaine they receive from thence. They by a crafty cozenage, perswade the Parents, that the falling downe of the Gut into the Codde, is incurable: which thing notwithstanding, experience convinceth to be false, if so be the cure be performed according to the forementioned manner, when the *Peritoneum* is onely relaxed, and not broken: for the proceffe thereof by which

this cure.

Another me-
dicine.

A notable
History.

the Gut doth fall as in a steepe way, in progresse of time and age is strained and knit together, whilst also in the meane time the guts grow thicker.

A certaine Chirurgion who deserveth credit, hath told me that he hath cured many children as thus: He beates a loadstone into fine powder, and gives it in pappe, and then hee annointes with hony the Groine, by which the gut came out, and then strewed it over with fine filings of iron. He administred this kinde of remedy for ten or twelve dayes: The part, for other things, being bound up with a ligature and ruffe as was fitting. The efficacie of this remedy seemeth to consist in this; that the loadstone by a naturall desire of drawing the iron which is strewed upon the Groine, joynes to it the fleshy and fatty particies interposed betweene them, by a certaine violent impetuosity, which on every side pressing and bending the loosenesse of the *Peritonaeum*, yea verily adjoyning themselves to it, in processe of time by a firme adhesion intercept the passage and falling downe of the Gut or Kall; which may seeme no more abhorring from reason, than that we behold the loadstone it selfe through the thicknesse of a table, to draw iron after it any way. The same Chirurgion affirmed, that he frequently and happily used the following medicine. Hee burnt into ashes in an Oven red Snailles, shut up in an earthen pot, and gave the powder of them to little children in pappe, but to those which were bigger, in broath.

But we must despaire of nothing in this disease, for the cure may happily proceede in men of full growth, as of fortie yeare old, who have filled the three demensions of the body, as this following relation testifies.

There was a certaine Priest in the Parish of Saint *Andrewes*, called *John Moret*, whose office it was to sing an Epistle with a loud voice as often as the solemnitie of the day, and the thing required. Wherefore seeing he was troubled with the *Enterocoele*, he came to me, requiring helpe, saying, he was troubled with a grievous paine, especially then, when he stretched his voice in the Epistle.

The Figure of a man broken on one side, wearing a Trusse, whose bolster must have three Tuberosities, two on the upper, and one on the lower part; and there must be a hollownesse betweene them in the midst, that they may not too straitly presse the sharebone, and so cause paine. The manner of such a Trusse, I found out not long agoe, and it seemed better and safer than the rest for to hinder the falling aowne of the Gut and Kall.

A. Shewes the shoulderband which is tied before and behinde to the girdle of the Trusse.

B. The Trusse.

C. The Cavities left in the midst of the Tuberosities.

When I had seene the oignelle of the *Enterocoele*, I perswaded him to get another

to serve in his place; so having gotten leave of M. Curio Clarke, and Deacon of Divinity, he committed himself unto me: I handled him according unto Art, and commanded him he should never goe without a Trusse; and he followed my directions. When I met him some five or sixe yeares after, I asked him how he did, he answered very well, for he was wholly freed from the disease with which he was formerly troubled; which I could not perswade myself of, before that I had found that hee had told mee the truth, by the diligent observation of his genitals. But some sixe moneths after, he dying of a Pleurisie, I came to Curio's house where hee died, and desired leave to open his body, that I might observe whether nature had done any thing at all in the passage through which the gut fell down. I call God to witnesse, that I found a certaine fatty substance about the proceſſe of the *Peritoneum* about the bignesse of a little egge, and it did sticke so hard to that place, that I could scarce pull it away without the rending of the neighbouring parts. And this was the speedy cause of his cure. But it is most worthy of observation, and admiration, that Nature but a little helped by Art, healeth diseases which are thought incurable. The chiefe of the cure consists in this, that we firmerly stay the gut in its place, after the same manner as these two Figures shew,

We must never
despaire in dis-
eases if so be
nature be
assisted by
Art.

Another Figure of a man having
a Rupture on both sides, shewing
by what meanes, what kinde of
Trusse, and what shoulder-band
he must be bound on each groin.

A. Sheweth the shoulder-band di-
vided in the middest for the put-
ting through of the head.

B. The Trusse, with two bolsters,
betweene which is a hole for put-
ting through the yard. The forme
of both bolsters ought to be the
same with the former.

In the meane time we must not omit diet. We must forbidde the use of all things, which may either relaxe, dilate, or breake the proceſſe of the *Peritoneum*, of which I have already treated sufficiently. Sometimes, but especially in old men, the guts cannot be restored into their place by reason of the quantity of the excrements hardened in them: In this case they must not be too violently forced, but the Patient must be kept in his bed, and lying with his head low, and his knees higher up; let the following Cataplasmes be applied.

Re. rad. alib. & lil ana. ʒij. seminis lini. & sænug. an. ʒß, fol. malvæ, viol. & pariet. an. m. ʒ. Let them be boiled in faire water, afterwards beaten, and drawne through a

to soften the
excrements.

Chymicall
oyle.

scarfe, adding thereto of new Butter without salt, and oyle of Lillies, as much as shall suffice. Make a Cataplasme in the forme of a liquid pultis. Let it be applied hot to the Codde, and bottome of the belly; by the helpe of this remedy when it had beene applied all night, the guts have not seldome beene seene of themselves, without the hand of a Chirurgion, to have returned into their proper place. The windinesse being resolved, which hindered the going backe of the excrements into another gut, whereby they might be evacuated and expelled. But if the excrements will not goe backe thus, the flatulencies, yet resisting and undiscussed, an emollient and carminative Clyster is to be admitted with a little Chymicall oyle of Turpentine, Dill, Iuniper or Fennill. Clysters of Muscadine, oyle of Walnuts and *Aqua vita*, and a small quantitie of any the aforesaid oyles, are good for the same purpose.

It often happens that the guts cannot yet be restored, because the proesse of the *Peritoneum* is not wide enough. For when the excrements are fallen downe with the gut into the codde; they grow hard by little and little, and encrease by the accessse of flatulencies caused by resolution, which cause such a tumor as cannot be put up through that hole, by which a little before it fell downe: whereby it happens that by putrification of the matter there contained, come inflammations, and a new accessse of paine; and lastly, a vomitting and evacuation of the excrements by the mouth being hindered from the other passage of the fundament. They vulgarly call this affe& *Miserere mei*. That you may helpe this symptome, you must rather assay extreame remedies, than suffer the Patient to die by so filthy and loathsome a death. And we must cure it by Chirurgery after this manner following. We will binde the Patient lying on his backe, upon a Table or Bench; then presently make an incision in the upper pard of the codde, not touching the substance of the guts; then we must have a silver Cane or Pipe, of the thicknesse of a Goose quill, round, and gibbous in one part thereof, but somewhat hollowed in the other, as is shewed by this following Figure.

The Figure of the Pipe or Cane:

We must put it into the place of the incision, and put it under the production of the *Peritoneum* being cut together with the codde, all the length of the production; that so with a sharpe knife we may divide the proesse of the *Peritoneum*, according to that cavity separated from the guts there contained, by the benefit of the Cane in a right line not hurting the guts. When you have made an indifferent incision, the guts must gently be put up into the belly with your fingers, and then so much of the cut *Peritoneum* must be sowed up, as shall seeme sufficient, that by that passage made more straight, nothing may fall into the Codde, after it is cicatrized.

But if there be such abundance of excrements hardned, either by the stay or heate of inflammation, that that incision is not sufficient to force the excrements into their place, the incision must be made longer, your Cane being thrust up towards the belly: so that it may be sufficient for the free regresse of the guts into the belly. Then sow it up as is fit, and the way will be shut up against the falling downe of the guts or kall; the proesse of the *Peritoneum* being made more straight, by reason of the future; for the rest, the wound shall be cured according to Art. But before you undertake this worke, consider diligently whether the strength of the Patient be sufficient, neither attempt any thing before you have foretold, and declared the danger to the Patients friends.

CHAP. XVI.

Of the golden Ligature, or the Punctus Aureus, as they call it.

IF the Rupture will not be cured by all these meanes, by reason of the great solution of the continuity of the relaxt, or broken *Peritonaeum*, and the Patient by the consent of his friends there present, is ready to undergoe the danger in hope of recovery; the cure shall be attempted by that which they call the *Punctus Aureus*, or Golden tie.

The Chirurgicall cure by the golden Tie.

For which purpose a Chirurgion which hath a skilfull and sure hand, is to be imployed. He shall make an incision about the share bone, into which he shall thrust a Probe like to the Cane, a little before described; and thrust it long wayes under the proesse of the *Peritonaeum*, and by lifting it up, separate it from the the adjoining fibrous, and nervous bodies, to which it adheres; then presently draw aside the spermaticque vessels, with the *Cremaster*, or hanging muscle of the testicle; which being done, he shall draw aside the proesse it selfe, alone by it selfe: And he shall take as much thereof, as is too lax, with small and gentle mullets, perforated in the midst, and shall with a needle, having five or sixe threds, thrust it through as neere as hee can to the spermaticke vessels, and cremaster muscles. But the needle also must be drawne againe into the midst of the remnant of the proesse, taking up with it the lipps of the wound; then the threed must be tied on a strait knot, and so much thereof must be left after the section, as may be sufficient to hang out of the wound. This threed will of it selfe be dissolved by little and little by putrefaction: neither must it be drawne out before that nature shall regenerate and restore flesh into the place of the ligature, otherwise all our labour shall be spent in vaine.

And lastly, let the wound be clenched, filled with flesh, and cicatrized, whose callous hardnesse may withstand the falling of the gut, or kall.

There are some Chirurgians who would performe this golden Ligature after another manner. They cut the skinne above the share-bone where the falling downe commonly is, even to the proesse of the *Peritonaeum*, and they wrap once or twice about it, being uncovered, a small golden wyre, and onely straiten the passage as much as may suffice, to amend the loosenesse of this proesse, leaving the spermaticque vessels at liberty. Then they twist the ends of the wyre twice or thrice with small mullets, and cut off the remnant thereof; that which remains after the cutting, they turne in, least with the sharpnesse it should prick the flesh growing upon it. Then leaving the golden wyre there, they cure the wound like to other simple wounds, and they keepe the Patient some fiftene or twenty day in his bed, with his knees some thing higher, and his head some thing lower.

Another manner thereof.

Many are healed by this meanes; others have fallen againe into the disease by reason of the ill twisting of the wire.

There is also another manner of this golden tie, which I judge more quicke and safe, even for that there is no externall body left in that part after the cure. Wherefore they wrappe a leaden wyre in steade of the golden, which comes but once about the proesse of the *Peritonaeum*, then they twine it as much as neede requires, that is, not too loosely, least it should leave way for the falling downe of the body, neither too straitly, least a Gangrene should come by hindring the passage of the spirits and nourishment. The ends thereof are suffered to hang out; when in proesse of time, this contraction of the *Peritonaeum* seemes callous, then the wyre is untwisted and gently drawne out. And the rest of the cure performed according to Art. But let not the Chirurgion thrust himselfe upon his worke rashly, without the advice of the Physition, for it diverse times comes to passe, that the testicles are not as yet fallen downe into the Codde by the too great sluggishnesse of nature, in some of a pretty growth, but remains long in the groines, causing a tumor with paine, which thing may make a good Chirurgion believe that it is an *Enterocoele*. Therefore whilst he labours by repelling medicines and trusses to force backe this tumor, he encreaseth the paine, and hinders the falling downe of the testicles into the codde. I observed

The third manner thereof.

A thing to be noted,

A History.

served this not long agoe in a Boy, which an unskillfull Chirurgion had long, and grievously troubled, as if he had had a rupture: for when I had observed that there was but one stone in the Codde, and knew the Boy was never gelt, I bid them cast away the plasters, and trusses, and wisht his Parents that they should suffer him to run and leape, that so the idleing stone might be drawne into the Codde, which thing by little and little, and without paine, had the event, as I foretold. That the reason of this affect may be understood, we must know a man differs from a woman, onely in efficacie of heat; but it is the nature of strong heat to drive forth, as of cold to keepe in. Hence it is that the stones in men hang forth in the codde, but in women they lie hid in the lower belly. Therefore it happens that in some males more cold by nature, the testicles are shut up some certaine time, untill at length they are forc't downe into the codde by youthfull heat. But that we may returne to our former treatise of the codde, although that way of curing ruptures wants not paine and danger, yet it is safer than that which is performed by gelding, which by the cruelty thereof exposes the Patient to manifest danger of death. For the Gelders whilst they feare least when the cure is finished, the relaxation may remaine, pull with violence the proceesse of the *Peritoneum* from the parts to which it adheres, and together with it a nerve of the sixth conjugation which runnes to the stones; they offer the same violence to the spermaticke vessels; by which things ensue great paine, convulsion, efflux of bloud, inflammation, putrefaction, and lastly death, as I have observed in many whom I have dislected, having died a few dayes after their gelding. Although some escape these dangers, yet they are deprived of the faculty of generation for all their life after, for performance whereof nature hath bestowed the testicles, as parts principally necessary for the conservation of mankind. Through which occasion *Galen* hath not feared to preferre them before the heart; because the heart is the beginning of life, but the testicles of a better life; for it is farre more noble to live well, than simply and absolutely to live; therefore Eunuches degenerate into a womanish nature, for they

remain without beards, their voice is weak, their courage failes them, and they turne cowards; and seeing they are unfit for all humane actions, their life cannot but be miserable. Wherefore I will never subscribe to the cutting out of the stones, unless a *Sarcocoele* or Gangrene invade them. But that the way of performing the *Punctus aureus* may be better knowne, I have thought good here to set the instruments, by which this operation is performed, before your view.

Another more easie and safe way to restore the Gut and Kall.

T *Heodoricke* and *Guido* have invented another way of performing this operation. Lib. 3. Cap. 33. They put backe into their places the Gut and Kall being fallen downe, the Patient being so placed, that his thighs are high and his head is somewhat low; then they draw aside the lower portion of the production of the *Peritonaeum*, and also the spermaticke vessels, and cremaster muscle to the *Ischium*; then by applying a causticke fitted to the age and disease, they burne the other part of the proceffe, directly perpendicular to the ihare-bone, where the Gut did fall downe. Then they pull off the eschar thus made with a knife even to the quicke, then they apply another causticke in the same place, which may go even to the bone, then procure the falling of this Eschar made on the foresaid proceffe. And afterwards they heale the ulcer which remaines, which presently contracting somewhat a thicke *Callus*, so keeps up the Guts and Kall, that it bindes them from falling down into the Cod. This way of restoring the Gut and Kall, though it be safer and more facile; yet the Chirurgion must not attempt it, if the Guts or Kall sticke so fast, agglutinated to the proceffe of the *Peritoneum*, that they cannot be severed, nor put backe into their places (for from the guts so burnt and violated, greater mischiefe would ensue) if by the broken and too much dilated proceffe, the bodies thereby restrained, make an exceeding great tumor by their falling downe; if the testicle yet lying in the groine as in a *Bubonocoele*, a kinde of *Enterocoele*, being not yet descended into the *Scrotum* or Codde; if the Patients be not come to such age as they can keepe themselves from stirring, or hold their excrements whiles the operation is performed.

CHAP. XVII.

Of the cure of other kinds of Ruptures.

P *Piplocele* is the falling downe of the Kall into the Groine, or Codde, it hath the same causes as an *Enterocoele*. The signes have beene explained. It is not so dangerous, nor infers a consequence of so many evill symptoms, as the *Enterocoele* doth, yet the cure is the same with the other.

Hydrocele is a waterish tumor in the Codde, which is gathered by little and little betweene the membranes encompassing the testicles, especially the *Dartos* and *Erythroides*; it may be called a particular dropsie, for it proceeds from the same causes, but chiefly from the defect of native heate. The signes are a tumor encreasing slowly without much paine, heavy, and almost of a glassie clearenesse, which you may perceive by holding a candle on the other side, by pressing the Codde above, the water flowes downe, and by pressing it below, it rises upwards, unless peradventure in too great a quantity it fills up the whole capacity of the Codde, yet it can never be forced or put up into the belly as the Kall or Guts may, for oft times it is contained in a Cyste, or bagge; it is distinguished from a *Sarcocoele*, by the smoothnesse and equality thereof. The cure must first be tried with resolving, drying, and discussing medicines, repeated often before, and in the Chapter of the Dropsie; this which followes I have often tried and with good successe.

R. Vng. comitissa. & desiccata. rub. an. ʒij. malaxentur simul; and make a medicine for your case. The water by this kinde of remedy is digested and resolved, or rather dried up, especially if it be not in too great quantity. But if the swelling, by reason of the great quantity of water will not yeeld to those remedies, there is neede of Chirurgery

what a Hydrocele is.

The signes.

The cure.

A medicine to draw forth the contained matter.

rurgery; the Cod and membranes wherein the water is contained, must be thrust through with a Seton, that is, with a large threesquarepointed needle, thred with a skeane of silke; you must thrust your needle presently through the holes of the mullets made for that purpose, not touching the substance of the Testicles. The skean of thred must be left there, or removed twise or thrise a day, that the humor may drop downe, and be evacuated by little and little. But if the paine be more vehement by reason of the Seton, and inflammation come upon it, it must be taken away, and neglecting the proper cure of the disease, we must resist the symptoms.

Some Practitioners use not a Seton, but with a Razor, or incision knife, they open the lower part of the Cod, making an incision some halfe fingers breadth long, penetrating even to the contained water; alwayes leaving untouched the substance of the Testicles and vessels, and they keepe the wound open, untill all the water seemes evacuated; truly by this onely way the cure of a watery rupture whose matter is contained in a Cyste, is safe, and to be expected; as wee have said in our Treatise of Tumors in generall.

What a *Pneumatocoele* is,

The Cure.

The *Pneumatocoele*, is a flatulent tumor in the Codde, generated by the imbecility of heate residing in the part.

It is knowne by the roundnesse, lenity, renitencie and shining. It is cured by prescribing a convenient diet, by the application of medicines which resolve and dissusse flatulencies, as the seeds of Annis, Fennell, Fænugreeke, *Agnus Castus*, Rue, *Origanum*, other things set downe by *Avicen* in his Treatise of Ruptures. I have often used with good successe for this purpose, *Emplastrum Vigonis cum mercurio*; and *Emplastrum Diacalcitheos*, dissolved in some good wine, as Muscadine, with oyle of Bayes.

What a *Sarcocoele* is,

The signes.
Prognosticks,

A *Sarcocoele* is a tumor against nature, which is generated about the stones by a schyrrhus flesh. Grosse and viscide humors breed such kind of flesh, which the part could not overcome and assimilate to it selfe; whence this over-abundance of flesh proceeds, like as Warts doe. *Varices*, or swollen veines often associate this tumor; and it increases with paine. It is knowne by the hardnesse, asperitie, inequality, and roughnesse. It cannot be cured but by amputation or cutting it away; but you must diligently observe, that the flesh be not growne too high, and have already seized upon the Groine, for so nothing can be attempted without the danger of life.

The cure.

But if any may thinke, that he in such a case may somewhat ease the patient by the cutting away of some portion of this same soft flesh, he is deceived. For a *Fungus* will grow, if the least portion thereof be but left, being an evill sure worse than the former; but if the tumor be either small or indifferent, the Chirurgion taking the whole tumor, that is, the testicle, tumefied through the whole substance, with the proceffe encompassing it, and adhering thereto on every side, and make an incision in the Codde, even to the tumor; then separate all the tumid body, that is, the testicle from the Codde: then let him thrust a needle with a strong threed in it, through the middest of the proceffe above the region of the swolne testicle; and then presently let him thrust it the second time through the same part of the proceffe; then shall both the ends of the threed be tied on a knot, the other middle portion of the *Peritoneum* being comprehended in the same knot. This being done, he must cut away the whole proceffe with the testicle comprehended therein. But the ends of the threed, with which the upper part of the proceffe was bound, must be suffered to hang some length out of the wound, or incision of the Codde. Then a repercussive medicine shall be applied to the wound, and the neighbouring parts with a convenient ligature. And the cure must be performed as we have formely mentioned.

What a *Circosocoele* is,

The Cure,

The *Circosocoele* is a tumor of veines dilated, and woven with a various and mutuall implication about the testicle and codde, and swelling with a grosse and melancholy blood. The causes are the same as those of the *Varices*. But the signes are manifest.

To heale this tumor, you must make an incision in the codde, the bredth of two fingers to the *Varix*. Then you must put under the varicous veine, a needle having a double threed in it, as high as you can, that you may binde the rootes thereof: then

let

let the needle be againe put after the same manner about the lower part of the same veine, leaving the space of two fingers betweene the Ligatures. But before you binde the thread of this lowest Ligature, the *Varix* must bee opened in the midst, almost after the same manner as you open a veine in the arme to let blood: That so this grosse blood causing a tumor in the Cod, may be evacuated as is usually done in the Cure of the *varices*. The wound that remains shall be cured by the rules of Art after the manner of other wounds: Leaving the threads in it, which will presently fall away of themselves. To conclude then, it being growne callous especially in the upper part thereof, where the veine was bound, it must be Cicatrized, for so afterwards the blood cannot be strained, or run that way.

Hernia Humoralis is a tumor generated by the confused mixture of many humors in the Cod or betweene the tunicles which involue the testicles, often also in the proper substance of the testicles. It hath like causes, signes and cure as other tumors. While the cure is in hand, rest, trusses, and fit rowlers to sustaine and beare up the testicles are to be used.

Hernia Humoralis.

CHAP. XVIII.

Of the falling downe of the Fundament.

When the muscle called the *Sphincter* which ingirts the Fundament is relaxed, then it comes to passe that it cannot sustaine the right gut. This disease is very frequent to Children by reason of the too much humidity of the belly; which falling downe upon that muscle mollieth and relaxeth it or presseth it downe by an unaccustomed weight, so that the muscles called *Levatores Ani* or the lifters up of the Fundament, are not sufficient to beare up any longer. A great bloody flux gives occasion to this effect. A strong endeavour to expell hard excrements, the *Hæmorrhoides*, which suppressed doe over-loade the right gut, but flowing relaxe it: Cold as in those which goe without breeches in winter, or sit a long time upon a cold stone, a stroake or fall upon the Holy-bone: a palsie of nerves which goe from the Holy-bone to the Muscles the lifters up of the fundament: the weight of the stone being in the bladder.

The causes

That this disease may be healed, we must forbid the Patient too much drincking, too often eating of broth, and from feeding on cold fruits. For locall medicines the part must be fomented with an astringent decoction made of the rinds of Pomegranetts, galls, myrtles, knotgrasse, shepheards purse, Cypressenutts, Alum, and common salt boyled in smiths water or red wine. After the fomentation, the gut be annointed with oyle of Roses or myrtles, and then let it bee gently put by little and little into its place, charging the childe if he can understand your meaning, to hold his breath. When the gut shall be restored, the part must bee diligently wiped least the gut fall downe againe by reason of the slipperinesse of the unction. Then let the powder prescribed for the falling downe of the wombe be put into the fundament as farre as you can: Then you must straitly binde the loynes with a swathe, to the midst whereof behinde let another be fastned which may be tied at the *Pubes* comming along the *Perineum*, so to hold up to the fundament; the better to containe it in its place, a sponge dipt in the astringent decoction. The Patient if he be of sufficient age to have care of himselfe, shall be wished when hee goes to stoole that he sit upon two peeces of wood being set some inch a sunder, least by his straining hee thrust forth the gut together with the excrement; but if he can doe it standing, he shall never by straining thrust forth the gut.

The cure,

But if the gut cannot by the prescribed meanes bee restored to its place, *Hippocrates* bids that the Patient hanging by the heeles be shaken, for so the gut by that shaking will returne to his place: but the same *Hippocrates* wisheth to annoint the fundament, because that remedie having a drying faculty, hath also power

Hippocrates his cure.

to resolve the flatulent humors without any acrimony, by reason of which the gut was the lesse able to be contained in his place.

CHAP. XIX.

Of the Paronychia.

What the Pa-
ronychia is.

He *Paronychia* or *Panaris* is a tumor in the ends of the fingers, with great inflammation, comming of a malignant and venemous humor, which from the bones by the *Periostrum* is communicated to the tendons and nerves of that part which it affecteth, whereof cruell symptoms doe follow, as pulsiſique paine, a feaver, restleſſeneſſe, ſo that the affected through impatiencie of the paine are variously agitated like thoſe tormented with Carbuncles: for which cauſe *Guido* and *Iohannes de Vigo* judge this diſeaſe to be mortall; wherefore you muſt provide a ſkilfull Phyſitian for the cure of this diſeaſe, which may appoint convenient diet, purging and Blood letting. In the meane time the Surgeon, ſhall make way for the virulent and venenate matter, by making incision in the inner part of the finger, even to the bone alongſt the firſt joynt thereof; for *Vigo* ſaith there is not a preſenter remedy, if ſo be that it be quickly done and before the maturation of the matter; for it vindicates the finger from the corruption of the bone and nerves, and aſſwages paine, which I have often and happily tried immediatly at the beginning, before the perfect impreſſion of the virulencie.

Lib. 2. cap. 9.
ora. 8.

But the wound being made you muſt ſuffer it to bleede well, then preſently let him dip his finger in ſtrong and warme vinegar, in which ſome treacle being diſſolved may draw forth the virulencie. But to appeaſe the Paine, the ſame remedies muſt be applyed to the affected part as are uſed in Carbuncles, as the leaves of Sorrell, Henbane, Hemlocke, Mandrake roaſted under the Embers and beaten in a Morter with new *Vnguentum Populeon*, or oyle of Roſes or new butter without ſalt: for ſuch like medicines alſo helpe forward ſuppuration, whileſt by their coldneſſe, they reſſe the extraneous heat affecting the part; and ſo ſtrengthen the native heate being the author of ſuppuration: which reaſon moved the ancient Phyſicians to uſe ſuch medicines in a Carbuncle: but if by reaſon of the fearefulneſſe of the patient, or unſkilfulneſſe of the Surgion, no incision being made, a Gangren and Sphacel ſhall poſſeſſe the part, it remaines that you cut off with your cutting mullets as much of the part as ſhall be corrupt, and perſorme the reſt of the cure according to Art. Yet it doth not ſeldome happen that there may bee no neede to cut off ſuch a finger, becauſe it being corrupted together with the bone doth by little and little diſſolve into a purulent or rather ſanious and much ſtincking filth. But in this affect there is often cauſed an Eſchar by the aduſtion of putredinous heat, and ſuperfluous fleſh indued with moſt exquisite ſence groweth underneath it, which muſt in like manner be cut off with the Mulletts that the part may receive comfort, the paine being aſſwaged by the copious effuſion of blood.

CHAP. XX.

Of the ſwelling of the knees.

Gal. comm.
ad ſent. 1. ſer.
4. lib.
6 Epid. Gal.
Comm. ad ſent.
67. ſect. 2.
pro.

After long and dangerous diſeaſes there oftentimes ariſe Tumors in the knees, and alſo in plethoricke bodies and ſuch as have evill juyce after labours and exerciſe. This kinde of diſeaſe is frequent becauſe the humor eaſily falles into the part which hath beene heated by Labour. But if ſuch

such tumors follow long diseases, they are dangerous and difficult to cure, and therefore not to bee neglected; for bitter paine accompanieth them, because the humor falling thither distends the Membranes, which being many involve the part; besides that this humor participateth of a certaine virulent and maligne quality whether it be cold or hot, when it hath settled into those parts, being such as wee finde in the paines of the joynts, and in the bitings of venomous creatures.

For the cure, if the tumor bee caused by blood, let a slender and refrigerating diet be appointed, and phlebotomy for the revulsion of the antecedent cause; diverse locall medicines shall be used according to the variety of the foure times. But for to allwage the paine, *Anodyne* or mitigating medicines shall be appointed: of all which wee have sufficiently treated in the Chapter of the cure of a Phlegmon.

And because these parts are of exact sence, if there be necessity to open the tumor, yet must we not doe it rashly or unconsiderately, for feare of paine and evill accidents.

This kinde of tumor is oft times raised by winde contained there; in which case the Chirurgeon must bee very provident, that hee bee not deceived with the shew of flowing of the humor, which hee seemes to perceive by the pressure of his fingers, as if there were matter and humor contained therein, and so bee brought to open the tumor. For the winde breaking forth in stead of the humor, causeth evill symptomes by reason of the section rashly made in a part so sensible.

But if watrish humors shall tumifie the part, the body shall first be purged with medicines purging flegme: And then inciding, attenuating, rarifying, discussing and very drying locall medicines shall be used.

Of which wee have abundantly spoken in the Chapter of the *Oedema*. Yet this humor, divers times lyes deepe betweene the whirle bone and the joynt, which causeth it that it cannot be discussed and resolved by reason of the weaknesse of the part and defect of heate, so that the adventitious humor often moves and excludes the bones from their seate. As I have observed it to have happened to many.

In which cause Irrigations of red wine falling something high, whereby the force of the medicine may enter and more easily penetrate, are much commended.

CHAP. XXI.

Of the Dracunculus.

In cannot chuse, but explaine in this place those things which may bee spoken of that kinde of tumor against nature, which by the ancients is called *Dracunculus*. The matter and reason of these hath beene variously handled by diverse Authours, so that hitherto wee have nothing written of them to which wee may by right and with good reason ad-

here as a firme foundation of their essence.

For first for *Galens* opinion, *Lib. 6. de Loc. affect cap. 3.* The generation, saith he, of those hayres which are evacuated by the Urine is worthy no lesse admiration than the *Dracunculi*, which as they say, in a certaine place of *Arabia* breede in the legges of men being of a nervous nature and like wormes in colour and thicknesse.

Therefore seeing I have heard many who have sayd they have seene them, but I my selfe never saw them, I cannot conjecture any thing exactly neither of their originall nor essence.

It is not as yet sufficiently knowne what *Dracunculi* are.

Lib. 4. cap. ult.

Paulus Aegineta writes that the *Dracunculi* are bred in *India* and the higher parts of *Egypt*, like wormes in the musculous parts of mans body, that is, the armes, thighes and legges, and also creepe by the intercostall muscles in children with a manifest motion.

The cure out of *Egineta*.

But whether they be creatures indeede, or onely have the shape of creatures, they must bee cured with a hot fomentation, by which the *Dracunculus* raised to a just tumor, may put forth it selfe, and be pluckt away peece meale with the fingers: also suppurating Cataplasmes may be applyed, composed of water, honey, wheate and barley meale.

Cap 21. lib. 4.
sent. 3. tract. 3.

Avicen being various, having no certainty whereon to rest, inclineth one while to this, and another while to that opinion: for now he speaketh of the *Dracunculi* as of creatures, then presently of a matter and humor shut up in a certaine place; for the rest he rightly delivers the cure and essence of this disease, as we shall afterwards shew.

Lib. 1. cap. ult.

Aetius saith, the *Dracunculi* are like wormes, and that they are found sometimes great, sometimes small, and that their generation is not unlike to that of flat wormes, which are bred in the guttes, for they move under the skinne without any trouble, but in procelle of time, the place becomes suppurate about the end of the *Dracunculus*. The skinne openeth, and the head thereof is thrust forth.

The cure out of *Aetius*.

But if the *Dracunculus* bee pulled, it causeth great greefe; especially if it bee broken by too violent pulling. For that which is left causeth most vehement paine. Wherefore that the creature may not runne backe, the arme must bee bound with a strong threed, and this must bee done every day, that the *Dracunculus* going forward by little and little, may bee intercepted by this binding, but not broken off.

The place must bee bathed with *Aqua Mulsæ* and oyle in which wormewood or southernwood hath beene boyled, or some other of those medicines which are prescribed for the wormes of the belly.

But if the *Dracunculus* going forward of its owne accord, may be easily drawne forth, we must doe nothing else: but if it bee turned to suppuration wee must not leave off the Cataplasmes, the *Aqua Mulsæ* and anointing with oyle: It was usual with him after the taking away of the Cataplasmes, to apply *Emplastrum E Baccis Lauri*: but when it is come to suppuration the skinne must bee opened long wayes, and the *Dracunculus* so layd open must be taken away, but the skinne must be filled with lint, and the rest of the suppurative cure used, so that the creature being suppurated and drawne forth, the wound may bee incarnated and cicatrified.

Tract. 7.
cap. 34.
The cure out of *Rhasis*.

Rhasis writeth, that when the part is lifted up into a blister, and the veine hastneth its egress, it is good for the patient to drinke the first day halfe a dramme of *Aloies*, the next day a whole dramme, the third day two drammes; and in like manner the place affected must bee fomented with *Aloes*, for so that which lyes hid will breake forth: that which shall come forth must be rolled in a pipe of lead, which may equall the weight of a dramme so that it may hang downe, for the veine drawne by the weight will come more forth; and when that which shall come forth is growne much and long, it must be cut off, but not by the roote, but so that a portion thereof may remaine and hang forth, to which the leaden pipe may be fastned, for otherwise it would withdraw it selfe into its skinne and its lurking hole, and so cause a putrid and maligne ulcer.

Therefore wee must gently meete with this disease, and the veine must be drawne by little and little out of the body untill it be all come forth that no worse thing happen: but if by chance it shall happen that as much of the veine as shall bee come forth shall be cut off by the rootes, then the ulcer must be opened long wayes with an incision knife, and that so that whatsoever remains thereof may bee wholly taken away. Then for some dayes the part must be annointed with butter untill whatsoever of such a substance adheres, being consumed with putrifaction shall flow away. Then the ulcer must be cured with sarcoticke things.

There-

Therefore *Rhasis* thus in the same text expresseth the same thing by diverse names, and armed with Iron and Lead, hee comes to the cure thereof, as if hee meant to encounter with some fierce beast.

His opinion
of them.

Soranus the Physician, who lived in the times of *Galen*, was of a quite contrary opinion, as *Paulus Aegineta* in the place being before cited, relates of him; as who denies the *Dracunculus* to be a living creature, but onely a condensation of a certaine small nerve, which seemes both to the Physicians and Patients to have some motion under the skinne.

Soranus his
opinion.

Wherefore *Soranus* seemes to have come neerer the truth than the rest, but yet not so, as throughly to understand, and know the essence of this disease, as we shall demonstrate hereafter.

Manardus writes, that the *Dracunculi* are generated of evill and unlaudable blood, grosse, hot, and melanckolicke, or of adust phlegme very much dried.

Epist. 2. lib. 7.

Gorranus a most learned Physician of our time, *Lib. de Definitionib. medic.* denies any of our Physicians to be able to say any thing of the *Dracunculi*, because it is a disease so unfrequent in these our regions, that it is scarce ever met withall in practice.

The Author of the Introduction, and Medicinall definitions, defines the *Dracunculus* to be a disease very like the *Varices*; then causing great paine, when increasing by little, and little, it begins to bee moved: Therefore to bee cured after the same manner, and by the same method of Section and incision, as the *varices* are. Which thing chiefly seemes to have moved *Guido* to referre this kinde of disease to the *Varices* in his Tractate of Impostumes, because it hath the same cause, and is healed with the same remedy as the *varices*.

But seeing that diverse names have beene imposed upon this disease by severall writers, yet they all have expressed it by the name of a veine: for it is called by *Avicen* and *Guido*, *Vena Medea*, because it is a disease frequent in the Citty *Medina*: by *Albucrafis*, *vena civilis*. *Aliabbas* hath called it *vena famosa*; others have called it *Vena Cruris* or the legge veine. Truly the contrariety of so many opinions repugnant not onely amongst themselves, but also with themselves, easily argueth how little certainty they had of the essence of this disease, who have written of it unto us: To which also this may be added, that none of the latter Physicians have written any things thereof. For although *Jacobus Dalechamphius* a man most conversant in every part of Physicke, hath written much of this matter in his booke of the French Surgery which he set forth some yeares agoe: Yet he hath left us no amplier testimony of his industry, than that hee was very diligent in collecting the writings of the Ancients concerning this thing, interposing no judgement of his owne, the better to assure us of a thing so controverted.

But my modesty cannot so containe me, but that I shall chuse rather to undergoe the censure of being thought too daring, than (as much as in me lyeth,) to suffer this question of the *Dracunculi* to remaine longer ambiguous and undecided. Therefore for the present, I will thus order it, that refuting the opinions of the Ancients I may strengthen by certaine reasons, my opinion of the essence and cure of this disease.

For first, that *Dracunculi* are no living things, nor like unto wormes, nor of like generation as the flat wormes of the belly, which was the opinion of *Aetius*, is easie to disprove both by his writings, as also by reason it selfe. For he writes that the broad worme which hee calls *Tenia*, is as it were a certaine *Metamorphosis* or transmutation of the inner tunicle of the small guttes, into a quicke living and moveable body.

Aetius opinion
confuted.
*Tract. 3. serm.
m. 1. cap. 40.*

But no man ever sayd, neither will he confesse that the *Dracunculi* have the materiall causes of their beginning from the tunicle of the veine, in which they are closed, or from the fibers of a nervous body, to which often they are adjoynd; but much lesse from the skinne under which they lie, may they draw their materiall causes of their originall.

Moreover, neither can there bee any generation of wormes, nor of any other living creatures whatsoever, who have their originall from putrifaction,

unlesse

4. *Meteorolog.*

unlesse by the Corruption of some matter, of whose better and more benigne part, nature by the force of the vitall heat, produceth some animate body, as *Aristotle* teacheth. Wherefore to produce this effect, it is fit the matter should have such a disposition to putrefaction as is required for the generation of such a creature as they would make the *Dracunculus* to be: It is fit the helping causes should concur as assistants to the principalls in the action. And it is meete the place should be opportune or fit.

Naturall Melancholicke humor is most unapt to putrifie.

Stinke an unseparable companion to putrifaction.

But there may be many causes found which may give life to the *Dracunculi*, for by the common consent of all those who have written of them, their generation proceedes from an humor melancholicke, terrestriall and grosse, which by its qualities both by the first coldnesse and driness, as also by the second, that is Aciditie, is not onely thought most unfit of all others for putrefaction, but also is judged to resist putrefaction, as that which is caused by heate and superfluous heate humidity. Besides, if the materiall cause of this disease should be from an humor putrifying and turning by putrefaction into some living creature, it was fit there should be stench also, as being an unseparable accident of putrefaction, for thus the excrements in the guts of which the wormes are generated, doe swell or stinke.

What things usually breed wormes.

Therefore that which exhales from their bodies which are troubled with the *Dracunculi*, should be stinking, as it happeneth to those sicke of the *Pthiriasis* or *Low-sie-evill*. But none of those who have delivered the accidents or symptomes of the *Dracunculi* are found to have made mention hereof. But for the efficient cause whereby so great heat may be rayfed in the places next under the skin, by the efficacy whereof such a creature may be formed of a matter melancholicke and most unapt to putrifie, as they make the *Dracunculus* to be who faine our bodies to be fruitfull monsters; especially seeing the surface of the body is continually ventilated by the small Arteries spread under the skinn, as also by the benefit of insensible transpiration, and breathed with the coolenes of the Aire incompassing us. But now the materiall and efficient causes being defective, or certainly very weake, for the generation of so laborious an effect; what coadjutory cause can yeeld assistance? Can the humidity of meates? for those bodies which are fed with warme and moyst meates, as milke, Cheese, Summer fruits, usually breed wormes, as we are taught by experience in Children.

But on the Contrary, *Avicen* in the place before cited writeth, that meats of a hot and drie temper chiefly breed this kinde of disease, and that it is not so frequent to moyst bodies and such as are accustomed to the Bath, moyst meats and wine moderatly taken. But whether may the condition of the Aire of those regions in which it is as it were, an Endemiall disease, conferre any thing to the generation of such creatures? Certainly for this purpose a cloudy warme and thicke ayre, such as useth to be at the beginning of the Spring when all places resound with frogges, toades and the like creatures bred of putrifaction.

Cap. 83. *Cbir. Gallic.*

But on the Contrary *Iacobus Dalechampius* by the opinion of all the Physicians that have written of the *Dracunculi*, writes that this disease breedeth in the drie and Sun burnt regions of *India* and *Arabia*; but if at the least that part of our body which is next under the skinn should have any opportunity to engender and nourish such creatures, they may be judged to have written that the *Dracunculus* is a living creature with some probability. But if there bee no opportunity for generation in that place, nor capacity for the nourishment of such like creatures as in the guts, if that region of the body be breathed upon with no warmenesse and smothering heat, if it be defiled with none of the grosse excrements, as the gutts usually are, but onely by the subtiller exhalation, which have an easie and insensible transpiration by the pores of the skin, which may seeme to be a just cause of so monstrous and prodigious an effect: but we shall little profit with these engines of reason unlesse we cast downe at once all the Bulwarkes, with which this old opinion of the *Dracunculi* may stand and be defended.

For first they say, why have the ancients expressed this kind of disease by the name of a living thing, that is, of a *Dracunculus* or little Serpent? I answer, because in Physicke names are often imposed upon diseases rather by similitude than from the truth of

of the thing, for the confirmation whereof, the examples of three diseases may suffice, that of the *Cancer*, *Polypus*, and *Elephas*. For these have those names not because any Crabbe, Polypus, or living Elephant may breede in the Body by such like diseases, but because this by its propagation into the adjacent parts represents the feete and clawes of a Crabbe: the other represents the flesh of the Sea-Polypus in its substance; and the third because such as have the Leprosie have their skinnie wrinckled, rough, and horrid with scales and knots, as the skinnie of a living Elephant. So truly this disease of which wee now enquire seemes by good right to have deserved the name *Dracunculus*, because in its whole conformation, colour, quality and production into length and thickeesse it expresseth the image of a Serpent. But whence, will they say (if it be without life) is that manifest motion in the matter? We reply that the humor the cause of this disease is subtrill and hot, and so runnes with violence into the part whence it may seeme to move. But when the *Dracunculi* are separated, why doe they put their heads as it were out of their holes? we answer, in this the ancients have beene very much deceived, because after the suppuration the ulcer being opened, some nervous body being layde bare, thrust forth and subjected it selfe to the sight, which by the convulsive and shaking motion might expresse the crooked creeping of a Serpent. But they will say, paine happens not unlesse to things indued with sence and life, but this *Dracunculus* when he is drawne too violently especially if hee be broken, thereby will cause extreame paine: we doe answer, that the conclusion doth not follow and is of no consequence, for these paines happen not unlesse when the unprovident Surgeon drawes or pulls instead of the *Dracunculus* some nervous or membranous body swolne and replete with an adust humor, whence there cannot but be great paine that part being pulld which is the author of sence. But it is childish to say that the *Dracunculus* feeles, for that it causeth sharpe paines to the living body in which it is. Therefore that at last we may determine something of the nature, essence and generation of these *Dracunculi*, I dare boldly affirme it is nothing else but a tumor and abscesse bred from the heat of the blood in a venenate kinde. Such blood driven by the expulsive facultie through the veines to the Externall parts, especially the limits, that is the Armes and Legges, causeth a tumor round and long often stretched from the joynt of the shoulder even to the wrist, or from the groine even to one of the Anckles with tension, heat, renitency, pricking paine, and a feaver. But this tumor is some whiles stretched forth straight, otherwhiles into oblique and crooked tumors, which hath beene the cause that many taken with this kind of disease, and having their limbes so infolded as with the twinings of a Serpent would say they had a Serpent. I have thus much to say of the *Dracunculi*, especially of those of our owne country.

Why they are called *Dracunculi*.

For the cure, it is not unlike to the cure of a Phlegmon arising from a defluxion, for heere also in like manner the remedies must bee varied according to the foure times of the disease, and the same rule of diet, phlebotomy and purging must be observed which is before prescribed in the cure of a Phlegmon.

The Cure.

The mention of the *Dracunculi* calls to my memorie another kinde of Abscesse, altogether as rare. This our French men name *Cridones*, I thinke a *Crinibus*. i. from hayres: it chiefly troubles children and prickes their backes like thornes. They toss up & downe being not able to take any rest. This disease ariseth from small haire which are scarce of a pins length, but those thicke and strong. It is cured with a fomentation of water more than warme, after which you must presently apply an oyntment made of honey and wheaten flower; for so these haire lying under the skin are allured and drawne forth; and being thus drawne, they must be plucked out with small mullers. I imagine this kinde of disease was not knowne to the ancient Physicians.

So the *Malum pilare* in Aristotle cap. 11. lib. 7. hist. animal.

The End of the Eighth Booke.

OF WOUNDS IN GENERALL.

THE NINTH BOOKE.

CHAP. I.

What a wound is, what the kindes and differences thereof are, and from whence they may be drawne, or derived.

Wound is a solution of Continuity, caused by a stroake, fall, or bite, newly done, bloody, and with putrification, and filth. They also call it a new simple ulcer; for the solution of continuity happens to all parts of the body; but according to the diversity of the parts, it hath divers names amongst the Greekes. For in the flesh it is called *Helcos*, in the bone *Catagma*, in the nerve *Spasma*, in the ligament *Thlasma*, in the vesselles *Apospasma*, in the Muscles *Regma*: and that solution of continuity, which happens in the vessells, their mouths being open, is termed *Anastomasis*, that which happens by erosion, *Anaurosis*; that which is generated by sweating out and transcolation, *Diapedesis*. That these may bee the more easily understood, I have thought good to describe them in the following table.

What a Wound properly is,

Divers appellations of wounds according to the varieties of the parts.

A Table of the differences of Wounds.

| | | | | | | |
|---|---|--|---|---|--|------|
| The differences of wounds are drawne or ta- ken, | From the nature of the parts in which they are made or happen. But these parts are | Either si- milar and these, | Either soft | { | Glandules, | |
| | | | as the | | Flesh, Fat, | |
| | | | Or hard as | | Marrow. | |
| | | | Or of a mid- dle consi- stence, as the | | A Bone, A Gristle: Membranes, Ligaments, Fibers, Vessells, Nerves, Veines, Arteries. | |
| | | Or Orga- nicall and these ei- ther. | Principall | { | Braine, Heart, | |
| | | | as the | | Liver, to which some adde the womb and Testicles. | |
| | | | Or serving the princi- pall, as | | The weason, Lungs, gullet, Stomacke, Guts, Bladder. | |
| | | | Or neither | | The Eares, Nose, Feete, Hands, and other of the same kinde. | |
| | | | | | | from |

| | | |
|---|---------------|---|
| From their proper essence, from whence they are called, | Simple wounds | When there is no complication of any other disease or symptome besides. |
| | Or compound, | When there is a complication of some one or more diseases, which unlesse they be taken away, wee must not hope for to cure the wound. |
| From their quantity according to which they are called, | Great; | Long, Broad, |
| | Indifferent, | Deepe. |
| From their figure, according to which they are named, | Little, | Short, Narrow, |
| | | Superficiarie. |
| | Straight, | |
| | Oblique, | |
| | Cornered. | |

CHAP. II.

Of the causes of Wounds.

Divert denotations from their causes,

ALL things which may outwardly assaile the body with force and violence, may be counted the causes of wounds; which are called Greene, and properly bloody. These things are either animate, or inanimate. The animate, as the bitings, and prickings of beasts. The Inanimate, as the stroake of an arrow, sword, clubb, gunne, stone, a dagger, and all such like things.

From the variety of such like causes, they have divers names: for those which are made by sharpe and pricking things are called punctures: those caused by cutting things, are called wounds or gashes: and those which are made by heavy and obtuse things are named Contusions, or wounds with Contusions.

CHAP. III.

Of the signes of Wounds.

A caution for making resports of Wounds,

Wounds are first knowne by sight, and by the signes drawne from thence. The Chirurgeon ought first and chiefly, to consider, what wounds are curable, and what not; what wounds will scarce admit of cure, and what may be easily cured; for it is not the part of a prudent Chirurgeon, to promise cure in a deadly or dangerous and difficult wound; Least he may seeme to have killed him, whom not the unsufficiencie of the Art, but the greatnesse of the wound hath slaine.

But when the wound is dangerous, but yet without despaire of recovery, it belongs to him to admonish the Patients friends which are by, of the present danger, and doubtfull state of the wound; that if Art shall be overcome by the greatnesse thereof, hee shall not be thought ignorant of the Art, neither to have deceived them.

A Jugling cheating Chirurgeon,

But as this is the part and duty of a good and prudent Chirurgeon, so it is the trick of a cheating and jugling knave, to enlarge small wounds, that so he may seeme to have done a great cure, when it is nothing so.

But it is agreeable to reason, that the Chirurgeon professing the disease easie to be cured, will thinke himselfe in credit bound by such promises and his duty, and therefore seeke all meanes for the quicke recovery of the patient; lest that which was of its owne nature small, may by his negligence become great. Therefore it is expedient, he should know what wounds are to be accounted great.

This

This (as *Galen* saith) is three wayes to be knowne; The first is by the magnitude and principallity of the part affected; for thus the wounds of the Braine, Heart, and of the greater vessels, though small of themselves, yet are thought great. Then from the greatnesse of the solution of continuity; for which cause wounds may be judged great, in which much of the substance of the part is lost in every dimension, though the part be one of these which are accounted servile. Then from the malignitie; through which occasion the wounds of the joynts are accounted great, because for the most part, they are ill conditioned.

Lib. 4. Meth. cap. 6. 1.

Wounds are called great out of three respects.

CHAP. IIII.

Of Prognostickes to be made in Wounds.

W hose Wounds are thought dangerous, wherein any large Nerve, Veine, or Artery are hurt. From the first there is feare of convulsion, but from the other large effusion of the veinous, or arterious blood, whence the powers are debilitated; also these are judged evill, which are upon the arme pitts, groines, leskes, joynts and betweene the fingers; and likewise those which hurt the head or taile of a Muscle. They are least dangerous of all other which wound onely the fleshy substance. But they are deadly which are inflicted upon the Bladder, Braine, Heart, Liver, Lungs, Stomacke and small guts. But if any Bone, Crispe, Nerve or portion of the cheek or prepuce, shall be cut away, they cannot bee restored. Contused wounds are more difficult to cure, than those which are onely from a simple solution of continuity; for before you must thinke to heale them up, you must suppurate and cleanse them; which cannot be done in a short time. Wounds which are round and circular are so much the worse; for there can be no unity unless by an angle, that is, a meeting together of two lines, which can have no place in round wounds, because a circular figure consists of one oblique line. Besides, wounds are by so much thought the greater, by how much their extremes and lipps are the further dis-joynded, which happens to round Wounds. Contrary to these are cornered wounds or such as are made alongst the fibers, as such as may bee easily healed.

What wounds are dangerous.

What least dangerous.
What deadly.
Hip. aphor. 19. Lib. 6.

Why round Wounds are difficult to heale.

Wounds may be more easily healed in young men, than in old; because in them nature is more vigorous, and there is a greater plenty of fruitefull, or good blood, by which the losse of the flesh may be the better and more readily restored, which is slower done in an old body, by reason their blood is smaller in quantity and more dry, and the strength of nature more languide.

Wounds received in the Spring, are not altogether so difficult to heale as those taken in Winter or Summer. For all excesse of heate and cold is hurtfull to them; it is ill for a convulsion to happen upon a Wound, for it is a signe that some Nervous body is hurt; the braine suffering together therewith, as that which is the originall of the Nerves. A Tumor comming upon great Wounds is good; for it shewes the force of nature is able to expell that which is harmefull, and to ease the wounded part. The organick parts wholly cut off cannot againe be united: because a vitall part once severed and plucked from the trunk of the body cannot any more receive influence from the heart as from a roote without which there can bee no life. The loosed continuity of the Nerves, Veines, Arteries, and also the bones, is sometimes restored, not truly, and as they say, according to the first intention, but by the second, that is, by reposition of the like, but not of the same substance. The first intention takes place in the fleshy parts by converting the Alimentary blood into the proper substance of the wounded part. But the second, in the spermatique parts in which the lost substance may be repaired by interposition of some heterogeneous body, which nature, diligent for its owne preservation, substitutes in place of that which is lost: for thus the body, which restores and agglutinats, is no bone but a *Callus*, whose originall matter is from an humor somewhat grosser than that, from whence the bones have their originall and beginning.

Hip. lib. de ul. cer. Hip. aph. 66. lib. 5.

What a *Callus* is and whence it proceeds.

This

Small and
contemptible
Wounds often
prove mortall

Aphor. 1, sect. 1

This humor, when it shall come to the place of the fracture, agglutinateth the ends of the bones together, which otherwise could never bee so knit by reason of their hardnesse. The bones of children are more easily and speedily united by reason of the pliantnesse of their soft and tender substance. Lastly wee must here admonish the Chirurgion, that small Wounds and such as no Artisan will judge deadly, doe divers times kill by reason of a certaine occult and ill disposition of the wounded, and incompassing bodies; for which cause we reade it observed by *Hippocrates*, that it is not sufficient for the Physition to performe his duty, but also externall things must be rightly prepared, and fitted.

CHAP. V.

Of the Cure of Wounds in generall.

The Generall
Indication of
Wounds.

He Chirurgion ought for the right cure of wounds to propose unto himselfe the common and generall indication: that is, the uniting of the divided parts, which indication in such a case is thought upon and knowne even by the vulgar: for that which is dis-joynd desires to bee united, because union is contrary to division. But by what meanes such union may be procured, is onely knowne to the skilfull Artisan. Therefore we attaine unto this chiefe and principall Indication by the benefit of nature as it were the chiefe Agent, and the work of the Chirurgion as the servant of nature. And unlesse nature shall be strong the Chirurgion shall never attaine to his conceived, and wished for end: therefore that he may attaine hereto, he must per forme five things; the first is, that if there bee any strange bodies, as peeces of Wood, Iron, Bones, bruised flesh, congealed blood, or the like, whether they have come from without, or from within the body, and shall be by accident fastened or stucke in the wound, he must take them away, for otherwise there is no union to be expected.

Five things
necessary for
uniting
wounds.

Another is, that he joyne together the lippes of the Wound; for they cannot otherwise be agglutinated and united. The third is, that he keepe close together the joynd lippes. The fourth, that he preserve the temper of the wounded part, for the distemper remaining, it is impossible to restore it to its unity. The fifth is, that he correct the accidents, if any shall happen, because these urging, the Physition is often forced to change the order of the cure.

All strange and externall bodies must bee taken away, as speedily as is possible, because they hinder the action of nature intending unity, especially if they presse or pricke any Nervous body, or Tendon, whence paine or an Abscesse may breede in any principall part, or other serving the principall.

Yet if by the quicke and too hasty taking forth of such like bodies there bee feare of cruell paine or great effusion of bloud, it will bee farre better to commit the whole worke to nature than to exasperate the Wound by too violent hastening.

For nature by little and little will exclude, as contrary to it, or else together with the Pus, what strange body soever shall be containd in the wounded part. But if there shall be danger in delay, it will bee fit the Chirurgion fall to worke quickly, safely, and as mildly as the thing will suffer: for effusion of blood, swooning, convulsion and other horrid symptoms, follow upon the too rough and boystrous handling of Wounds, whereby the patient shall be brought into greater danger than by the wound it selfe.

Therefore he may pull out the strange bodies, either with his fingers, or with instruments, fit for that purpose: but they are sometimes more easily and sometimes more hardly pulled forth, according as the body infixed is either hard or easie to be found or pulled out. Which thing happens according to the variety of the figure of such like bodies; according to the condition of the part it selfe, soft, hard, or deepe, in which these bodies are fastened more straitly or more loosely; and

and then for feare of inferring any worſe harme, as the breaking of ſome Veſſell; but how wee may performe this firſt intention, and alſo the expreſſion of the inſtruments neceſſary for this purpoſe, ſhall be ſhowne in the particular treaties of wounds made by Gun-ſhot, Arrowes and the like.

But the Surgeon ſhall attaine to the ſecond and third ſcope of curing wounds by two and the ſame meanes, that is, by ligatures and ſutures: which notwithstanding before hee uſe, hee muſt well obſerve whether there be any great fluxe of blood preſent, for he ſhall ſtoppe it if it be too violent; but provoake it, if too flow, (unleſſe by chance it ſhall be powred out into any capacity or belly) that ſo the part freed from the ſuperfluous quantity of blood may be leſſe ſubject to inflammation. Therefore the lippes of the wounds ſhall be put together, and ſhall bee kept ſe joyned by ſuture and ligatures: Not truly of all, but onely of thoſe which both by their nature, and magnitude, as alſo by the condition of the parts in which they are, are worthy and capable of both the remedies. For a ſimple and ſmall ſolution of continuity, ſtands onely in neede of the Ligature which we call incarnative, eſpecially, if it be in the Armes or Legges; but that which divides the Muſcles tranſverſly, ſtands in need of both Suture and Ligature; that ſo the Lippes which are ſomewhat farre diſtant from each other, and as it were drawne towards their beginnings, and ends, may bee conjoyned.

Ligatures and Sutures for to conjoyne and hold together the lippes of wounds.

If any portion of a fleſhy ſubſtance by reaſon of ſome great cut ſhall hang downe, it muſt neceſſarily be adjoyned and kept in the place by ſuture. The more notable and large Wounds of all the parts, ſtand in need of Suture, which doe not eaſily admit a Ligature, by reaſon of the figure and ſite of the part in which they are, as the Eares, Noſe, Hairy-ſcalpe, Eie-liddes, Lippes, Belly and Throat.

There are three ſorts of Ligatures, by the joynt conſent of all the Ancients. They commonly call the firſt, a Glutinative or Incarnative; the ſecond Expulſive, the third Retentive. The Glutinative or Incarnative is fit for ſimple, greene, and yet bloody wounds. This conſiſts of two ends, and muſt ſo be drawne, that beginning on the contrary part of the wound, wee may ſo goe upwards, partly croſſing it, and going downewards againe, we may cloſely joyne together the lippes of the Wound. But let the Ligature be neither too ſtrait, leaſt it may cauſe inflammation or paine; nor too looſe, leaſt it be of no uſe, and may not well containe it.

Three ſorts of Ligatures:

What an incarnative Ligature is.

The Expulſive Ligature is fit for ſanious and fiſtulous ulcers, to preſſe out the filth contained in them. This is performed with one Rowler, having one ſimple head; the beginning of binding muſt bee taken from the bottome of the *Sinus*, or boſome thereof; and there it muſt be bound more ſtraightly, and ſo by little and little going higher, you muſt remit ſomething of that rigour, even to the mouth of the Vicer. That ſo (as we have ſaid) the ſanious matter may be preſſed forth.

What an expulſive.

The Retentive Ligature is fit for ſuch parts as cannot ſuffer ſtraight binding, ſuch are the Throat, Belly, as alſo all parts oppreſſed with paine; For the part vexed with paine, abhorreth binding. The uſe thereof, is to hold to locall Medicines. It is performed with a Rowler, which conſiſts ſome whiles of one, ſome whiles of more heads. All theſe Rowlers ought to be of linnen, and ſuch as is neither too new, nor too old; neither too coarſe, nor too fine. Their breadth muſt be proportionable to the parts to which they ſhall bee applyed; the indication of their largeneſſe being taken from their magnitude, figure and ſite. As wee ſhall ſhew more at large in our Tractates of Fractures and Diſlocations.

What the retentive.

What the rowlers muſt be made of.

The Chirurghion ſhall performe the firſt ſcope of curing Wounds, which is of preſerving the temper of the Wounded part, by appointing a good order of Diet by the Preſcript of a Phyſition, by uſing univerſall and locall Medicines. A ſlender, cold, and moyſt Diet muſt be obſerved, untill that time be paſſed, wherein the patient may be ſafe and free from accidents which are uſually feared. Therefore let him bee fed ſparingly, eſpecially if he be plethorick, he ſhall abſtaine from ſalt and ſpiced fleſh, and alſo from wine; If he ſhall be of a Cholerick or Sanguine nature: In ſteed of wine he ſhall uſe the decoction of Barly or Liquerice, or Water and Sugar. He ſhall keepe himſelfe quiet; for reſt is (in *Ceſus* opinion) the very beſt Medicine. Hee ſhall avoyde Venery, Contentions, Brawles, Anger, and other perturbations of the

Why and how the temper of the wounded part muſt be preſerved.

mind. When hee shall seeme to bee past danger, it will bee time to fall by little and little to his accustomed maner of diet and life. Vniverfall remedies are Phlebotomies and purging, which have force to divert and hinder defluxion, whereby the temper of the part might be in danger of change.

In what
wounds blood
letting is not
necessary.

For Phlebotomy it is not alwayes necessary, as in small wounds and bodies, which are neither troubled with ill humours, nor plethoricke: But it is onely required in great wounds, where there is feare of defluxion, paine, *Delirium*, Raving and unquietnesse; and lastly in a body that is Plethoricke, and when the joynts, tendons, or nerves are wounded. Gentle purgations must bee appointed, because the humours are moved and intraged by stronger; whence there is danger of defluxion and inflammation: wherefore nothing is to be attempted in this case, without the advice of a Physitian.

What medici-
nes are to be
judged agglu-
cinative.

The Topick and particular Medicines are Agglutinative, which ought to be inducd with a drying and astringive quality, whereby they may hold together the lips of the wound, and drive away defluxion, having alwayes regard to the nature of the part and the greatnesse of the disease. The Simple Medicines are *Olibanum*, *Aloes*, *Sarcocolla*, *Bole-Armenick*, *Terra sigillata*, *Sanguis Draconis*, Common and Venice Turpentine, Gumme Elemni, Plantane, Horse-tayle, the greater Comfery, *Parina Volatilis*, and many other things of this kind, which wee shall speake of hereafter in our Antidotary.

The fifth scope of healing wounds, is the Correction of those Symptomes or Accidents which are accustomed to follow wounds, which thing verily makes the Chirurgeon have much to doe; For he is often forced to omit the proper cure of the disease, so to resist the accidents and symptomes, as bleeding, paine, inflammation, a feaver, convulsion, palsie, talking idly, or distraction, and the like. Of which wee shall treat briefly and particularly, after we have first spoken of Sutures as much as we shall thinke fitting for this place.

CHAP. VI.

Of Sutures.

What wounds
stand in no
need of a suture

When Wounds are made alongst the thighes, Legs, and armes, they may easily want Sutures, because the solution of continuity is easily restored by Ligatures, but when they are made overthwart, they require a Suture, because the flesh and all such like parts, being cut are drawne towards the sound parts; whereby it comes to passe that they part the further each from other; wherefore that they may be joyned and so kept, they must be sowed, and if the wound be deepe, you must take up much flesh with your needle; for if you onely take hold of the upper part, the wound is onely superficially healed: but the matter shut up, and gathered together in the bottome of the wound, will cause abscesses and hollow Vicers: Wherefore now wee must treat of making of Sutures.

The first man-
ner of suture.

The forme of
your needle.

The forme of
the pipe, with a
window in it;

The first, called *Interpunctus*, leaves the distance of a fingers breadth, and therefore is fit for the Greene wounds of the fleshy parts, which cannot be cured with a Ligature, and in which no heterogencous or strange body remaines; It is performed after this manner. You must have a smooth needle with a threed in it, having a three square point, that so it may the better enter the skin, with the head of it some what hollowed, that the threed may lie therein; for so the needle will the better goe through. You must also have a little pipe with a hole or window in the end, which you must hold and thrust against the lip of the wound, that it bee not moved to the one side or other, whilest you thrust thorough the needle. And that wee may see thorough that window when the needle is thrust thorough, and also draw it together with the threed, and withall hold the lip of the wound in more firmly, that it follow not at the drawing forth of the needle and threed. Having thus pierced the lips of the wound, tie a knot, neere to which cut off the threed; least that if any of it bee left

below

below the knot, it may so stick to the Emplasters that it cannot be plucked and separated from them without paine, when they are taken off. But you must note, the first stitch must be thrust through the midst of the wound, and then the second must be in that space which is betweene the midst and one of the ends; but when you have made your stitches, the lips of the wound must not be too closely joyned, but a little space must be left open betweene them, that the matter may have free passage forth, and the inflammation and paine may be avoyded: otherwise if they shall be closely joyned together without any distance betweene, a tumor after arising when the matter shall come to suppuration, the lips will be so much distended that they may easily be broken by the stitnesse of the threed. But you must neither take hold of too much nor too little flesh with your needle, for too little will not hold, and too much causeth paine and inflammation. And besides leaves an ill favoured scarre. Yet in deepe wounds, such as are those which are made in the thicker Muscles, the needle must be thrust home, that so it may comprehend more of the fleshy substance; least the thred drawne away by the weight of the flesh not taken hold of, may bee broken. But oft times wounds are seene made in such places as it will be needfull, the Chirurgeon should have a crooked needle and pipe, otherwise the Suture will not succcede according to his desire. Wherefore I have thought good to set forth both their figures, that you may use either as occasion shall serve.

*The Figure of Pipes with fenestels in them, and
Needles fit for Sutures.*

The second Suture is made just after the same manner as the Skinners sowe their fells or furs. And the guts must be sowed with this kind of Suture, (if they shall be at any time wounded) that the excrements come not forth by the wound. The 2. manner of Suture,

The third Suture is made by one or more needles having threed in them, thrust through the wound, the threed being wrapped to and againe at the head and the point of the needle, as boyes use to fasten their needle, for feare of losing it, in their caps, or clothes. This kind of Suture is fit in the curing and healing of Hare-lips, as we shall shew you hereafter expressed by a Figure. The third manner of Suture,

The fourth kind of Suture is tearmed *Gastrographia*, invented for the restoring and uniting the great Muscles of the *Epigastrium*, or lower belly, cut with a great wound together with the *Peritoneum* lying under them. The manner whereof we will shew in due place. The 4. kind of Suture termed *Gastrographia*,

The fifth kind is called the Dry Suture, which we use onely in the wounds of the face, which also we will describe in its proper place. The 5. kind called the Dry Suture,

CHAP. VII.

Of the Flux of blood, which usually happens in wounds.

The signes of
blood flowing
from an artery

It times great bleeding followes upon wounds, by reason of some vessell cut, broken, or torne, which there is neede to heale and helped diligently, because the blood is the treasure of nature, without which life cannot consist. The Blood which floweth from an Artery, is thus knowne. It is more subtile, it runs forth as it were leaping, by reason of the vitall spirit contained together with it in the Arteries. On the contrary that which floweth from a Veine is more grosse, blacke, and flow. Now there are many wayes of stanching blood.

The first way
of staying
bleeding.

The first and most usuall is that, by which the lips of the wound are closed, and unlesse it be somewhat deepe, are contained by Medicines which have an astringent, cooling, drying, and glutinous faculty; As *terra sigill. Boli Armeni, ana. ʒ. ʒ. thuris, Mastichis, Myr ha, Aloes, ana. ʒ. ij. Farina velat. molend. ʒ. j. Fiat pulvis qui albumine ovi excipiatur.* Or *R. Thuris & Aloes, ana. partes aequales.* Let them bee mixt with the white of an Egge, and the downe of a hare, and let the pledgets bee dipped in these Medicines, as well those which are put unto the wound as those which are applied about it. Then let the wound be bound up with a double clop and fit Ligature, and the part bee so seated as may seeme the least troublesome and most free from paine.

The 2. manner
of stanching it.

But if the blood cannot be staid by this meanes, when you have taken off all that covereth it, you shall presse the wound and the orifice of the Vessell with your thumbe, so long untill the blood shall bee concrete about it, into so thick a clott as may stop the passage.

The 2. way by
binding of the
vessels.

But if it cannot be thus staid, then the Suture (if any be) must be opened, and the mouth of the Vessell towards the originall or roote, must bee taken hold of, and bound with your needle and threed, with as great a portion of the flesh as the condition of the part will permit. For thus I have staid great bleedings, even in the amputation of members, as I shall shew in fit place. To performe this worke, wee are often forced to divide the skin which covereth the wounded Vessell. For if the Iugular veine, or Artery be cut, it will contract and withdraw it selfe upwards and downwards. Then the skinne it selfe must bee laid open under which it lieth, and thrusting a needle and threed under it, it must be bound as I have often done. But before you loose the knot, it is fit the flesh be growne up, that it may stop the mouth of the Vessell, least it should then bleed.

An admonitiō

The 4. way by
Escharoticks.

But if the condition of the part shall be such as may forbid this comprehension, and binding of the Vessell, we must come to *Escharoticks*, such as are the powder of burnt *Vitriol*, the powder of Mercury, with a small quantity of burnt *Allume*; and *Cawsticks* which cause an *Escar*. The falling away of which must be left to Nature, and not procured by art, least it should fall away before that the orifice of the Vessell shall be stopt with the flesh, or clotted blood.

The 5. way by
cutting off the
vessels.

But some times it happens that the Chirurgion is forced wholly to cut off the vessell it selfe, that thus the ends of the cut vessell withdrawing themselves, and shrincking upwards and downewards, being hidden by the quantity of the adjacent and incompassing parts, the fluxe of blood, which was before not to bee staid, may bee stopped with lesse labour. Yet this is an extreame remedy and not to bee used, unlesse you have in vaine attempted the former.

CHAP. VIII.

Of the paine which happens upon wounds.

He paines which followes upon wounds ought to be quickly aswaged, because nothing so quickly dejects the powers; and it alwayes causes a defluxion, of how good soever a habite and temper the body be of; for Nature ready to yeeld assistance to the wounded part, alwayes sends more humours to it, than are needfull for the nourishment thereof, whereby it comes to passe that the defluxion is easily encreased, either by the quantity, or quality, or by both.

Paines weak-
ken the body,
and causes de-
fluxions.

Therefore to take away this paine the author of defluxion, let such Medicines bee applied to the part as have a repelling and mitigating faculty; as *R. Olei Myrtini, & Rosarum, ana. ʒ. ij. Cera alb. ʒ. j. Farina hordei, ʒ. ʒ. Boli armeni, & terra sigillat. ana. ʒ. vj.* Melt the Waxe in the Oyles, then incorporate all the rest, and according to Art, make a Medicine to be applyed about the part, or *R. Emplast. Diacalcitb. ʒ. iv. Ole. Rosar. & aceti, ana. ʒ. ʒ. liquefiant simul*, and let a Medicine be made for the fore mentioned use. Irrigations of oyle of Roses and Mirtiles, with the white of an Egge, or a whole Egge added thereto, may serve for lenitives, if there be no great inflammation; Rowlers and double cloathes moistened in Oxycrate, will be also convenient for the same purpose. But the force of such Medicines must be often renewed, for when they are dried, they augment the paine. But if the paine yeld not to these, we must come to narcoticke Medicines, such as are the Oyle of Poppy, of Mandrake, a Cataplasme of Henbane and Sorrell, adding thereto Mallowes and Marsh-mallows, of which we spoke formerly in treating of a Phlegmon.

Divers Ano-
dines or medi-
cines to aswage
paine.

Lastly, we must give heed to the cause of the paine, to the kind and nature of the humour that flowes down, and to the way which Nature affects; for according to the variety of these things, the Medicines must be varied, as if heat cause paine, it will be aswaged by application of cooling things; and the like reason observed in the contrary, if Nature intend suppuration, you must helpe forwards its endeavours with suppurating Medicines.

CHAP. IX.

Of Convulsion by reason of a wound.

Convulsion is an unvoluntary contraction of the Muscles (as of parts moveable at our pleasure, towards their originall, that is, the Braine and Spinall Marrow, for by this the Convulsed member or the whole body (if the Convulsion be universall) cannot be moved at our pleasure. Yet motion is not lost in a Convulsion as it is in a Palsie, but it is onely depraved: and because sometimes the Convulsion possesseth the whole body, otherwhiles some part thereof, you must note that there are three kinds of Convulsions in Generall.

Whata Con-
vulsion is.

The first is called by the Greekes, *Tetanos*, when as the whole body growes stiffe like a stake that it cannot be moved any way.

Thres kinds
of an universal
Convulsion.

The second is called *Opisthotonos*, which is when as the whole body is drawn backwards.

The third is termed *Emprostotonos*, which is when the whole body is bended or crooked forwards. A particular Convulsion is, when as the Muscle of the Eye, Tongue, and the like parts which is furnished with a Nerve, is taken with a Convulsion. Repletion or Inanition, Sympathy or consent of paine cause a Convulsion. Abundance of humours cause Repletion, dulling the body by immoderate eating and drinking, and omission of exercise, or any accustomed evacuation, as suppression of

Three causes
of a convulsion
Causes of Re-
pletion.

the Hemorrhoids and Courses: for hence are such like excrementious humours drawne into the Nerves, with which they being replete and filled, are dilated more than is fit, whence necessarily becoming more short, they suffer Convulsion. Examples whereof appeare in Leather and Lute or Viol-strings, which swolne with moysture in a wet season are broken by repletion.

Causes of Inanition,

4pb. 26. sec. 2.

Causes of convulsion by constant of paine.

Signes of a convulsion.

Immoderate vomitings, fluxes, bleedings, cause Inanition or Empriness, wherefore a Convulsion caused by a wound, is deadly: as also by burning feavers. For by these and the like causes, the inbred and primigenious humidity of the Nerves is wasted, so that they are contracted like leather which is shrunk up, by being held too neere the fire, or as fiddle strings which dried with Summers heat, are broken with violence; such a Convulsion is incurable: For it is better a Feaver follow a Convulsion, than a Convulsion a Feaver; as we are taught by Hippocrates, so that such a Feaver bee proportionall to the strength of the convulsifick cause, and the Convulsion proceede from Repletion; for the abundant and grosse humour causing the Convulsion is digested and wasted by the feaverish heat.

The causes of a Convulsion by reason of paine, are either the puncture of a Nerve, whether it be by a thing animall, as by the biting of a venemous beast; or by a thing inanimate, as by the prick of a needle, thorne, or pen-knife: or great and piercing cold, which is hurtfull to the wounds, principally of the nervous parts; whereby it comes to passe, that by causing great and bitter paine in the nerves they are contracted towards their originall, that is, the Braine, as if they would crave succour from their parents in their distressed estate. Besides also, an ill vapour carried to the braine from some putrefaction so vellicateth it, that contracting it selfe, it also contracteth together with it all the Nerves and Muscles, as we see it happeneth in those which have the falling sicknesse. By which it appeares that not onely the braine it selfe suffereth together with the Nerves, but also the Nerves with the Braine. The signes of a Convulsion are difficult, painefull and depraved motions, either of some part or of the whole body, turning aside of the Eyes and whole Face, a Contraction of the Lippes, a drawing in of the Cheekes as if one laughed, and an Univerfall sweat.

CHAP. X.

The cure of a Convulsion.

The cause of a Convulsion by Repletion.

He cure of a Convulsion, is to bee varied according to the variety of the Convulsive cause, for that which proceeds from Repletion must be otherwise cured, than that which is caused by Inanition, and that which proceeds of paine, otherwise than cyther of them. For that which is caused by Repletion is cured by discussing and evacuating Medicines: as by diet conveniently appointed, by purging, bleeding, digestive locall Medicines, exercise, frictions, sulphurous Baths and other things appointed by the prescription of some learned Physicion which shall oversee the cure, which may consume the superfluous and excrementitious humours that possesse the substance of the Nerves, and habit of the body. The locall remedies are Oyles, Vnguent and Liniments, with which the Neck, Back-bone and all the contracted parts shall be annointed. The Oyles are, the Oyle of Foxes, Bayes, Camomill, Wormes, Turpentine, of *Costus*, of *Castoreum*: The Oyntments are *Vnguentum Arragon*, *Agrippa de Althaa*, *Martiatum*. This may be the forme of a Liniment, *R. Olei Chamam. & Laurin. ana. ʒ. ii. Olei Vulp. ʒ. j. Vnguenti de Althaa & Marti. an. ʒ. ʒ. B. Axungia vulpis ʒ. j. Aqua vita ʒ. j. B. Cera quantum sufficit.* Make a Liniment for your use, or *R. Olei Lumbric. de Spica & de Castoreo, ana. ʒ. iiij. Axng. hum. ʒ. j. Sulphuris vivi ʒ. ʒ. B. Cera quantū sufficit.* Make a Liniment, or *R. Vnguenti Martiati, & Agrip. an. ʒ. iiij. Olei de Terebint. ʒ. j. B. Olei Salvia ʒ. ʒ. B. Aqua vita ʒ. j. Cera ʒ. j. B. fiat linimentum.* But this disease is cured by slender diet, and sweating with the Decoctions of *Guaiacum*, because by these remedies the grosse, tough, and viscid excrements, which are in fault, are digested.

A Convulsion proceeding of Inanition is to be cured by the use of those things, which

which doe wholesomly and moderately nourish. And therefore you must prescribe a diet consisting of meats full of good nourishment, as broaths and cullices of Capons, Pigeons, Veale, and Mutton, boyling therein Violet and Mallow leaves. Conserues must be ordained, which may strengthen the debilitated powers, and humect the habit of the body, such as are, the Conserues of Buglosse, Violets, Borage and water Lillies. The following broath will be profitable, *R. Lactuce, Buglos. & portul. ana. M. j. quatuor seminum frigid. major. an. ʒ. ʒ. seminis Barberis, ʒ. j.* Let them all be boiled with a Chicken, and let him take the broath every morning. If thirst oppresse him, the following Iulep will be good. *R. Aquae rosae. ʒ. iv. Aquae viol. lb. ʒ. Saccari albi/semi ʒ. vj. fiat Iulep, utatur in suc.* If the patient be bound in his body, emollient and humecting Clysters shall bee appointed, made of the decoction of a sheeps head and feet, Mallowses, Marsh Mallowses, Pellitory of the wall, Violet leaves, and other things of the like faculty; or that the remedy may be more ready and quickly made: let the Clysters be of Oyle and Milke. Topick remedies shall be Liniments and Bathes. Let this be the example of a Liniment. *R. Olei Viol. & Amygdal. dulc. ana. ʒ. ij. Olei Lillior. & Lumbic. ana. ʒ. j. Axungia porci recentis, ʒ. iiij. Cera nova quantum sufficit, fiat Linimentum,* with which let the whole spine and part affected be annointed: This shall bee the forme of an emollient and humecting Bath. *R. Fol. Malva, Bis Malva, Pariet. ana. M. vj. Seminis Lini & fœnug. ana. lb. ʒ. Coquantur in Aqua communis, addendo Olei Lillior. lb. viij.* Make a Bath: Into which let the patient enter when it is warme. When he shall come forth of the Bath, let him be dried with warme Clothes, or rest in his bed avoyding sweat. But if the patient be able to undergoe the charge, it will be good to ordaine a Bath of Milk, or Oyle alone, or of them equally mixt together.

The cure of a Convulsion caused by inanition.

An Emollient Liniment for any Convulsion.

An Emollient and humecting Bath.

CHAP. XI.

Of the cure of a Convulsion, by sympathy and paine.

Convulsion which is caused both by consent of paine and Communication of the affect, is cured by remedies which are contrary to the dolorifique cause. For thus if it proceede from a puncture or venomous bite, the wound must be dilated and enlarged by cutting the skin, that so the venenate matter may flow forth more freely, for which purpose, also Medicines which are of a thin and liquid consistence, but of a drying and digestive faculty shall be powred in, to call forth & dissolve the virulency, as Treacle & Mithridate, dissolved in *Aqua vite*, with a little of some Mercuriall powder: for this is a noble Antidote. Also cupping glasses and scarrifications will be good. Lastly the condition of all dolorifique causes, shall bee oppugned by the opposition of contrary remedies, as if paine by reason of a pricked Nerve or Tendon, shall cause a Convulsion, it must presently be resisted by proper remedies, as Oyle of Turpentine, of *Euphorbium*, mixt with *Aqua vite*, and also with other remedies appropriated to punctures of the Nerves. If the paine proceede from excesse of cold, because cold is hurtfull to the Braine, the Spinall marrow, and Nerves, the patient shall bee placed in a hot aire, such as that of a Hot-house or Stove, all the Spine of his back and Convulsed parts, must be annoynted with the hot Liniments above mentioned: For that is much better, than suddenly to expose him from the conceaved convulsifike, cause to a most hot fire or warme Bath. In the meane time the Chirurgion must take diligent heede, that as soone as the signes of the Convulsion to come, or already present, or at hand, doe shew themselves, that he put a stick betweene the patients teeth, least they bee fast locked by the pertinacious contraction of the Iawes: for many in such a case have bit off their tongues, for which purpose he shall bee provided of an instrument called *Speculum Oris*, which may be dilated and contracted according to your mind by the meanes of a screw, as the figures underneath demonstrate, the one presenting it open and somewhat twined up, and the other as it is shut.

The cure of a Convulsion by a puncture, or bite.

A worthy Antidote.

You must hinder the locking of the teeth.

The

*The Figure of a Speculum Oris, to open the teeth
when they are locked or held fast together.*

CHAP. XII.

Of the Palsie.

What a Palsie
is.

The differen-
ces thereof.

How it diffe-
rs from a
Convulsion.

The causes.

He Palsie is the resolving or mollification of the Nerves, with privation of sense and motion, not truly of the whole body, but of the one part thereof, as of the right or left side. And such is properly named the Palsie: for otherwise and lesse properly the resolution of some one member is also called the Palsie. For when the whole body is resolved, it is an Apoplexy. Therefore the Palsie sometimes takes halfe the body, otherwhiles the uper parts which are betweene the navell and the head, otherwhiles the lower which are from the navell to the feet; sometimes the tongue, gullet, bladder, yard, eyes, and lastly any of the particles of the body.

It differs from a Convulsion in its whole nature. For in a Convulsion, there is a contention and contraction of the part, but in this a resolving and relaxation thereof: besides, it commonly happeneth that the sense is either abolished or very dull, which usually remaines perfect in a Convulsion. There are some which have a pricking, and as it were great paine in the part.

The causes are internall or externall, the internall are humors obstructing one of the ventricles of the braine, or one side of the spinall marrow, so that the Animall faculty, the worker of sense and motion, cannot by the Nerves come to the part to performe its action. The external causes are a fall, blow, and the like injuries, by which oft times the joynts are dislocated, the spinall marrow wrested aside, and constrictions and compressions of the *Vertebra* arise, which are causes that the Animall spirit cannot come to the Organes in its whole substance. But it is easy by skill in Anatomy perfectly to understand by the resolved part the seat of the morbidique cause, for when there is a Palsie properly so called, that is when the right, or left side is wholly seized upon, then you may know that the obstruction is in the braine, or spinall marrow; but if the parts of the head being untoucht, either of the sides being wholly resolved, the fault remaines in the Originall of the spinall marrow; if the armes bee taken with this disease, we may certainly think that the matter of the disease lies hid in the 5. 6. and 7. *Vertebra* of the neck. But if the lower members languish, we must judge the Paralitick cause to be contained in the *Vertebra* of the loynes and holy bone. Which thing the Chirurgion must diligently observe that he may alwaies have recourse to the originall of the disease. The Palsie which procedes from a Nerve cut,

or

or exceedingly bruised, is incurable, because the way to the part by that meanes is shut against the Animall spirit. Old men scarce or never recover of the palsie, because their native heat is languid, and they are oppressed with abundance of excrementitious humors, neither doth an inveterat palsie which hath long possessed the part, neither that which succeeds an Apoplexy, yeeld us any better hope of cure. It is good for a feaver to come upon a Palsie, for it makes the dissipation of the resolving and relaxing humor, to be hoped for. When the member affected with the palse, is much wasted, and the opposite on the contrary, much encreased in quantity, heat and colour, it is ill: For this is a signe of the extreame weakenesse of the afflicted part, which suffers it selfe to be defrauded of its nourishment, all the provision flowing to the sound or opposite side.

It is good for a feaver to happen upon a Palsie.

CHAP. XIII.

Of the cure of the Palsie.

IN the cure of the Palsie we must not attempt any thing, unlesse we have first used generall remedies, diet and purging; all which care lyeth upon the learned and prudent Physition. The Decoction of *Guaicum* is very fit for this purpose, for it procures sweat and attenuates, digests and drieth up all the humidity which relaxeth the nerves: but when sweat doth not flow, it shall not be unprofitable to put about the resolved members, bricks heated red hot in the fire and quenched in a decoction of Wine, Vineger, and resolving herbs, or also stone bottles, or Oxe and Swines bladders, halfe filled with the same decoction; for such heat which is a Quall resuscitateth & strengtheneth the heat of the part, which in this disease is commonly very languid: Then the Patient shall go into a Bathing-tub, which is vailed or covered over just as we have described in our Treatise of Bathes, that so he may receive the vapour of the following Decoction. *R. Fol. Salvia, Lavend. Lauri major. Absinth. Thym. Angelica, Ruta, ana. M. B. Florum Chamem. Melil. Anethi, Anthos. ana. P. ij. Baccar. Laur. & Juniper. Conquassatar. ana. ʒ. j. Caryophyl. ʒ. ij. Aqua fontana & Vini albi, ana. lb. iv.* Let them be all put in the Vessell mentioned in the Treatise lately described for use. The patient shall keepe himselfe in that Bathing-tub, as long as his strength will give him leave, then let him be put into his bed well covered, where he shall sweat againe, bee dried and rest. Then let him be presently anointed with the following ointment, which *Leonellus Faventinus* much commends, *R. Olei Laurini & de Terebinth. ana. ʒ. iij. Olei Nardini & petrolei, ana. ʒ. j. Vini malvatici, ʒ. iv. Aquæ vitæ, ʒ. ij. Pyrethri, Piperis, Synap. Granor. Junip. Gummi hederæ, anacard. Ladani puri, an. ʒ. j. B. Terantur & misceantur omnia cum Oleis & Vino: bulliant in vasi duplici usque ad Vini consumptionem, facta forti expressione, adde Galbani, Bdellii, Euphorbi, Myrrha, Castorei, adipis ursi, Anatis, Ciconia, an. ʒ. ij.* Make an ointment in forme of a liniment, adding a little wax if need shall require. Or you shall use the following remedy approved by many Physitions, *R. Myrrha & alces. Spicanardi, Sanguinis draconis, thuris, opopanax, Bdellii, Carpobalsami, amomi, sarcocollæ, croci, mastic. gummi arabici, styrac. liquida, ladani, castorei, ana. ʒ. i. Moschi, ʒ. j. aquæ vitæ, ʒ. j. Terebinthina veneta, ad pondus omnium, pulverabuntur pulverisanda & gummi eliquabuntur cum aqua vitæ & aceti tantillo.* And let them all be put in fit vessels, that they may be distilled in *Balneo Maria*, and let the spine of the back, and paralytick limbes be anointed with the liquor which comes from thence. I have often tried the force of this following Medicine. *R. rad. Angel. Treos. floren. gentian. cyperi, ana. ʒ. j. Calami aromatici. Cinam. Caryophyl. nucis Mosch. macis, ana. ʒ. ij. Salvia, major. Iue arthritica, Lavend. rorism. satureia, puleg. calament. mentastri, ana. M. B. florum chamam. melil. hyperic. anthos. sachad. ana. P. j. Concisa omnia contundantur. & in Aqua vit. & Vini malvat. an. lb. ij. infundantur.* And let them be distilled in *Balneo Maria*, like the former, let the affected parts be moistened with the distilled liquor, of which also you may give the patient a spoone full to drinke in the morning with some Sugar. For thus the stomach will be heated, and much phlegme contained therein as the fuell of this disease, will be consumed.

The decoction of *Guaicum* is good for a Palsie.

Things actually hot good for to be applied to paralyticke members.

Leon. Faventinus his ointment.

An approved ointment for the Palsie.

A distilled water good to wash them outwardly, & to drinke inwardly.

Exercises and
frictions.

Chymicall
pyles.

You must also appoint exercises of the affected parts and frequent and hard frictions, with hot linnen clothes, that the native heat may be recalled and the excrements contained in the parts digested: You may also use the Chymicall oyles of Rosemary, Tyme, Lavander, Cloves, Nutmegs, and lastly of all spices, the maner of extracting, whereof we shall hereafter declare in a peculiar Treatise.

CHAP. XIV.

Of Sowning.

What Sown-
ing is,

Three causes
of sowning.

Sowning is a suddaine and pertinacious defect of all the powers, but especially the Vitall; In this the Patients lie without motion and sense, so that the Ancients thought that it differed from death onely in continuance of time. The cause of sowning, which happens to those that are wounded, is bleeding, which causeth a dissipation of the spirits: or feare which causeth a suddaine and joint retirement of the spirits to the heart. Whence followes an intermission of the proper duty as also of the rest of the faculties, whilest they being thus troubled, are at a stand. Also Sowning happens by a putrid and venenate vapour, carried to the heart by the Arteries, and to the Braine by the Nerves; by which you may gather that all sowning happens by three causes. The first is, by dissipation of the spirits and native heat, as in great bleeding. And then by the oppression of these spirits by obstruction, or compression as in a feare, or tumult; For thus the spirits fly back hastily from the surface and habit of the body, unto the heart and center. Lastly, by corruption, as in bodies filled with ill humors, and in poysonous wounds. The signes of Sowning are Palenes, a dewy and sudden sweat arising, the failing of the pulse, a sudden falling of the body upon the ground without sense & motion, a coldnesse possessing the whole body, so that the Patient may seeme rather dead, than alive. For many of these who fall into a sowne dye unlesse they have present helpe.

The cure of
sowning caus-
ed by dissipa-
tion of spirits.

The cure of
sowning caus-
ed by a vene-
nate aire.

The cure of
sowning cau-
sed by oppres-
sion and ob-
struction;

Therefore you shall helpe them, if when they are ready to fall, you sprinkle much cold water in their face, if that the sowning happen by dissipation of the spirits, or if they shall be set with their faces upwards, upon a bed or on the ground, as gently as may be; and if you give them bread dipt in wine to hold and chew in their mouths. But if it be caused by a putrid vapour and poysonous aire, you shall give them a little Mithridat or Treacle in *Aqua vite* with a spoone, as I usually do to those which have the plague, or any part affected with a Gangrene, or sphacell. But if the patients cannot be raised out of their sownes, by reason of the pertinacious oppression and compression of the spirits about the heart, you must give them all such things as have power to diffuse, call forth and resuscitate the spirits, such as are, strong wines to drink, sweet perfumes to smell: You must call them by their owne name, lowd in their care, and you must pluck them somewhat hard by the haire of the Temples, and neck. Also rub the temples, nostrils, wrists and palmes of the Hands with *Aqua vite*, wherein Cloves, Nutmegs, and Ginger have beene steeped.

CHAP. XV.

Of Delirium (i.) Raving, Talking idly or Doting.

What a Symp-
tomaticall
Delirium is.
The causes
thereof.

Why the brain
suffers with
the midriffe.

Doting, or talking idly, here is used for a symptome which commonly happeneth in feavers caused by a wound, and inflammation; and it is a perturbation of the phantasie, and function of the mind, not long induring. Wherefore such a doting happens upon wounds, by reason of vehement paine, and a feaver, when as the nervous parts as the joynts, stomach, and middriffe shall be violated.

For the Ancients did therefore call the Middriffe *Phrene*, because when this is hurt as if the mind it selfe were hurt, a certaine phrensie ensues, that is, a perturbation of the Animall faculty, which is employed in ratiocination; by reason of the community which the *Diaphragma* hath with the Braine, by the nerves, sent from the sixth

Conjuga-

Conjugation, which are carried to the stomach. Therefore doting happens by too much bleeding, which causeth a dissipation of the spirits, whereby it happens that the motions and thoughts of the mind erre, as we see it happens to those who have bled much in the Amputation of a member. And it happens by the puncture of a venomous beast, or from seed retained or corrupted in the wombe, or from a Gangreen or Sphacel, from a venenate and putrid aire carried up to the braine, or from a sudden tumult and teare. Lastly, what things soever with any distemper especially hot, do hurt and debilitate the minde. These may cause doting by the afflux of humors, specially cholerick, by dissipation, oppression or corruption of the spirits. Therefore if it shall

The Cure.

proceede from the inflammation of the braine, and *Meninges* or Membranes therof; after purging and blood letting by the prescription of a Physition, the haire being shaved or cut off, the head shall be fomented with rose vinegar, and then an Emplaster of *Diacalcithea* dissolved in oyle and vinegar of Roses, shall be laid thereupon. Sleep shall be procured with Barley creames, wherein the seeds of white Poppy have been boyled, with broaths made of the Decoction of the cold seedes of Lettuce, Purslane, Sorrell and such like. Cold things shall be applyed to his nostrils, as the seeds of Poppy gently beaten with Rose-water and a little vinegar. Let him have merry and pleasant Companions that may divert his mind from all cogitation of sorrowfull things, and may ease and free him of cares, and with their sweet intreaties may bring him to himselfe againe. But if it happen by default of the spirits, you must seeke remedy from these things which have beene set downe in the Chapter of Sowing.

The End of the Ninth Booke.

OF THE GREENE AND BLOODY VVOVND OF EACH PART.

THE TENTH BOOKE.

CHAP. I.

Of the kinds or differences of a broken Scull.

Now that we have briefly treated of wounds in generall, that is, of their differences, signes, causes, prognosticks and cure, and also shewed the reason of the accidents and symptomes which usually follow and accompany them; it remaines that we treat of them as they are incident to each part, because the cure of wounds must be diversly performed according to the diversity of the parts. Now we will begin with the wounds of the head. Therefore the head hath the hayry scalpe lightly bruised without any wound, otherwhiles it is wounded without a Contusion, and sometimes it is both contused and wounded: but a fracture made in the Scull, is sometimes superficial, sometimes it descends even to the *Diploe*, sometimes it penetrats through the 2. Tables, and the Meninges into the very substance of the Braine; besides, the braine is oft times moved and shaken with breaking of the internall veines, and diverse symptomes happen when there appeares no wound at all in the head: of all, and every of which we will speak in order, and adde their cure, especially according to the opinion of the divine *Hippocrates*. He in his Booke of the wounds of the head, seemes to have made 4. or 5. kinds of fractures of the Scull. The first is called a fissure or fracture, the 2. a contusion or collision, the 3. is termed *Effractura*, the 4. is named *Sedes*, or a seat; the 5. (if you please to adde it) you may call a Counterfissure, or as the interpreter of *Paulus* calls it, a *Resonitus*. As when the bone is cleft on the contrary side, to that which received the stroke. There are many differences of these 5. kinds of a broken Scull. For some fractures are great, some small, and others indifferent; some runne out to a greater length or breadth; others are more contracted; some reside only in the superficies; others descend to the *Diploe*, or else pierce thorough both the Tables of the Scull; some run in a right line, others in an oblique and circular; some are complicated amongst themselves, as a fissure is necessarily and alwayes accompanied with a Collision or Contusion; and others are associated with diverse accidents, as paine, heat, swelling, bleeding and the like. Sometimes the Scull is so broken, that the membrane lying under it, is pressed with shivers of the bone, as with pricking needles. Somewhiles none of the bones falls off. All which differences are diligently to be observed, because they force us to vary the cure, and therefore for the helpe of memory, I have thought good to describe them in the following Table,

The differences of a broke head.

The kinds of a broken Scull out of *Hippocrates*.

Differences from their quantity.

Differences from their figure.

From their complication.

A Table of the fractures of the Scull.

| | | | | | |
|---|---|--|---|---|---|
| <p>A fracture, or solution o, continuity in the Scull is caused either, by</p> | <p>Contusion, that is, a collision of a thing bruising, hard, heavy and obdurate, which shall fall or bee smitten against the head, or against wch the head shall bee knocked, so that the broken bones are divided, or</p> | <p>Keepe their naturall figure and site, touching each other, whence proceeds that fracture of the Scull which is called a fissure, which is</p> | <p>Or obscure and not manifest, when as not the part which received the blow is wounded, but the contrary thereto; and that happens either.</p> | <p>Either manifest, & apparent, that is</p> <p>To your sight, To your feeling, Or instrument.</p> <p>In the same bone, and that 2 manner of waies as</p> <p>In divers bones to wit in such men as want sutures, or have them very close, or disposed otherwayes then is fit, and this opposition is, either</p> | <p>On the side, as for example, when the right side of the bone of the forehead is stricken, the left is cleft.</p> <p>Or from above to below, as when not the first Table which received the blow is cleft, but that which is under it.</p> <p>From the right side to the left, and so on the contrary, as when the right Bregma is struck, and the left cleft.</p> <p>From before to behind and the contrary, as when the forehead is smitten, the noddle is cleft.</p> |
| | | | <p>Or betweene both, that is, the obscure & manifest, as that which is termed a Capillary fissure, and is manifested by smearing it over with oyle, and writing inke.</p> | | |
| | | <p>Or loose that site, and that either</p> | <p>Wholy so that the particles of the broken bone removed from their seat, and falling down, presse the membrane, whence proceeds that kind of effracture which reteines a kind of attrition, when as the bone stricken upon is broken as it were into many fragments shivers and scales, either apparent, or hid in the sound bone, so that it is pressed downe.</p> <p>Or in some sort; as when the broken bone is in some part separated, but in others adheres to the whole bone, whence another kind of effracture arises; you may call it Arched, when as the bone so swells up, that it leaves an empty space below.</p> | | |
| <p>Or by incision of a sharpe, or cutting thing, but that incision is made, either by</p> | | <p>Succission, when the bone is so cut, that in some part it yet adheres to the sound bone.</p> <p>Rescission, when the fragment falls down wholly broken off.</p> <p>Or Seate, when the marke of the weapon remains imprinted in the wound, that the wound is of no more length, nor breadth than the weapon fell upon.</p> | | | <p>Another</p> |

Another Table of the differences of a fractured Skull.

Simple, as when they are found solitary and by themselves.

Their nature, according to which fractures are called,

Compound and that either

Naturally with themselves, as a contusion, or collision with incision, a fissure with an effraction.

Or

with other symptomes, as swelling, paine, heat, bleeding, convulsion and the like.

Their Quantity whence they are called, great, indifferent and small, according to the triple dimension of length, breadth and profunditie.

The differences of fractures common to these of all other parts are drawne, either from

Their figure, from whence they are called.

Right, Oblique, Transverse, Round, Triangular.

Their site, whence they are termed on the fore or backe, or the right or left, or the upper or lower part; or superficially and profound.

The part, whence it is called a Fracture of the Forehead, Nowle, Bregma, and Stony bones; and hence it is judged, what may bee deadly, or hopefull of recovery, easie or difficult to cure.

CHAP. II.

Of the causes and signes of a broken Skull.

He causes of a broken Skull are externall, as a fall, a blow or stroake with any kind of weapon, sharpe, obtruse, heavy, hard, the bitings of Beasts, and many other things of the like kind. But the signes by which we come to know that the Skull is broken, are of two kinds; for some of them are found out by the reasoning and discourse of the mind, other by the sense, as those which lay open the wound to the eye and hand.

The externall causes.

Rationall causes.

Aphor. 50. Sect. 6.

The Rationall signes shew by these things which have happened upon the thing it selfe, whether it be, and of what sort it is. For you may know the Skull is broken, if the patient shall fall down with the stroake, or if he shall fall headlong from a high place upon some hard thing. If for some time after the stroake, he shall lie without speaking, sight, and hearing, if he shall have felt and feele much paine, so that he is often forced to put his hand to the wound. But also the weapon is to be considered, that is, whether it be heavy, obtruse, pricking or sharpe. Also we must consider with what & how great strength the stroake was given, and with how great anger and from what distance the weapon fell. Also he must consider whether the patient received the blow with his head unarmed and naked; whether he fell into a sowne presently after the blow; whether when he came to himselfe, he was in his right senses; whether his eyes were blinded, whether he was troubled with a giddines or dizines, and whether he bled at the nose, mouth, eares, or eyes, and lastly whether he vomited. For Hippocrates writes, that those who have their braine cut, must necessarily have a feaver and vomiting of choler to ensue thereupon, which Galen confirming in his Commentary saith, that the same happens also when the wound comes to the Membranes of the braine.

Also

Lib. 8, cap. 4.

Also a dull sound as from a broken vessell comming from the skull, (the hairy scalpe and *Pericranium* being taken off) and it being lightly smitten upon with an Iron probe, is sayd to be a signe of a fracture thereof, as it is recorded by *Paulus Aegineta*. Truly all these signes make a great conjecture or rather assurednesse that the skull is wounded, and the braine hurt, as which cannot happen unlesse the bone be broken, as *Celsus* hath written. Yet many have had their sculles broken, who had no such signe immediatly after the blow, but this is very seldome. But I doe not thinke fit amongst so many signes, here to omit that which is set downe by *Guido*. If any (saith he) will know in what place the scull is broke, let the patient hold fast betweene his fore teeth, one end of a lute string or thread, and the Chirurgion hold the other in his hand; then let him lightly touch or play upon the string with his fingers; for in the very instant of the sound or stroke, the patient will bee certainly admonished, or perfectly perceive the part of the scull that is broken, and as one come and forst by this sence of paine, will by lifting up his hand make demonstration thereof. As yet I have not beene able to finde the truth hereof by experience, although I have made triall of it in many. Wherefore I cannot say any thing certainly of this signe, as neither of that which is mentioned by *Hippocrates* in *Coac Pras*. In such as you doubt, whether the bones of the scull be broken, or not, you must judge by giving them the stalke of Asphodill, to chaw on both sides of their jawes, but so that you bid them withall observe, whether they perceive any bone to crackle, or make a noyse in their heades, for these which are broken seeme to make a noyse.

Hippocrates
and *Guido*
conjecturall
signes of a
broken scull.

But passing over these things, now let us come to these signes, which may be obvious to our senses.

CHAP. III.

Of the signes of a broken skull, which are manifest to our sense.

Sensible signes
of a broken
scull before
the dividing
of the skinn.

These signes are here sayd to be manifest to sense, which when the bone is bared, manifest the wound to our eyes, fingers and probe. But if the haire stand upon one end in the wound, you may know the bone is broke, because the haire which yeelds to the violence of the blow, cannot be so cut, the bone which resists the stroke being not violated, as it is observed by *Hippocrates*; wherfore we may by the sight of this one thing, before any inspection of the wound it selfe, suspect by a probable conjecture, that the Scull is broken, and perswade the beholders or standers by so much.

Lib. de vulnere
cap.

Moreover we may, before we have cut the skinn acrosse, or baid lare the bone, give a guesse by our feeling, whether the scull be broken, or no, if wee by pressing downe our fingers neere the wound shall perceive the bone either to stand up, or be pressed downe otherwise than it should naturally be.

Whata probe
must be used
in searching
for a fracture.

The skinn being cut crosswise and the bone laid bare, if the fracture be not obvious to the eye, you must trye with your probe, which must neither be too thinn nor too sharpe, least by falling into some naturall cranyes, it may cause us to suspect without any cause that the bone is broken; neither let it be too thick, lest the little clifts may deceive you. If when your probe comes to the bone, it meetes with nothing but that which is smooth and slippery, it is a signe that it is whole.

But on the contrary, if you finde it any thing rough, specially where there is no suture, it shewes the bone is broken. But let the Chirurgion consider, that the fractures are not seldome upon the sutures; and that the sutures have not alwayes one and their naturall site; as also it often comes to passe that the broken cleft, or cut bone can neither be perceived by your sight, nor instrument; wherfore if you thinke there is any such thing, by the rationall signes above mentioned, annointe the place with writing Incke, and oyle, and so you shall find the cracke or clift, by the meanes we shall shew you hereafter.

When you are certaine of the fracture, then you must diligently consider the great-
nesse

ness of the disease, and apply medicines speedily. Verily when a fracture chanceth to light upon any future, the disease is hard to be knowne, unless the fracture be very great, because the sutures by their clifts and roughnesse resemble fractures; wherefore *Hippocrates* saith that he was deceived by them. Now having briefly delivered the differences and signes of a broken scull, it is time to come to the severall kindes thereof, with a Fissure.

Lib. 5. Epid. in Autonomus of Omistam Hippocrates was deceived by the sutures,

CHAP. IIII.

Of a Fissure, being the first kinde of a broken scull.

IF the Chirurgion by the forementioned signes shall know that the scull is broken, or crackt, and if the Wound made in the musculous skin shall not be thought sufficient for ordering the fissure, then must he shave off the haire, and cut with a razour, or incision knife, the musculous skinne with the *Pericranium* lying under it, in a triangular or quadrangular figure to a proportionable bignesse, alwayes shunning, as much as in him lies, the sutures and temples; neither must he feare any harme to ensue hereof; for it is farre better to bare the bone by cutting the skinne, then to suffer the kinde and nature of the fracture to remaine unknowne, by a too religious preservation of the skinne; for the skinne is cured without any great adoe, though pluckt off to no purpose.

Vpon what occasion the hairy scalpe must be cut.

Celsus.

Hippocrates.

For it is much more expedient (in *Hippocrates* opinion) to cure diseases safely and securely though not speedily; than to doe it in a shorter time with feare of relapse and greater inconveniencies. Let this dissection bee made with a razour, or sharpe knife, and if there be any Wound made in the skinne by the weapon, let one of your incisions be made agreeable thereto.

A Razour, or Incision knife.

Now therefore the Musculous skinne together with the *Pericranium* must be divided and cut with a sharpe razour pressed and guided with a strong and stedd hand; then must it be so pluckt from the bone, or scull lying under it, that none thereof remaine upon the bone; for if it should be rent or torne with the Trepane, it would cause vehement feavers with inflammation. You must beginne to pull it backe at the corners of the lines crossing each other with right angles, with this Chissell whose figure you see here expressed.

The manner how to pull the hairie scalp from the broken scull.

A Chissell or Instrument to pull backe or separate the Pericranium from the Scull.

Then you must fill all the wound with boulders of fine soft linte, that so the lippes may be kept further a sunder. But you shall apply upon it medicines fit to stanch blood. But if it come so to passe that the blood flowes forth so violently, that it can be stayed by no meanes, the vessell it selfe must be bound, after this manner

First thrust thorough the musculous skinne on the outside with a needle and thred, then thrust the needle backe againe; then tye the thred on a knot on the outside, but first put some lint rolled up to the bignesse of a Goose quill betweene the thred and the hairy scalpe on both sides thereof, least the strait twitching of the

The manner to binde a vessel in case of too much bleeding.

thred which may serve to stay the bleeding, may cut and teare the skinne, or cause paine: then must you raise his head somewhat higher.

A History.

I have lately tried, and performed this upon a certaine Coach-man, who throwne from the Coach upon his head on a pavement of freestone, exceedingly bruised the hind part of the *Bregma*, for which cause it was fit to open the Musculous skinne, with a crosse incision, both that the congealed blood might bee pressed out, as also that the fracture (if there were any) might be observed. But an Artery being cut in performance hereof, when as the Chirurgion who was there present could not stay the blood leaping out with violence; and the Coachman already had lost so great a quantity thereof, that his strength was so much decayed, that hee could not stirre himselfe in his bed, or scarce speake: I being called, shewed them by experience, that whereas astringent medicines were used before to no purpose, it was better to stay the bleeding by binding the vessell, than to let the patient die for a childish feare of pricking him.

after the tenth
day.**

But that we may returne to our former matter, the Chirurgion shall the next day consider with what kinde of fracture the bone is hurt; and if no signes of hurt appeare to the eyes, nor be perceived with your fingers and probe, yet some of the rationall signes may cause one to have a conjecture that there is a fracture: Then you must annoint as we told you before, the bared bone with writing Inke, and a little oyle of Roses; that the cleft or cracke may be dyed or coloured therewith, if that there be any there. Then the next dressing you must drie the bone with a linnen cloth, and scrape off the Inke, and oyle, with scraping Instruments made for the purpose: if any part thereof, shall be suncke into the bone; for if there be any cracke, it will bee black; Wherefore you must continue scraping untill no signe of the fissure remaine, or else untill you come even to the *Dura Mater*. But that he may be more certaine whether the fissure pierce thorough both the Tables of the scull, he must bid the Patient, that stopping his nose & mouth, he strive to breathe with a great endeavour. For then bloody matter or *sanies* will sweat thorough the fissure: For the breath driven forth of the chest, and prohibited passage forth, swells and lifts up the substance of the braine, and the *Meninges*, whereupon that frothy humidity and *Sanies* sweats forth. Therefore then the bone must be cut even to the *Dura Mater*, with *Radula* and other scraping Instruments, fit for that purpose, yet so as you hurt not the membrane; but if the fissure shall be somewhat long, it will not bee convenient to follow it all the extent thereof: for nature will repaire and restore the remnant of the fissure by generating a *Callus*; besides also the Chirurgion according to *Celsus* opinion must take away as little of the bone as he can, because there is nothing so fit to cover the braine, as the scull. Therefore it shall suffice to make a passage, whereby the blood and *Sanies* may passe and be drawne forth, least that matter being suppressed may corrupt the bone, and cause an inflammation in the braine. But the broken bone must bee taken forth within three dayes if it be possible, especially in Sommer for feare of inflammation. Yet I have oftentimes taken forth with a Trepan and with Scrapers the bones of the scull, after the seaventeenth day, both in Winter & Sommer; and that with happy successe. Which I have the rather noted, least any should, at any time, suffer the wounded to be left destitute of remedie: for it is better to trie a doubtfull remedie than none: Yet the By-standers shall be admonished and told of the danger, for many more die who have not the broken bones of the scull taken out, than those that have.

But the Instruments, with which the wounded or cleft bones may be cut out are called *Scalpri* or *Radula*, of which I have caused diverse sorts to be here decyphered, that every one might take his choice, according to his minde, and as shall bee best for his purpose. But all of them may be scrued into one handle, the figure whereof I have here exhibited.

Radula

Radulæ or Scalpri (i) Shavers or Scrapers.

Radulæ of another forme, for the better cutting of the greater bones.

To conclude, when the skull shall be wounded or broken with a simple fissure, the Chirurgion must thinke he hath done sufficient to the patient; and in his *Art*, if hee shall divide the bone and dilate the fissure or cleft with the described Instruments, though he have used no Trepan, although the fissure pierce thorough both the Tables. But if it doth not exceed the first Table, you must stay your scrapers as soone as you come to the second, according to the opinion of *Paulus*: but if the bone shall be broken, and shivered into many peeces, they shall be taken forth with fit Instruments, using also a Trepan if neede shall require, after the same manner as we shall shew you hereafter.

It is sufficient in a simple fissure to dilate it with your Scalpri onely and not to Trepan it.

CHAP. V.

Of a Contusion, which is the second sort of fracture.

IN *Ecchymosis*, that is, an effusion of blood, presently concreting under the musculous skinne, without any wound, is oft caused by a violent Contusion. This Contusion if it shall be great, so that the skinne be devided from the skull, it is expedient, that you make an incision, whereby the blood may bee evacuated and emptied. For in this case you must wholly desist from suppurative medicines, (which otherwise would be of good use in a fleshy part) by reason that all movst things are hurtfull to the bones, as shall be showne hereafter.

Such like Contusions more frequently happen in children, being easily perceived by the softnesse, and inundation of the contused part: forth of which oft times when I have opened them with my incision knife, serous, clotted and blackish blood hath issued

What an *Ecchymosis* is.

How a contusion of the skull must be cured.

Different
cures of a de-
pressed skull,

issued. The residue of the cure is perfected by moderate compression of the part, and drying medicines. Moreover the scull of a child, may bee pressed downe, by a great contusion, even as wee see it happens in thin vessels of brasle, lead, or pewter, for oft times by the pressure of your finger, they are so dented in, that the print thereof remaines; yet sometimes they fly backe of themselves, and againe acquire their former plainesse and equabilitie, which also happens, in the bones of children, women, and such as are soft, humide and phlegmaticke. But if the bones doe not spring backe of themselves, you must apply a cupping glasse with a great flame; with-
all commaund the patient, to force his breath up as powerfully as he can, keeping his mouth and nose close shut; for thus there will be hope, to restore the depressed bone to its place, by the spirits forst upwards to the braine and scull, by the powerfull attraction of the cupping glasse. But if so bee that the bone cannot by this meanes be restored, then you must make an incision in the skinne, and fasten such a Trepan,

as you see heere deliniated, into the deprest, or settled part of the bone, and so pull it directly upwards, just as wee see Coopers raise the staves of their caske, when they are sunke too much in,

But if the bone shall be too strong, thicke, and dense, so that this Instrument will not serve to plucke it forrh; then you must perforate the scull, in the very center of the depression; and with this threefold Instrument, or Levatory put into the hole, lift up and restore the bone to its naturall site; for this same Instrument is of strength sufficient for that purpose. It is made with three feete, that so it may be applyed to any part of the head which is round; but divers heads may be fitted to the end thereof according as the businesse shall require, as the figure here placed doth shew.

A three footed Levatorie.

A deliniation of other Levatories.

A. Shewes the point or tongue of the Levatory, which must be somewhat dull, that so it may bee the more gently and easily put betwene the Dura Mater and the scull, and this part thereof may be lifted up so much by the head or handle taken in your hand, as the necessity of the present operation shall require.

B. Intimates the body of the Levatory, which must bee foure square, lest the point or tongue put thereon should not stand fast, but the end of this Body must rest upon the sound bone, as on a sure foundation.

The use thereof is, thus: put the point or tongue under the broken or depressed bone, then lift the handle up with your hand, that so the depressed bone may bee elevated.

C. Shewes the first Arme of the other Levatory, whose crooked end must bee gently put under the depressed bone.

D. Shewes the other Arme, which must rest on the sound bone, that by the firme standing thereof, it may lift up the depressed bone.

But if at any time it comes to passe, that the bone is not totally broken or deprest, but onely on one side; it will be fit, so to lift it up, as also to make a vent for the issuing out of the filth, to devide the scull with little sawes like these, which ye see here expressed, for thus so much of the bone, as shall be thought needefull, may be cut off without compression, neither will there be any danger of hurting the braine or membrane with the broken bone.

The Figures of Sawes fit to divide the scull.

But if by such signes as are present, and shall appeare, wee perceive or judge that the contusion goes but to the second Table, or scarce so farre, the baring or taking away of the bone, must go no further than the contusion reaches, for that will bee sufficient to eschew and divert Inflammation and divers other symptomes. And this

this shall be done with a scaling or Desquamatory Trepan (as they terme it) with which, you may easily take up as much of the bone, as you shall thinke expedient. And I have here given you the figure thereof.

A Desquamatorie or Scaling Trepan.

CHAP. VI.

Of an Effracture, depression of the bone, being the third kinde of Fracture.

Efore I come to speake of an Effracture, I thinke it not amisse to crave pardon of the courteous and understanding Reader, for this reason especially, that as in the former Chapter, when I had determined and appointed to speake of a Contusion, I inserted many things of a Depression; so also in this chapter of an Effracture, I intend to intermixe something of a Contusion; wee doe not this through any ignorance of the thing it selfe; for wee know that it is called a contusion, when the bone is deprest and crusht, but falles not downe. But an Effracture is when the bone falls downe and is broken by a most violent blow. But it can scarce come so to passe, but that the things themselves must be confounded and mixt, both as they are done; and also when they are spoken of: so that you shall scarce see a Contusion without an Effracture, or this without that. Therefore the bones are often broken off and driven downe with great and forcible blowes, with clubbes whether round or square, or by falling from a high place directly downe, more or lesse according to the force of the blow, kinde of weapon, and condition of the part receiving the same: Wherefore you must bee provided with diversity of remedies and Instruments to encounter therewith. Wherefore admit the bone is pressed downe, and shivered into many peeces, now for that these splinters neede not be taken out with a Trepan: you may do the businesse with Levatories made and neatly fashioned for that purpose; such as these, which are here expressed.

What a contusion is.

What an Effracture is.

The causes of Effractures.

The cure.

A Levatorie.

But we must have speciall care, least that in pulling and taking out of these scales and splinters, we hurt the membranes. These scales are sometimes very rough & prickly, so that they cannot touch the *Meninges* without offence; but somewhiles the businesse is so intricate, that they cannot be taken out unlesse by enlarging the fracture. Wherefore in this case, if there be a space so large, as that the ends of these mullets may enter, you may easily sheare off so much of the bone, as shall be necessary and requisite for the taking away of these scales, without any assistance of the Trepan, which I have done very often and with good successe; for the operation performed by these mullets is far more speedy and safe, than that with the Trepan; and in the performance of every operation, the chiefe commendation is given to safenesse and celeritie.

Cutting

Cutting Mullets, commonly called, Rostra Psittaci, or Parrots-beakes.

Moreover I have thought good here to give you the figures of chissells, scrapers, and Pincers, together with a leaden mallet, because such Instruments are not onely very necessary to take forth the scales of bones which are broken, but also to plaine, and smooth those which remaine whole.

The Figures of Scrapers, Pincers, a Leaden Mallet, &c.

But here you must note, that a Trepan nor Levatorie must never bee applyed to a bone quite broken, lest the membranes lying under it bee hurt by the compression thereof. Therefore you must apply them to a sound bone, but as neare as you can to the fracture, so that you take away as little of the scull as is possible, lest the braine despoiled of its bonie cover, take some harme thereby. Neither Effractions, nor yet fissures if they bee of some length, must be followed to their ends, but thinke your selfe well, if you have made a passage for the issuing forth of the Sanies or filth, and have drawne forth that bone, which pricked the membranes. For nature is accustomed by generating a *Callus* to soulder, or unite the bones of the scull, as it also doth these of the other parts, as wee have

read it written by *Hippocrates* and *Galen*; for which purpose it hath by singular providence replenished both the Tables of the scull, with a certaine alimentarie and bloody matter, that with this, as with marrow it might repaire the losse and defect of the bone.

The truth hereof was lately manifested in the servant of Master *Grolo*, who had an Effraction on the coronall bone, by a greevous blow, given him with the foote of a Mule; which when I understood, I devided the musculous skinne with a three cornered section in that place, with an intent to apply a Trepan there; wherefore the day following, the bone being bored, and when I thought to draw it forth, yea verily endeavoured to plucke it forth, being already divided with the Trepan; I perceived a fearefull production of an Effraction; by the moveablenesse of the bone shaking under my hand; for it reached from the midst of the forehead, to the lesser corner of the eye.

*Hip. lib. de
Vuln. cap.
Gal. lib. 6.
meth. cap. ult.*

A History.

eye. Wherefore omitting both my determination and endeavour to pull it forth, I thought I should doe sufficiently for the patient : if I should only raise up the bone which was deprest; for so it did not trouble the *Crassameninx* by pressing it, and the matter, and filth, were let forth by a passage made with a saw. So that in conclusion, he recovered perfectly, but that he lost one of his eyes which was adjoyning to the fracture.

CHAP. VII.

Of a Seate, being the fourth kinde of a broken Scull.

What a seate
is.

Hippocrates calls a seate that kinde of Fracture of the scull, when the weapon to falls upon the scull, that the fracture reteining the print thereof, is neither stretched forth any further, nor contracted to any lesse space.

The cure.

And seeing there be many formes hereof, they all whether they shall bee superficially, or shall pierce even to the *Diploe*, or else passe through both the Tables, whether it be with any losse of the bonic substance, whether it runne long wayes, or else be but short, or otherwise are dilated to some breadth, or else bee but narrow; whether they shall be done with a cut, or with a pricke with a dagger, stelletto, lance or other kind of weapon, whether they shall have this or that accident joyned with them, I say all of them, how many and various soever they be, ought and must be cured by some of the formerly described Instruments and meanes. Yet this must be noted, which as yet wee have not remembred, that if it happen by a violent stroake, and great wound, that a portion of the bone is wholly so cut off, that it is cleane severed from the rest of the scull, and hang only by the *Pericranium* and musculous skinne; yet you must not plucke it from the *Pericranium*, and cast it away as unprofitable, but restore it to its proper seate and place, so by the force of nature, to be glewed by a *Callus*, as *Celsus* hath observed.

Lib. 8. cap. 4.

A History,

I have tryed the truth of this experiment, in captaine *Hydron* not very long agoe. He had the middle part of the *Os Coronale*, of the bredth, and length of three fingers, so cut with a sharpe sword, that it stucke not to the rest of the bone; but scarce adhearing to the *Pericranium* and musculous skinne; but lay turned downe over his face, so that the *Dura Mater* was plainely seene; wherefore I prepared to plucke it from the skinne, and cast it away, but that I remembred *Hippocrates* precept, where hee bids, that the Braine should not be robbed of its cover and left bare. Wherefore first of all I wiped away the blood which was fallen upon the *Dura Mater*, whose motion you might plainely see, then I restored the portion of the bone, to its place, and fastned it on the upper side with a suture consisting of three stiches; and that the residue of the matter might have passage forth, I filled the places betweene each stitch with linte; by this meanes, he by the mercy of God, recovered, though at the same time he received many other large wounds in his bodie; which is a certaine experiment, that we must cast away no part of the scull, nor of the *Pericranium*, no not of the musculous skinne, unlesse necessity urge; therefore much lesse to leave the braine naked and despoiled of its coverings.

CHAP. VIII.

Of a Resonitus, or Counter-fissure, being the fifth kinde of Fracture.

What a Resonitus
is.

Sometimes the fracture is made in the part opposite to that which received the blow; as if the right side be stricke, the left is cloven; this kinde of fracture is very dangerous, because wee cannot finde it out by any certaine signe, as it is written by *Hippocrates Lib. de vuln. Capitis*. Wherefore if at any time the patient dye of such a fracture, the Chirurgion must be pardoned.

And

And although *Paulus Aegineta* laugh at this kinde of fracture and thinkes that it cannot happen to a mans head, as that which is hard and full, as it happens in empty glasse bottles, yet I have sometimes seene and observed it.

Lib. 6. cap. 90.

Neither is their reason of any validity, who thinke nature therefore to have framed the head of many bones knit together by sutures, lest the fracture of the one side, should be stretched to the other. For peradventure this may take place, in such as have expresse sutures, seated and framed according to nature. But it takes no place in such as either want them, or have them not seated according to nature, or have them very close and so defaced that it may seeme one bone growne together of many; This shall be made manifest by recitall of the following Historie.

In whom this fracture may take place in diverse bones of the scull.

A servant of *Massius* the Poste-master had a greevous blow with a stone, upon the right *Bregma*, which made but a small wound, yet a great contusion and Tumor: Wherefore that it might more plainly appeare, whether the bone had received any harme, and also that the congealed blood might be pressed forth, the wound was dilated, the skinne being opened by *Theodore Herens* the Chirurgion, who as hee was a skillfull workeman and an honest man, omitted nothing which Art might doe for his cure. When he had divided the skinne, the bone was found whole, although it was much to bee feared, that it was broken, because he fell presently to the ground with the blow, vomited and shewed other signes of a fractured scull; so it happened that he dyed on the one & twentieth day of his sicknes. But I being called to learne, & search how he came by his death, deviding the scull with a saw, found in the part opposite to the blow, a great quantity of *Sanies* or bloody matter, and an Abscesse in the *Crasa meninx*, and also in the substance of the very braine, but no sutures, but the two scaly ones. Therefore that is certaine which is now confirmed by the authority of *Hippocrates*; as also by reason and experience, that a blow may bee received on the one side, and the bone may be fractured on the opposite, especially in such as have either no sutures, or else so firmly united and closed, that they are scarce apparent.

A History.

Neither is it absurde, that the part, opposite to that which received the stroake, of the same bone and not of diverse bones may be cloven, and in those men who have their sculls well made, and naturally distinguished and composed with sutures; and this both was and is, the true meaning of *Hippocrates*. That this may bee the better understood, we must note that the opposite part of the same bone may be understood two manner of wayes. First, when the fracture is in the same surface of the smitten bone, as if that part of one of the bones of the *Bregma* which is next to the Lambdall future be smitten, and the other part next to the Coronall future be cloven. Secondly, when as not the same superficies and table which receives the blow, but that which lyes under it is cleft, which kind of fracture I observed, in a certaine Gentleman a Horseman of Captaine *Stempans* troope; He in defending the breach of the wall of the Castle of *Hisdin* was stricke with a Musket bullet upon the *Bregma*, but had his helmet on his head; the bullet dented in the Helmet but did not breake it, no nor the muscular skinne, nor scull, for as much as could be discerned, yet notwithstanding hee died apoplecticke upon the sixth day after.

The Resonitua may be in the same bone of the scull.

A History.

But I being very desirous to know, what might be the true cause of his death, dividing his scull, observed that the second table was broken, and cast off scales and splinters, wherewith as with needles the substance of the braine was continually pricked, the first and upper table being whole, for all this: I afterwards shewed the like example to *Capellanus* and *Castellanus* the King and *Queenes* chiefe Physicians in the expedition of *Roane*.

But *Hippocrates* prescribes no method of curing this fifth kind of fracture, by reason he thinks it cannot be found out by any circumstance, whence it happens that it is for the most part deadly. Yet must we endeavour to have some knowledg & conjecture of such a fracture, if it shall at any time happen. Wherefore having first diligently shaved away the haire, we must apply an Emplaster of Pitch, Tarre, Waxe, Turpentine, the powder of *Iris*, or floure deluce rootes, and mastich; now if any place of the head shall appeare more moyst, soft and swollne, it is somewhat likely that the bone is cleft in that place, so that the patient, though thinking of no such thing, is now & then

Why Hippocrates set downe no way to cure a Resonitus.

The manner to know when the scull is fractured by a Resonitus.

forset to put his hand to that part of the scull. Confirmed with these and other signes formerly mentioned, let him call a counsell of learned Physitions; and foretell the danger to the Patients friends which are there present, that there may no occasion of calummie remaine, then let him boldly perforate the scull; for that is far better, than forsake the patient ready to yeelde to the greatnesse of the hidden disease, and so consequently to dye within a short while after. There are foure sorts, or conditions of fractures, by which the Chirurgion may be so deceived, that when the scull is broken indeed, yet he may thinke there is no fracture. The first is when the bone is so depressed, that it presently rises up into its true place, and native equability. The second is when the fissure is onely capillary. The third is when the bone is shaken on the inside, the utter surface neverthelesse remaining whole, forasmuch as can be discerned. The fourth is, when the bone is stricken on the one side and cleft on the other.

CHAP. IX.

Of the moving, or Concussion, of the Braine.

*Gal. lib. 2. de
comp. medic.
cap. 6. & Com.
ad Aph. 8. §
sect. 7.*

Besides the mentioned kindes of fractures by which the braine also suffers; there is another kinde of affect besides nature, which also assailes it by the violent incursion of a cause, in like manner, externall; they call it the Commotion or shaking of the braine, whence Symptoms like those of a broken scull ensue. Falling from aloft upon a solide and hard body, dull and heave blowes, as with stones, clubbes, staves, the report of a peece of Ordinance, or cracke of Thunder, and also a blow with ones hand.

Lib. 5. Epidem.

Thus as *Hippocrates* tells, that beautifull damosell the daughter of *Nerius*, when she was twenty yeeres old, was smitten by a woman, a friend of hers, playing with her, with her flat hand upon the fore part of the head, and then she was taken with a giddines, and lay without breathing, & when she came home, she fell presently into a great Feaver, her head aked, and her face grew red. The seaventh day after there came forth some two or three Ounces of stincking and bloody matter about her right eare, and shee seemed somewhat better and to be at somewhat more ease. The feaver encreased againe, and she fell into a heaveie sleepinesse, and lost her speech, and the right side of her face, was drawne up, and she breathed with difficulty, she had also a convulsion and trembling; both her tongue failed her, and her eyes grew dull, on the ninth day she dyed. But you must note, that though the head be armed with a helmet, yet by the violence of a blow, the Veines, and Arteries may be broken, not onely these which passe through the futures, but also these which are disperfed betweene the two tables in the Diploe, both that they might binde the *Crasa Meninx* to the scull, that so the braine might move more freely, as also that they might carry the alimentary juice to the braine wanting marrow, that is, blood to nourish it, as we have formerly shewed in our Anatomie.

The vessels of
the braine
broken by the
commotion
thereof.

signes.

Celsus.

The cause of
vomiting
when the head
is wounded.

But from hence proceeds the efflux of blood running betweene the scull, and membraines, or else betweene the membraines and braine; the blood congealing there, causeth vehement paine, and the eyes become blinde, vomitting is caused, the mouth of the stomacke suffering together with the braine; by reason of the Nerves of the sixt conjugation, which runne from the braine thither, and from thence are spread over all the capacitie of the ventricle; whence becomming a partaker of the offence it contracts it selfe, and is presently as it were overturned; whence first, these things that are contained therein are expelled, and then such as may flow, or come thither from the neighbouring and commune parts, as the Liver and Gall; from all which choler, by reason of its naturall levity and velocity, is first expelled and that in greatest plenty; and this is the true reason of that vomiting, which is caused and usually followes upon fractures of the scull and concussions of the Braine.

Within a short while after inflammation seizes upon the membranes and braine it selfe, which is caused by corrupt and putrid blood proceeding from the vessels broken

ken by by the violence of the blow, and so spread over the substance of the braine. Such inflammation communicated to the heart, and whole body by the continuation of the parts, causes a feaver. But a feaver, by altering the braine causes Doting; to which if stupidity succeed; the Patient is in very ill case, according to that of *Hippocrates*; Stupidity, and doting, are ill in a wound, or blow upon the head. But if to these evils, a sphacell, and corruption of the braine ensue, together with a great difficulty of breathing, by reason of the disturbance of the Animall facultie, which from the braine imparts the power of moving to the muscles of the Chest, the instruments of respiration, then death must necessarily follow.

Aphor. 14, sect. 7

A great part of these accidents appeared in King *Henry* of happy memory, a little before he dyed. He having set in order the affaires of France, and entered into amitie with the neighbouring Princes, desirous to honour the marriages of his daughter, and sister, with the famous and noble exercise of Tiltting, and hee himselfe running in the Tilt-yard, with a blunt lance received so great a stroake upon his brest, that with the violence of the blow, the visour of his helmet flew up, and the trunchion of the broken Lance, hit him above the left eye-brow, and the musculous skinne of the fore-head was torne even to the lesser corner of the left eye, many splinters of the same trunchion being stricke into the substance of the fore mentioned eye, the bones being not touched or broken; but the braine was so moved and shaken, that he dyed the eleventh day after the hurt. His scull being opened after his death, there was a great deale of blood found betweene the *Dura*, and *Pia Mater*, poured forth in the part opposite to the blow, at the middle of the future of the hinde part of the head; and there appeared signes by the native colour turned yellow, that the substance of the braine was corrupted, as much as one might cover with ones thumb. Which things caused the death, of the most Christian King, and not onely the wounding of the eye, as many have falsly thought. For wee have seene many others, who have not dyed of farre more greevous wounds in the eye:

A History,

What was the necessary cause of the death of King Henry the second of France,

A History,

The history of the Lord Saint *Iohn* is of late memory: he in the Tilt-yarde, made for that time before the Duke of *Guises* house, was wounded with a splinter of a broken Lance, of a fingers length and thickenesse, through the visour of his Helmet, it entering into the Orbe under the eye, and peircing some three fingers bredth deepe into the head; by my helpe and Gods favour hee recovered, *Valeranus* and *Duretus* the Kings Physitions and *James* the Kings Chirurgeon assisting me.

A History,

What shall I say of that great and very memorable wound of *Francis* of *Lorraine* the Duke of *Guise*? He in the sight of the City of *Bologne* had his head so thrust thorough with a Lance, that the point entering under his right eye by his nose, came out at his necke betweene his eare and the *vertebra*, the head or Iron being broken and left in by the violence of the stroke, which stuck there so firmly, that it could not be drawn or plucked forth, without a paire of Smiths pincers. But although the strength & violence of the blow was so great, that it could not be without a fracture of the bones, a tearing and breaking of the Nerves, Veines, Arteries and other parts; yet the generous Prince by the favour of God recovered.

By which you may learne, that many die of small wounds; and other recover of great, yea very large and desperate ones. The cause of which events is chiefly and primarily to be attributed to God, the author and preserver of mankind; but secondarily to the variety and condition of temperaments. And thus much of the commotion or concussion of the braine; whereby it happens that although all the bone remains perfectly whole, yet some veines broken within by the stroke, may cast forth some blood upon the membranes of the braine, which being there concreate may cause great paine, by reason whereof it blindes the eyes; if so be that the place can be found against which the paine is, and when the skinne is opened, the bone looke pale, it must presently be cut out, as *Celsus* hath written. Now it remains, that we tell you how to make your prognostickes, in all the forementioned fractures of the scull.

Why some die of small wounds and others recover of great,

CHAP. X.

Of Prognostickes to be made, in fractures of the scull.

Hippoc. de vul.
cap.

EE must not neglect any wounds in the head, no not these which cut or bruise but onely the hairy scalpe; but certainly much lesse, these which are accompanied by a fracture in the scull; for oft times all horride symptomes follow upon them, and consequently death it selfe, especially in bodies full of ill humors, or of an ill habite, such as are these which are affected with the *Lues venerea*, leprosie, dropsie, Pthificke and consumption; for in these, simple wounds are hardly or never cured; for union is the cure of wounds, but this is not performed, unlesse by strength of nature, and sufficient store of laudible blood: but those which are sicke of heeticke feavers and consumptions, want store of blood: and those bodies which are replete with ill humors, and of an ill habite have no afflux or plenty of laudible blood: but all of them want the strength of nature; the reason is almost the same in those also which are lately recovered of some disease.

Whether the
wounds of
children, or old
people are bet-
ter to heale.

Those wounds which are brused are more difficult to cure, than those which are cut. When the scull is broken, than the continuity of the flesh lying over it must necessarily be hurt & broken, unlesse it be in a *Resenitus*. The bones of children are more soft, thin and replenished with a sanguine humidity, than those of old men, and therefore more subject to putrefaction; Wherefore the wounds which happen to the bones of children, though of themselves, and their owne nature they may be more easily healed, (because they are more soft, whereby it comes to passe, that they may bee more easily agglutinated, neither is there fit matter wanting for their agglutination by reason of the plenty of blood laudible both in consistence and quality) than in old men, whose bones are dryer and harder, and so resist union, which comes by mixture, and their blood is serous, and consequently a more unfit bond of unitie and agglutination; yet oft times through occasion of the symptomes which follow upon them, that is putrefaction and corruption, which sooner arise in a hot and moyst body, and are more speedily encreased in a soft and tender, they usually are more suspected and difficult to heale.

The Patient lives longer of a deadly fracture in the scull, in Winter than in Summer, for that the native heat is more vigorous in that time than in this; besides, also the humors putrifie sooner in Summer, because unnaturall heat is then easily enflamed and more predominant, as many have observed out of *Hippocrates*.

Aph. 15, sect. 1.

The Wounds of the braine and of the *Meninges* or membranes thereof are most commonly deadly, because the action of the muscies of the chest, and others serving for respiration, is divers times disturbed & intercepted, whence death insues. If a swelling happening upon a wound of the head presently vanish away, it is an ill signe, unlesse there be some good reason therefore, as blood-letting, purging, or the use of resolving locall medicines, as may be gathered by *Hippocrates* in his Aphorismes. If a feaver ensue presently after the beginning of a wound of the head, that is, upon the fourth or seaventh day, which usually happens, you must judge it to bee occasioned by the generating of Pus or Matter, as it is recited by *Hippocrates*. Neither is such a feaver so much to be feared, as that which happens after the seaventh day, in which time it ought to be determinated; but if it happen upon the tenth or foureteenth day with cold or shaking, it is dangerous, because it makes us conjecture that there is putrefaction in the braine, the *Meninges*, or scull, through which occasion it may arise, chiefly if other signes shall also concur, which may shew any putrefaction, as if the wound shall be pallide and of a faint yellowish colour, as flesh looks after it is washed.

Aphor. 65, sect. 5

Aph. 47, sect. 2.

Wounds which
are dry, rough,
livide and black
are evill,

For, as it is in *Hippocrates Aphorif. 2. sect. 70* It is an ill signe if the flesh looke livide, when the bone is affected; for that colour portends the extinction of the heare, through which occasion, the lively, or indifferently red colour of the part, faints and dyes, and the flesh thereabouts is dissolved into a viscid Pus or filth.

Com-

Commonly another worse affect followes hereon, wherein the wound becomming withered and dry, lookes like salted flesh, sends forth no matter, is livide and blacke, whence you may conjecture, that the bone is corrupted, especially if it become rough, whereas it was formerly smooth and plaine; for it is made rough when *Caries* or corruption invades it; but as the *Caries* encreases, it becomes livide and blacke, sanious matter withall sweating out of the *Diploe*, as I have observed in many: all which are signes that the native heat is decayed, and therefore death at hand; but if such a feaver be occasioned from an *Erysipelas* which is either present or at hand, it is usually lesse terrible. But you shall know by these signes, that the feaver is caused by an *Erysipelas* & conflux of cholericke matter; if it keepe the forme of a Tertian, if the fit take them with coldnes and end in a sweat; if it be not terminated before the cholerike matter is either converted into Pus or else resolved; if the lips of the wound be somewhat swollne, as also all the face; if the eyes be red and fiery; if the necke and chappes bee so stiffe, that he can scarce bend the one, or open the other; if there be great excelsse of biting and pricking paine, and heate, and that farre greater than in a *Phlegmon*. For such an *Erysipelous* disposition generated of thinne and hot blood, chiefly assailes the face, and that for two causes.

The signes of a feaver caused by an *Erysipelas*.

The first is, by reason of the naturall levity of the cholericke humor; the other because of the rarity of the skinne of these parts.

Why an *Erysipelas* chiefly assailes the face.

The cure of an *Erysipelas* on the face.

The cure of such an affect must be performed by two meanes, that is, evacuation, and cooling with humectation. If choler alone cause this tumor, we must easily be induced to let blood, but we must purge him with medicines evacuating choler. If it be an *Erysipelas phlegmonodes*, you must draw blood from the Cephalicke veine of that side, which is most affected, alwayes using advise of a phisition. Having used these generall meanes, you must apply refrigerating and humecting things, such as are the juice of Night-shade, Houfleeke, Purslaine, Lettuce, Navell wort, Water Lentill, or Ducks-meate, Gourdes; a liniment made of two handfulls of Sorrel boiled in faire water, then beaten and drawne through a searse, with ointment of Roses, or some *unguent*. *Populeon* added thereto, will bee very commodious. Such and the like remedies must be often and so long renewed untill the unnaturall heat be extinguished. But we must be carefull to abstaine from all unctuous and oily thing, because they may easily be enflamed, and so increase the disease. Next we must come to resolving medicines, but it is good when anything comes from within, to without; but on the contrary it is ill, when it returns from without inwards, as experience and the Authority of *Hippocrates* testifie: If when the bone shall become purulent, pustles shall breake out on the tongue, by the dropping downe of the acride filth or matter by the holes of the pallate upon the tongue, which lyes under. Now when this symptome appeares, few escape. Also it is deadly when one becomes dumbe and stupid, that is, Apolecticke by a stroake or wound on the head; for it is a signe that not onely the bone, but also the braine it selfe is hurt. But oft times the hurt of the Braine proceeds so farre, that from corruption it turnes to a Sphacell, in which case, they all have not onely pustles on their tongues, but some of them dye stupide and mute, other some with a convulsion of the opposite part; neither as yet have I observed any which have dyed with either of these symptomes, by reason of a wound in the head, who have not had the substance of their braine tainted with a Sphacell, as it hath appeared when their skulls have beene opened after their death.

Why oily things must not be used in an *Erysipelas* of the face.

Aph. 25, sect. 6

Deadly signes in wounds of the head.

CHAP. XI.

Why, when the braine is hurt by a wound of the head, there may follow a Convulsion of the opposite part.

Any have to this day enquired, but as yet as farre as I know it hath not bin sufficiently explained, why a convulsion in wounds of the head seizes on the part opposite to the blow. Therefore I have thought good to end that controversie in this place. My reason is this, that kinde of Symptome happens in the sound part by reason of emptinesse and

A convulsion is caused by drynesse.

A twofold
cause of con-
vulsive
dryness,

dryness; but there is a twofold cause, and that wholly in the wounded part, of this emptiness and dryness of the sound or opposite part; to wit, paine, and the concurrence of the spirits and humors thither by the occasion of the wound, and by reason of the paines drawing and natures violently sending helpe to the afflicted part.

The sound part exhausted by this meanes both of the spirits and humors, easily falls into a Convulsion.

Lib. 4. de usu
partium,

For thus *Galen* writes; God the creatour of nature, hath so knit together, the triple spirituous substance of our bodies, with that tie, and league of concord, by the productions of the passages; to wit of Nerves, Veines, and Arteries, that if one of these forsake any part, the rest presently neglect it, whereby it languisheth, and by little, and little dyes, through defect of nourishment. But if any object that nature hath made the body double, for this purpose, that when one part is hurt, the other remaining safe and sound, might suffice for life and necessity: but I say, this axiome hath no truth in the vessels and passages of the body. For it hath not every where doubled the vessels, for there is but one onely veine, appointed for the nourishment of the braine, and the membranes thereof, which is that they call the *Torcular*, by which when the left part is wounded, it may exhaust the nourishment of the right and sound part, and though that occasion cause it to have a convulsion, by too much dryness; Verily it is true, that when in the opposite parts, the muscles of one kinde are equall in magnitude, strength, and number, the resolution of one part, makes the convulsion of the other by accident; but it is not so in the braine.

For the two parts of the braine, the right and left, each by its selfe performs that which belongs thereto, without the consent, conspiracy, or commerce of the opposite part; for otherwise it should follow, that the Palsie properly so called, that is of halfe the body, which happens by resolution, caused either by mollification or obstruction residing in either part of the braine, should inferre together with it a Convulsion of the opposite part. Which notwithstanding dayly experience convinces as false. Wherefore wee must certainly thinke, that in wounds of the head wherein the braine is hurt, that inanition and want of nourishment are the causes, that the sound and opposite part suffers a convulsion.

Opinion of
Galen.

Francis Dalechamps in his French Chirurgery renders another reason of this question; That, (saith he) the truth of this proposition may stand firme and ratified, we must suppose, that the convulsion of the opposite part mentioned by *Hippocrates*, doth then onely happen, when by reason of the greatnesse of the inflammation in the hurt part of the braine, which hath already inferred corruption; and a Gangrene to the braine and membranes thereof, and within a short time is ready to cause a sphacell in the scull, so that the disease must be terminated by death; for in this defined state of the disease, and these conditions, the sense and motion must necessarily perish in the affected part, as we see it happens in other Gangrenes, through the extinction of the native heate. Besides, the passages of the animall spirit must necessarily bee so obstructed by the greatnesse of such an inflammation or phlegmon, that it cannot flow from thence to the parts of the same side lying there under, and to the neighbouring parts of the braine; and if it should flow thither, it will be unprofitable to carry the strength and facultie of sense and motion, as that which is infected and changed by admixture of putred and Gangrenous vapours. Whereby it cometh to passe, that the wounded part destitute of sense, is not stirred up to expell that which would be troublesome to it, if it had sense; wherefore neither are the Nerves thence arising seased upon, or contracted by a Convulsion.

It furthermore comes to passe, that because these same nerves are deprived of the presence and comfort of the animall spirit, and in like manner the parts of the same side, drawing from thence their sense and motion are possessed with a palsie; for a palsie is caused either by the cutting or obstruction of a Nerve, or the madefaction, or mollification thereof by a thinne and watry humor, or so affected by some vehement distemper, that it cannot receive the Animall spirit.

But for the opposite part and the convulsion thereof, it is knowne and granted by all, that a convulsion is caused either by repletion which shortens the Nerves by distending them into breadth, or by inanition, when as the native and primitive

heate

heate of the Nerves being wasted, their proper substance becoming dry is wrinckled up and contracted; or else it proceeds from the vellication, and acrimonie of some vapour, or sanious and biting humor, or from vehemencie of paine. So wee have knowne the falling sicknesse caused by a venenate exhalation carried from the foote to the braine. Also wee know that a convulsion, is caused in the puncture of the Nerves, when as any acride and sanious humor is shut up therein, the orifice thereof being closed; but in wounds of the Nerves when any Nerve is halfe cut, there happens a convulsion by the bitternesse of the paine.

But verily in the opposite part, there are manifestly two of these causes of a convulsion; that is to say, a putride and carionlike vapour, exhaling from the hurt, and Gangrenate part of the braine; and also a virulent acride and biting *Sanies*, or filth, sweating into the opposite sound part, from the affected and Gangrenous; the malignitie of which *Sanies*, *Hippocrates* desirous to decipher, in reckoning up the deadly signes of a wounded head, hath expressed it by the word *Ichor*; and in his booke of fractures he hath called this humor *Dacryodes et non Pyon*. [*that is, weeping and not digested.*] Therefore it is no mervaille if the opposite and sound part endewed with exquisite and perfect sense, and offended by the flowing thereto of both the vaporours and sanious matter, using its own force, contend and labour as much as it can, for the expulsion of that which is trouble somethereto. This labouring or concussion is followed (as we see in the falling sicknesse) by a convulsion, as that which is undertaken in vaine, death being now at hand; and nature over-ruled by the disease. Thus (saith *Dalechampius*) must we in my judgement determine of that proposition of *Hippocrates* and *Avicen*.

But he addes further, in wounds of the head, which are not deadly, practitioners observe that sometimes the hurt part is taken with the palsie, and the sound with a convulsion; otherwhiles on the contrary, the wounded part is seazed by a Convulsion and the sound by a Palsie; otherwhiles both of them by a convulsion or Palsie; and somewhiles the one of them by a convulsion or Palsie, the other being free from both affects; the causes of all which belong not to this place to explaine. Thus much *Dalechampius*.

CHAP. XII.

A Conclusion of the deadly signes in the Wounds of the head:

NOW that we may returne to our former discourse, you may certainly foretell the patient will dye; when his reason and judgement being perverted, hee shall talke idly, when his memory failes him; when he cannot governe his tongue, when his sight growes darke and dimme, his eares deafe, when he would cast himselfe headlong from his bed, or else lyes therein without any motion; when he hath a continuall feaver with a *delirium*, when the tongue breakes out in pustles, when it is chopt, and become blacke, by reason of too much drynesse; when the wound growes dry, and casts forth little or no matter, when as the colour of the wound which was formerly fresh, is now become like salted flesh yellow and pale; when the Urine, and other excrements are supprest; when the Palsie, convulsion, apoplexie, and lastly often sowning, with a small and unequall pulse, invade him. All such signes sometimes appeare presently after the wound, otherwhiles some few dayes after; therefore when as the braine is hurt and wounded by the violence of the incision, or fissure, of the contusion, compression, puncture, concussion or any other fracture, the forementioned signes appeare presently in the first dayes; but when they doe not appeare till many dayes after the blow, you may know that they rise and appeare, by reason of an inflammation and phlegmon in the braine, occasioned by the putrefaction of the blood poured forth upon it.

The signes of a deadly wound from the depraved faculties of the minde,

From habite of the body,

From the signs that such signes appeare,

But we must observe this by the way, which also belongs to the prognostickes, that flesh is easily regenerated, and restored in all parts of the head, except in that part of the forehead, which is a little above that which lyes betweene the eye-browes, so that

Celsus lib. 8. c. 9.

that it will be ulcerated ever after, and must be covered with a plaster. I beleeve that, in that place there is an internall cavity in the bone, full of ayre which goes to the five-like bones of the nose, by which the growth of flesh may be hindered; or else that the bone is very dense or compact in that place, so that there can scarce sufficient juice sweat forth, which may suffice for the regeneration of flesh; adde hereunto a great conflux of excrements flowing to this ulcer, which should otherwise bee evacuated by the eyes and nose, which hinder by that meanes the drynesse of the ulcer, and consequently the healing thereof.

Hence certainly it comes to passe, that if you desire the patient thus affected to breathe, shutting his mouth and nose, the ayre or breath will come forth of the ulcer with such force, as it will easily blow forth a lighted candle of an indifferent bignesse held thereto. Which thing I protest, I observed in a certaine man, whom I was forced to trepan in that place, by reason the bone of the forehead was broken and depressed.

CHAP. XIII.

Of salutarie signes in wounds of the head.

BVt on the contrary these are salutory signes, when the patient hath no feaver, is in his right minde, is well at the application or taking of any thing, sleepest well, hath his belly soluble, the wound lookes with a fresh and lively colour, casts forth digested and laudible matter, the *Cassa Meninx* hath its motion free and no way hindered.

When the patient
is out
of danger,

Yet we must note, which also is observed by the Ancients and confirmed by experience, that we must thinke none past danger, and free from all chance, untill the hundreth day be past. Wherefore the Phytitian ought so long to have a care of his patient, that is, to consider how he behaves and governes himselfe in meate, drinke, sleepe, venerie and other things.

The patient
must beware
of cold,

But let the Patient diligently avoyd and shunne cold, for many when they have beene cured of wounds of the head, by carelesse taking cold have beene brought into danger of their lives. Also you must know that the *Callus* whereby the bones of the scull are knit together, requires almost the space of fortie or fifty dayes to its perfect coagmentation and concretion. Though in very deed one cannot set downe a certaine number of dayes, by reason of the variety of bodies, or tempers. For it is sooner finished in young men, and more slowly in old; And thus much may serve for prognostickes. Now will we treat as breecely and perspicuously as we can of the cure both in generall and particular; wherefore beginning with the generall we will first prescribe a convenient diet by the moderate use of the fixe things not naturall.

CHAP. XIII.

Of the generall cure of a broken skull, and of the Symptomes usually happening thereupon.

How the ayre
ought to be.

The first cure must bee, to keepe the patient in a temperate aire; and if so bee, that it bee not such of it selfe and its owne proper nature, it must be corrected by Art. As in winter he must have a cleare fire made in his chamber, lest the smoake cause sneezing and other accidents; and the windowes and doores must be kept shut to hinder the approach of the cold ayre and winde. All the time the wound is kept open to bee drest, some body standing by shall hold a chafendish full of coales or a heated Iron barre over the wound, at such a distance, that a moderate heate may passe thence to the wound; and the frigidty of the encompassing ayre may be corrected by the breathing of the diffused heate. For cold according to the opinion of *Hippocrates*, is an enemy to the Braine, Bones, Nerves, and spinall marrow; it is also hurtfull to ulcers, by suppressing their excrements, which suppress doe

aphor. 18. sec. 2.

doe not onely hinder suppuration, but also by corrosion makes them sinuous. Therefore *Galen* rightly admonisheth us, to keep cold from the braine, not only in the time of Trepaning, but also afterwards. For there can no greater, nor more certaine harme befall the fractured skull, than by admitting the aire, by such as are unskilfull. For if the ayre should be hotter than the braine, then it could not thence be refrigerated; but if the braine should be layd open to the ayre, in the midst of Summer, when it is at the hottest, yet would it be refrigerated, and unlesse it were releevd with hot things, take harme: this is the opinion of *Galen*, whereby you may understand that many who have their skulls broken, dye more through default of skill in the curing, than by the greatnesse of the fracture.

Lib. 2, de usu
part. ca. 2.

The Aire
though in sum-
mer is colder
than the braine.

But (when the wound is bound up with the pledgets, clothes, and rowlers as is fit) if the ayre chance to be more hot, than the patient can well endure, let it be amended by sprinkling, and strowing the chamber with cold water, oxycrate, the branches of Willows and Vine. Neither is it sufficient to shunne the too cold ayre, unlesse also you take heed of the over light, chiefly untill such time as the most feared and malignant symptomes are past.

For a too great light dissipates the spirits, encreases paine, strengthens the feaver and symptomes. *Hippocrates* wholly forbids wine, therefore the patient in steed thereof must drinke, Barly water, faire water boyled and tempered with Iulep of Roses, syrupe of Violets, vinegar and the like: water wherein bread crummes have beene steeped, water and sugar with a little juyce of Lemons, or pomecitron added thereto, and such like as the abilitie and taste of the patient shall require. Let him continue such drinckes, untill he be free from malignant symptomes, which usually happen within foureteene dayes.

The discom-
modities of too
much light.

What his drinck
must be.

His meat shall be pappe, ptisan, shunning Almond milkes; (for Almonds are sayd to fill the head with vapours and cause paine) stued damaske Prunes, Raisons and Currance, seasoned with sugar, and a little cinamon (which hath a wonderful power to comfort the stomack, and revive and exhilarate the spirits) Chickens, Pidgeons, Veale, Kid, Leverers, birds of the fields, Pheasons, blacke-birds, Turtles, Partridges, Thrushes, Larkes and such like meates of good digestion, boiled with lettuce, purslane, sorrell, borage, buglosse, succory, endive and the like, are thought very convenient in this case. If he desire at any time to feed on these meates roasted, he may, only dipping them in verjuice, in the acide juices of Oranges, Citrons, Lemons, or Pomegranets, some times in one, and sometimes in another, according to his taste and ability. If any have a desire to eate fish, he must make choyce of Troutes, Gudgeons, Pikes and the like, which live in running and cleare waters, and not in muddy; hee shall eschew all cold sallets and pulse, because they flye up and trouble the head: it will be convenient after meate to use common drige powder; or Aniseed, Fennell-seed or Coriander cornfits, also conserve of Roses, or Marmilate of Quinces to shut up the orifice of the Ventricle, lest the head should bee offended with vapours arising from thence.

Almonds en-
crease the paine
of the head.

What fish he
may eate.

Children must eate often, but sparingly; for children cannot fast so long as those which are elder, because their naturall heate is more strong, wherefore they stand in neede of more nourishment; so also in winter all sorts of people require more plentifull nourishment, for that then their stomackes are more hot than in Summer.

Apher 13. 6.
14. sect. 1.

When the foureteenth day is past, if neither a feaver, nor any thing else forbid, hee may drinke wine moderately, and by little and little, encrease his dyet, but that respectively to each ones nature, strength and custome. He shall shunne, as much as in him lyes, sleepe on the day time, unlesse it happen that a *Phlegmon* seaze upon the braine or *Meninges*. For in this case it will bee expedient to sleepe on the day time, especially from morning till noone, for in this season of the day, as also in the spring blood is predominant in the body, according to the opinion of *Hippocrates*. For it is so vulgarly knowne, that it need not be spoken, that the blood when wee are awake is carryed into the habite and surface of the body; but on the contrary by sleepe it is called into the noble parts, the Heart and Liver. Wherefore if that the blood by the force of the Sunne casting his beames upon the earth, at his rising is carryed into the habite of the body, should againe bee more and more diffused by the strength

Apher. 15, sect. 2

Why sleepe up-
on the day-time
is good for the
braine being
enflamed.
Lib. 2. Epidem.

The discom-
modities ensu-
ing immoder-
ate Watching.

strength and motion of watching, the inflammation in the braine and *Meninges* would be much encreased. Wherefore it will bee better, especially then to stay by sleepe the violence of the blood running into the habite of the body, when it shall seeme to rage and more violently to affect that way. Watching must in like manner be moderate; for too much depraves the temper of the braine and of the habit of the whole body; it causes crudities, paines and heavinesse of the head, and makes the wounds dry and maligne.

Gal. Meth. 13.

Medicines pro-
curing sleepe.

But if the patient cannot sleepe by reason of the vehemencie of the inflammation of the braine and *Meninges*, *Galen* wishes, to wash, besmeare and annoint the head, nose, temples and eares with refrigerating and humecting things, for these stupifie, and make drowfie the Braine and membranes thereof, being more hot than they ought to be. Wherefore for this purpose let the temples bee anointed with *Unguentum populeon*, or *Unguentum Rosatum* with a little rose vinegar, or oxycrate; Let a sponge moistened in the decoction of white or blacke poppie seed, of the rinds of the rootes of Mandrages, of the seedes of Henbane, lettuce, purslaine, plantaine, night-shade and the like. He may also have a broath or barly creame, into which you may put an emulsion made of the seedes of white poppye, or let him have a potion made with ʒj. or ʒiʒ. of the syrupe of poppie, with ʒij. of lettuce water; Let the patient use these things 4 houres after meate, to procure sleepe. For sleepe doth much helpe concoction, it repaires the efflux of the triple substance caused by watching, alwageth paine, refresheth the weary, mitigates anger and sorrow, restores the depraved reason, so that for these respects it is absolutely necessary that the patient take his naturall rest.

The common
dities of sleepe.

If the patient shall bee plethoricke, let the plenitude be lessened by blood-letting, purging and a slender diet, according to the discretion of the Philition who shall oversee the cure.

But we must take heed of strong purgations, in these kindes of wounds, especially at the beginning, lest the feaver, inflammation, paine, and other such like symptomes be increased by stirring up the humors.

Lib. 4. Meth.

Phlebotomie according to *Galen's* opinion, must not onely be made respectively to the plenty of blood, but also agreeable to the greatnesse of the present disease, or that which is to come, to divert, and draw backe that humor which flowes downe, by a way contrary to that which is impact in the part; and which must be there evacuated, or drawne to the next. Wherefore for example, if the right side of the head be wounded, the Cephalicke veine of the right arme shall be opened, unlesse a great *Plethora* or plenitude cause us to open the *Basilica*, or Median, yet if neither of them can be fitly opened, the *Basilica* may bee opened, although the body is not plethoricke.

*Lib. de cur. per-
sanguinis Miss.*

The like course must be observed in wounds of the left side of the head; for that is farre better by reason of the straightnesse of the fibers, than to draw blood on the opposite side; in performance whereof you must have diligent care of the strength of the patient, still feeling his pulse, unlesse a Physition be present, to whose judgement you must then commit all that businesse. For the pulse is, in *Galen's* opinion, the certaintest shewer of the strength. Wherefore we must consider the changes and inequalities thereof, for as soone as we finde it to become lesser and more slow, when the fore-head beginnes to sweate a little, when he feelles a paine at his heart, when he is taken with a desire to vomit, or goe to stoole, or with yawning, and when hee shall change his colour and his lips looke pale, then you must stop the blood as speedily as you can; otherwise there will be danger lest hee poure forth his life together with his blood. Then he must bee refreshed with bread steeped in wine, and put into his mouth, and by rubbing his temples and nosethrilles with strong vinegar, and by lying upon his backe.

But the part shall bee eased and freed from some portion of the impact and conjunct humor by gently scarifying the lippes of the wound, or applying of Leaches. But it shall bee diverted, by opening these veines which are nighest to the wounded part, as the *Vena Puppis*, or that in the middest of the forehead, or of the temples, or these which are under the tongue; besides also cupping-glasses shal be applied

applied to the shoulders sometimes, with scarification, sometimes without; neither must strong, and long frictions with coarse clothes, of all the whole body, the head excepted, be omitted during the whole time of the cure, for these will be available, though but for this, that is, to draw backe and dissipate by insensible transpiration the vapours which otherwise would ascend into the head, which matters certainly in a body that lyes still and wants both the use and benefit of accustomed exercise, are much increased.

The use of
Fractures.

But it shall bee made manifest by this following and notable example, how powerfull blood-letting is, to lessen and mitigate the inflammation of the Braine, or the membranes thereof in wounds of the head. I was lately called into the suburbs of Saint German, there to visite a young man twenty eight yeeres old, who lodged there in the house of *John Martiall*, at the signe of Saint *Michael*. This young man, was one of the household servants of Master *Doncador*, the steward of the Lady *Admirall of Brion*. He fell downe headlong upon the left *Bregma*, upon a marble pavement, whence he received a contused wound, without any fracture of the scull, and being he was of a sanguine temperature, by occasion of this wound, a feaver tooke him on the seaventh day with a continuall *delirium* and inflammation of phlegmonous tumor of the wounded *Pericranium*. This same tumor possessing his whole head and necke by continuation and sympathy of the parts, was growne to such a bignesse, that his visage was so much altered, that his friends knew him not; neither could he speake, heare, or swallow any thing but what was very liquide. Which I observing, although I knew, that the day past, which was the eight day of his disease, he had foure saucers of blood taken from him by *Germaine Agace* Barber-surgion of the same suburbs; yet considering the integrity and constancie of the strength of the patient, I thought good to bleed him againe, wherefore I drew from him foureteene saucers at that one time; when I came to him the day after, and saw that neither the feaver, nor any of the fore mentioned symptoms were any whit remitted, or aswaged, I forthwith tooke from him foure saucers more, which in all made two & twenty; the day following when I had observed, that the symptoms were no whit lessened, I durst not presume by my owne onely advice, to let him the fourth time blood as I desired. Wherefore I brought unto him, that most famous Physition Doctor *Violene*, who as soone as he felt his pulse, knowing by the vehemencie thereof, the strength of the Patient, and moreover considering the greatnesse of the inflammation and tumor which offered its selfe to his sight, hee bid mee presently take out my Lancer and open a veine. But I lingred on set purpose, and told him, that hee had already twenty two saucers of blood taken from him: Then sayd he, Grant it be so, and though more have beene drawne, yet must we not therefore desist from our enterprize, especially seeing the two chiefe Indications of blood-letting yet remaine, that is, the greatnesse of the disease, and the constant strength of the Patient. I being glad of this, tooke three saucers more of blood, hee standing by, and was ready to take more but that he wished mee to differ it untill the after noone; wherefore returning after dinner I filled two saucers more, so that in all, this young man to his great benefit, lost twenty seaven saucers of blood at five times, within the space of foure dayes. Now the ensuing night was very pleasing to him, the feaver left him about noone, the tumor grew much lesse, the heat of the inflammation was aswaged in all parts, except in his eyelids, and the lappes of his eares, which being ulcerated cast forth a great quantitie of Pus or matter. I have recited this history purposely, to take away the childish feare which many have to draw blood in the constant strength of the patient, and that it might appeare how speedy and certaine a remedy it is in inflammations of the head and braine.

A History.

The two
chiefe Indica-
tions in blood
letting.

Now to returne from whence we digressed, you must note that nothing is so hurtfull in fractures and wounds of the head, as venery; not onely at that time the disease is present, but also long after the cure thereof. For great plenty of spirits are contained in a small quantity of seed, & the greatest part thereof flowes from the braine; hence therefore all the faculties, but chiefly the Animall, are resolved, whence I have divers times observed death to ensue in small wounds of the head, yea when they have beene agglutinated and united.

The discom-
modities of ve-
nery in
wounds of
the head.

All

How hurtfull
noyse is to the
fractures of
the skull.

A History.

All passions of the minde must in like sort be avoided, because they by contraction and dissipation of the spirits cause great trouble in the body and minde. Let a place be chosen for the Patient as farre from noyse as can be, as from the ringing of bells, beatings and knockings of Smithes, Coopers, and Carpenters, and from high-ways through which they use to drive Coaches; for noyse encreases paine, causes a fever, and brings many other symptomes.

I remember when I was at *Hisdin* at the time that it was besieged by the forces of Charles the fifth, that when the wall beaten with the Cannon, the noyse of the Ordinance caused grievous torment to all those which were sicke, but especially those that were wounded on their heads, so that they would say, that they thought at the discharging of every Cannon that they were cruelly stricken with staves on that part which was wounded; and verily their wounds were so angled herewith, that they bledde much, and by their paine and feavers encreased, were forced with much sighing to breathe their last.

Thus much may serve to be spoken of the cure in generall, now we will out of the monuments of the ancients, treat of the particular.

CHAP. XV.

*Of the particular cure of Wounds of the head, and of the
musculous skinne.*

Of a simple
wound of the
flesh and the
skinne.

Let us beginne with a simple wound, for whose cure the Chirurgion must propose one onely scope, to wit, Vnion; for unlesse the wound pierce to the skull, it is cured like other wounds of the fleshy parts of our bodies. But if it be compound, as many wayes as it is complicate, so many indications shew themselves. In these the chiefeest care must bee had of the more urgent order and cause.

A degestive
medicine.

A sarcoticke
Medicine.

An Epuloticke.

A History.

Therefore if the wound shall be simple and superficially, then the haire must first bee shaven away, then a plaister applied made of the white of an egge, bole Armenicke and Aloes. The following day you must apply *Emplastrum de lanna*, or else *de gratia Dei*, untill the wound be perfectly healed. But if it be deeper and penetrate even to the *Pericranium*, the Chirurgion shall not doe amisse, if at the second dressing he apply a digestive medicine (as they call it) which may be made of Venice Turpentine, the yolkes of egges, oyle of Roses and a little saffron, and that shall be used so long, untill the wound come to maturation; for then you must adde honey of Roses and Barly floure to the digestive. Hence must we passe to these medicines, into whose composition no oyle, or unctious bodies enters, such as this; *R. Terebinth. veneta ʒij. Syrupi rosar. ʒj. pul. aloes, Myrrha, & mastich. an ʒʒ.* Let them all be incorporated and made into an unguent, which shall be perfectly regenerated; then it must bee cicatrised with this following powder. *R. Aluminis combusti, corticis granatorum combusti. an. ʒj. Misceantur simul & fiat puluis:* but if the wound be so large that it require a suture, it shall have so many stiches with a needle, as need shall seeme to require.

Whilest I was at *Hisdin*, a certaine soldier, by falling of the earth whilest he undermined, had the Hairy scalpe so pressed downe even to the *Pericranium*, and so wholly separated from the beginning of the hinde part of his head, even to his forehead, that it hung over his face. I went about the cure in this manner; I first washed all the wound with wine, a little warmed, that so I might wash away the congealed blood mixed with the earth; then I dried it with a soft linnen cloth, and laid upon it Venice Turpentine mixed with a little *Aqua Vita* wherein I had dissolved some *Sanguis Draconis*, Mastich and Aloes; then I restored the hanging skinne to its former place, and there stayed it with some stiches being neither too strait, nor too close together, for feare of paine and inflammation, (which two chiefly happen whilest the wound comes to suppuration) but onely as much as should serve to stay it on every side, and to keepe forth the ayre, which by its entrance doth much harme to wounds:

the

What things
we must ob-
serve in sowe-
ing.

the lower sides of the wound, I filled with somewhat long and broad tents, that the matter might have passage forth. Then I applyed this following cataplasme to all the head. *R. farina hordei & fabarum an. ʒvj. olei rosati ʒiij, aceti quantum sufficit, fiat cataplasma ad formam pultis;* this hath a faculty to dry, coole, repell mitigate paine and inflammation, and stay bleeding.

I did not let him blood, because hee had bled much, especially at certaine arteries which were broken neere his temples; he being dressed after this manner grew well in a short time.

But if the wound bee made by the biting of a wilde beast, it must bee handled after another manner, as shall appeare by this following history. As many people on a time stood looking upon the Kings Lyons, who were kept in the Tilt-yard at Paris for the delight of King Henry the second, and at his charges: it happened that one of the fiercest of them broke the things wherein he was tyed, and leaping amongst the company, he with his pawes threw to the ground a Girl of some twelve yeeres old, and taking her head in his mouth, with his teeth wounded the muscous skinne in many places, yet hurt not the scull. She scarce at length delivered by the Master of the Lyons from the jawes of Death and the Lyon, was committed to the cure of Rowland Clares Chirurgion; who was there present by chance at the same time; some few dayes after, I was called to visite her; she was in a fever, her head, shoulders, brest and all the places where the Lyon had set his teeth, or nailes, were swelne, all the edges of the wounds were livide, and did flow with a watrish, acride, virulent, cadaverous, darke greene and stinking matter, so that I could scarce endure the smell thereof; she was also oppressed with pricking, biting and very great paine; which I observing, that old saying came into my minde which is: That all wounds made by the bitings of beasts, or of men also, doe somewhat participate of poyson. Wherefore there must principally great care bee had of the venenate impression left in the wounds by the nailes and teeth, and therefore such things must bee applyed, as have power to overcome poison. Wherefore I scarified the lips of the wounds in divers places, and applyed Leaches to sucke out the venenate blood, and ease the inflammation of the parts, then I made a Lotion of *Aegyptiacum*, Treacle and Mithridate after the following manner.

R. Mithrid. ʒj theriac. ʒij. aegyptiac. ʒʒ. dissolvantur omnia cum aqua vite, & Cardui ben. Let the wounds be fomented and washed with it warme; besides also Treacle and Mithridate were put in all the medicines which were either applyed or put into the wound; and also of the same with the conserves of Roses and Buglosse dissolved in the water of Sorrell and *Carduus benedictus*, potions were made to strengthen the heart and vindicate it from malignant vapours.

For which purpose also this following *Epithema* was applyed to the region of her heart. *R. aqua rosar. & nenuphar, an. ʒiiij. aceti scillitici ʒj. corallorum, santalorum alborum & rubrorum, rosar rub. pulveris spodi. an. ʒj. Mithridatij, theriace, an. ʒij. flo. cordial. pulveris atorum p. j. croci ʒj.* dissolve them altogether, make an Epitheme and apply it to the heart with a scarlet cloth or sponge, and let it bee often renewed. Verily she dressed after this manner, and the former remedies but once used, paine, inflammation and all the malignant symptoms were much lessened; to conclude she recovered, but lingred and was leane some two yeares after, yet at length she was perfectly restored to her health and former nature. By which you may understand, that simple wounds must be handled after another manner, than these which have any touch of poison.

But now that we may prosecute the other affects of the hairy scalpe, say that it is contused with a blow without a wound, that which must bee first and alway done, (that so the affect may better appeare, and the remedies which are applyed may take more effect) the haire must be shaven away, and at the first dressing a repelling medicine applyed, such as is this following *Oxyrhodinum*. *R. ol. ros. ʒiij. album. ovorum nu. ij. pulveris nucum cypressi, balanst. alumin. rocha, rosar. rub. an. ʒj.* Let them be all incorporated, and make a medicine for the former use, or in steed thereof, you may apply the cataplasme prescribed before consisting of *Farina hordei, fabarum, aceto & oleo rosaceo*. But such medicines must be often renewed, When the paine and defluxion

When we must not let blood in wounds.

A History.

The bitings of man and beasts are venenate.

Theriacall pickt Medicines.

A Cordiall Epithema.

The cure of the Hairy scalpe when it is contused.

A repelling medicine.

A discussing
Fomentation.

are appeased, wee must use discussing medicines for the dissipation of that humor which remaines impacted in the part; R *Emplastri de macilagin.* ʒij. *oxicroces, & emp. de meliloto, an.* ʒj. *olei chamam. & anethi, an.* ʒʒ. *malaxentur simul & fias emplastrum ad usum dictum.* Such a fomentation will also be good. R *vini rub. lib.* iiij. *lixiviij. com. lib.* ij. *nucis cupressi contus. nu.* x. *pul. myrtillorum ʒj. rosar rub. absinth. fol. salvia, majorana, stachados, florum chamam. melil. an. M. B. aluminis rocha, radices cyperi, calami aromatici an.* ʒʒ. *bulliant omnia simul,* and make a decoction to foment the grieved part. After somewhat a long fomenting it, whereby it may the better discusse, dry and exhaust the concrete humor; the head must be dried & more discussing things applied such as the Cerate described by *Vigo* called *de minio*, which hath an emollient and digestive faculty in this forme. R *Olei chamam. lilior. an.* ʒx. *olei massich. ʒij. pinguedinis vervecis lib.* j. *litharg. auri, ʒviij. minij ʒij. vini boni cyathum unum, bulliant omnia simul baculo agitando, primum quidem lento igne, mox vero luculentiore, donec tota massa colorem nigrum vel subnigrum contrahat; adde in fine coctura Terebinth. lib.* s. *pulveris massich. ʒij. gum. elemi. ʒj. cera quantum sufficit, bulliant rursus una ebullitione & fiat empl. molle.* But if the humor be not thus discussed, but onely grow soft, then the tumor must be quickly opened, for when the flesh is inflamed and putrified through occasion of the contained humor, the bone under it putrifies also by the contagion of the inflammation and the acrimony of the matter falling upon the bone. When you have opened it, wash away the filth of the ulcer with this following detergentive medicine. R *syrapi ros. & absinth. an.* ʒj. *terebinth. ʒʒ. pul. iros, aloes, mastichis, myrrha, farina hordei an.* ʒʒ. In steed hereof if there be great putrefaction *Aegyptia*, either by it selfe, or mixt with an equall quantity of *Vnguentum apostolorum* may be put into the ulcer. When the ulcer is cleansed it will be time to use scarotike and cicatrizing medicines.

dicines.

CHAP. XVI.

Of the particular cure of a fractured or broken scull.

Why the *Pericranium*
hath such ex-
quisite sense.

IF the scull be broken, so that it be needefull to trepan it, or to elevate and lift it up, or scrape it away, the musculous skinne being cut as wee formerly noted, the *Pericranium* shall be plucked from the scull, as wee sayd before; which because it can hardly bee done without great paine, by reason of its exquisite sense and connexion with the membranes of the braine, we must labour to mitigate the paine for feare of inflammation and other accidents. Therefore the first dressing ended and the corners of the wound drawn each from other; at the second dressing put to the wound, a digestive (as they terme it) made of the yolke of an egge, and oyle of Roses, but you must apply no humide thing to the bone, because we desire to keepe it sound and whole. For *Galen*s opinion is, that bared bones must not be touched with unctuous things, but rather on the contrary all dry things must bee applied to them, which may consume the superfluous humidity. Therefore we must lay some linte and the cephalicke powders which we shall hereafter describe, upon the bone we intend to preserve, and must have diligent care that it be not offended either by the the ayre, or touch of humide medicines. You must in Trepaning have a speciall care of the *Crassa Meninx*. For I have often observed a great quantity of blood to have flowed from some broken vessel, which adhered to the second Table: neither must we presently and forthwith stay such bleeding, but suffer it to flow according to the plenitude and strength of the patient; for thus the feaver, and together therewith the rest of the symptoms are diminished.

Gal. 6. Meth.

The bones are
offended with
the applicati-
on of humide
things.

Lib. de ulceris

For in the opinion of *Hippocrates*, in every greene wound it is good to cause often bleeding, except in the bellies; for thus the vehemencie of paine, inflammation and other accidents will bee lesse troublesome; also it is not amisse too for old ulcers to bleed much, for so they are freed from the burden of the impact humors. When you thinke it hath bled sufficiently, it may be stanchd with this following medicine described by *Galen*.

Gal. 6. Meth.

R *pulveris Aloes ʒij, thuris, mastiches an. ʒʒ. albumina ovorum nu. ij.*
agitentur

agitantur simul cum pilis leporinis minutim incisis, fiat medicamentum. When the bleeding is stayed, you shall for the aswaging of paine, droppe upon the *Meninx* some Pidgeons blood, yet warme by opening a Veine under the wing, then it shall bee strewed ouer with this following powder, *R Aloes, thuris, myrrha, sanguinis draconis an. ʒj. Misco, fiat pulvis subtilis.* Also you may make an irrigation with Rose Viegear, or some repelling medicine; such as is a cataplasme *ex farinis, & oleo rosaceo.* Which may bee applyed untill the fourth day to aswage and mitigate paine.

Vigoes Cerate will be of good use in this case, as that which in my opinion is most fit for fractures of the scull, because it drawes powerfully, resolves and dries moderately, and by reason of the smell refreshes the animall spirits, and strengthens the braine and membranes thereof, as you may easily perceive by things which enter into the composition thereof.

Vigoes Cerate
good for a
broken scull,

R Olei ros. Omph. resinae pini. gummi Elemi. an. ʒij. Mastiches ʒiʒ. pinguedinis vervecis castrati ʒiʒ. foliorum beton. caprifol. anthos an. M. j. ammoniaci ʒʒ. granorum tinctorum ʒx. liquata pinguedine terenda terantur, & ammoniacum simul cum aceto scillitico, eliquetur; deinde bulliant omnia simul in lib. ij. vini boni, lento igne usque ad consumptionem vini, deinde exprimantur; cum expressione addantur terebinth. Ven. ʒiiij. cera alba quantum sufficit, fiat cerotum molle ad usum prae dictum. Also let the necke, and all the spine of the backe bee annointed with a liniment, which hath force of mollifying the Nerves, lest they should suffer convulsion; such is this.

R Ruta, marrubij, roris mar. ebulor, salvia, herb. paralyf. an. M. s. rad. Ireos, cypervi, baccarum lauri. an. ʒj. florum chama. melil. hyperici, an. M. j. pistentur & macerentur omnia in vino albo per noctem, deinde coquantur in vase duplici cum olei lumbricorum, liliorum, de terebinthina, axungia, anseris & hum. an. ʒij usque ad consumptionem vini, postea colentur & in colatura adde terebinth. venet. ʒiiij. aqua vite ʒʒ. cera quantum sufficit. fiat linimentum secundum artem.

A liniment
good against
convulsions,

But when the paine is aswaged, we must abstaine from all such unctuous things, lest they make the wound become sordide and maligne, and putrifie the adjacent parts, and consequently the *Crassa Meninx* and scull; for the integrity of all parts may be preserved by their like, and such are dry things in a fracture of the scull. Wherefore all humide and oyely things must be shunned in the cure thereof, unless peradventure there shall bee some neede to mitigate paine and bring the humor to suppuration.

For according to *Galen*, we are oft forced for a time to omit the proper cure of the disease, so to resist the symptomes; furthermore *Hippocrates* would have us not to foment the scull, no not with wine, but if we doe, to let it be but with very little. *Vidius* interprets that little to be, when there is feare of inflammation; for wine if it be red, tart and astringent, hath a repressing refrigerating and drying facultie: for otherwise all wine although it heates and dries by its faculty, yet it actually humects and cooles, both which are very hurtfull in wounds of the head, or a fractured scull, especially when the bone is bare; for from too much cooling of the braine there is feare of a convulsion, or some other evill symptome.

Gal. 4. Meth.

How farre
humide things
are good for a
fractured scull;

Wherefore let this be ratified, that is, We must not use humide and unctuous medicines in wounds of the head, except for curing of an inflammation, or the mitigation of paine caused thereby. Therefore let the bared scull bee strewed with catagmaticke and cephalicke powders, (being so called by the ancients, for that they are convenient and good in fractures of the scull & the rest of the bones) for by their drynesse they consume the superfluous humiditie, and by that meanes helpe nature in the separating of the broken bones, and the regenerating of flesh. Such powders usually consist of such things as these ensuing.

Why Cepha-
licke or Ca-
tagmaticke
powders are
good.

Thus, *radix Iridos florent. farina Hordei, & Ervi, pulvis Aloes Hepaticae, sanguis Draconis, mastiche, Myrrha, rad. Aristolochiae, Gentianae*; and generally all such simples as have a drying and an abstergent faculty without biting; but you must not use these things before the paine, inflammation and apostumation bee past; that is then, when the membranes must be cleansed, the bones scaled, and the flesh generated.

When to used,

How to be
mixed when
they are to bee
applied to the
Meninges.

For the scull by how much it is the dryer, by so much it requires and more easily endures more powerfull and dryer medicines, than the *Dura Mater* or *Pericranium*, as that which in quicknesse of sense comes farre short of these two. Wherefore when you would apply the forementioned cephalicke pouders to the *Meninges*, they must be associated and mixed with honey, syrupe of roses or of wormewood and such other like, that so their too violently drying faculty may be alayed and tempered.

CHAP. XVII.

why we use Trepaning, in the Fractures of the scull.

Here are foure causes of this remedy. The first is, to raise up the depressed bones, and take forth their fragments, which presse upon the *Meninges*, or also upon the substance of the braine. The second is, that the *Sanies* or matter may bee evacuated, clensted, wasted, and dried up, which by the breaking of any vessell is poured forth upon the Membranes, whereby they are, and not they onely, but the Braine also is in great danger of corruption. The third is, for the fitter application of medicines, convenient for the wound and fracture. The fourth is, that so we may have something whereby we may supply the defect of a Repelling Ligature, and such an one as may hinder defluxions; for such a Ligature cannot take place here as it may in the other parts of the body, by reason of the Sphæricall or Round figure of the head, which doth not easily admit binding; and then the density and hardnesse of the interposed scull is a meanes that the vessells lying under it (by which usually the defluxion comes) cannot easily be bound with a rowler sufficiently to repell the running blood. And the externall vessells, (to whom the force of the Ligature may come) cannot bee bound without great paine, and danger of Inflammation.

Why a repell-
ing Ligature
cannot be
used in frac-
tures of the
Scull,

For by such a compression the pulsation of the Arteries would be intercepted, and the efflux of the fuliginous excrements which use to passe through the sutures of the scull, would be supprest, by reason of the constriction of these sutures.

Besides also, the blood would thus bee forced from the wounded part without, to within into the Membranes and Braine, whence paine, Inflammation, a Feaver, Abscesse, Convulsion, Palsie, Apoplexie, and lastly death it selfe would ensue.

And these are the chiefe causes, that Trepaning is necessary in fractures of the scull, and not so in the fractures of other bones.

How the pa-
tient must be
placed when
you Trepan
him.

But before you apply or put to your Trepan, the Patient must bee fitly placed or seated, and a double cloth must be many times wrapped about his head, and then his head must be so laid, or pressed upon a Cushion or pillow, that when you come to your operation, it may not sinke downe any further, but remaine firme and stedy.

Then you must stoppe the patients eares with Cotton-wooll, that so hee may not heare the noise made by the Trepan, or any other Instrument.

What to be
done before
the applicati-
on of the
Trepan.

But before you put to your Trepan the bone must be pierced with an Instrument, having a three square point, that so it may bee the more speedily and certainly perforated. The point thereof must be no bigger then the pin of the Trepan, that so the Trepan which is forthwith to bee applyed may stand the more firmer, and not play to and againe in too wide a hole.

The shape of this Instrument is not much different from a Gimblet, but that the point is three-square, and not twined like a screw; as you may perceive, by this following figure,

*A Gimblet or peircer to perforate the scull, before the setting
too of the Trepan.*

A. Shewes the handle.

B. The points which may be screwed and fitted into the handle.

CHAP. XVIII.

A description of Trepan.

Trepans are round sawes, which cut the bone circularly more or lesse according to their greatnesse; they must have a pinne standing in the middle a little further out than their teeth, so to stay and hold fast the Trepan that it stirre neither to this side nor that, untill it bee entred and you have cut through the first table at the least: then you must take forth the pinne, lest going quite through the bone, it may pricke or hurt the *Crasse Meninx*.

Wherefore when you have taken forth the pinne, you may safely turne it about untill you have cut through both the tables; Your Trepan must also have a cappe, or somewhat to engirt or encompasse them, lest no way hindred they cut more of the bone than we would, and in conclusion runne into the *Meninx*.

They must also be anointed with oyle, that so they may cut the more readily and gently; for thus Carpenters use to grease their sawes. But you must, during the time of the operation, often dippe them in cold water, lest the bone by attrition become too hot; for all hard solide bodies by quicke and often turning about, become hot; but the bone made more hot and dry, is altered and changeth its nature, so that after it is cut, more of it scales and falls away.

Now you must know that the bone, which is touched with the Trepan, or the Aire, alwayes casts off scales, for the speedier helping forwards; whereof, you must strew upon it pouders made of Rocket, Briony, wilde Coucumber and *Aristolochia* roots. When the bone is sufficiently scaled let this following powder be put upon it, which hath a faculty to cover the bone with flesh, and to harden it with drynesse convenient to its kinde.

R Pulver. Treos Illyrice, Aloes, Manna thuris, Myrrha, aristolochia an. 3j. Flesh being by this meanes generated, let it be cicatrized by strewing upon it the rindes of Pomegranats and Alome burnt.

Neither shal the Chirurgion forcibly take away these scales, but commit that whole worke to nature, which useth not to cast them off before that it hath generated flesh under them. For otherwise if he doe any thing rashly, hee brings new corruption to

The harme the bone receives by being heated with the Trepan.

What things hasten the scaling of the bone.

The bone must not be forcibly scaled.

the bone; as we shall more at large declare, when wee come to treat of the *Caries* or *Rottennesse* of bones.

A caution in
Trepaning.

He which useth the Trepan, must consider this, that the head is of a round figure, and also the Trepan cuts circularly, and therefore it is impossible to cut the bone so equally on every side, as if it were performed upon a plane body. Furthermore the thickness of the scull is not alike in all places; wherefore you must looke, and marke whether the Trepan goe not more deepe on one side than on the other, which you may doe by measuring it now and then with a pinne or needle; and if yee finde that it is cut deeper on one side, than on the other, you must presse downe the Trepan more powerfully upon the opposite part.

A safe and
convenient
Trepan.

But seeing there are many sorts of Trepan invented and expressed by many men, yet if you weigh and rightly consider them all, you shall finde none more safe, than that I invented, and have here delineated. For it cannot peirce one jot further into the scull, than he pleases that useth it, and therefore it cannot hurt either the *Meninges* or the *Braine*. An Iron head or cover stayes it as a barre, that it can penetrate no further than you shall thinke it requisite.

This head or Cover is to be drawne up and downe, and set higher and lower, as he which uses it shall thinke good, and so it will stay the Trepan that it shall not goe a haire bredth beyond your intended depth. So that henceforwards there shall be no Chirurgion, howsoever ignorant in the performance of his Art, which by the benefit of such a Trepan may not performe this operation without any danger or feare of danger of touching the *Dura Mater*; the hurting whereof, puts the life in jeopardy.

The figure of our Trepan opened and
taken in peeces.

The figure of the same Trepan fitted and
put together.

A. shewes the whole handle or Brace of the
Trepan.

B. The Cover or Cap of the Trepan.

C The female.

D.D. The screw pins which hold and stay the
female and Trepan.

E. The Trepan without his pinne.

F. The Trepan furnished with its pinne.

A. Shewes the Brace and Trepan fitted in
every point.

B. The place into which the Trepan is put
and fitted.

C.C.C. The upper end of the Trepan which is
to be fitted and put into the Braine.

D. The Trepan with its cover or cap upon it.

E. The female.

F. A screw pin by the twining whereof the
Trepan is fastened in the Brace.

G. Another screw pin which fastnes the female
closer to the Trepan.

H. The Three square point.

In stead of the other Trepan set forth by the Author, I have thought fit to give you the figure of that Trepan that is here most in use, and the fittest therefore, as it is set forth by Mr. Doctor *Crooke*.

A Terebellum or Gimblet consisting of three branches.

A Lentill-like cutting Scraper.

All these particulars of the Trepan taken in sunder, you may see united and fitted together in the other figure. But when you cannot bring out the bone which you have cut off with your Trepan; then you may take it forth with the *Terebellum* or Gimblet here exprest, that is, screwing the point thereof into the hole made by the threesquare pin; the handle of this Instrument may also serve in stead of a Levatorie.

When with the Gimblet you have drawne or taken forth that part of the scull which was cut away by the Trepan; if there shall bee any sharpe splinters in the second table, which may hurt and pricke the *Meninx*, when it is beaved up by the motion of the braine, they must be shaved away and planed with this Lentill fashioned scraper, being so called, because it hath the head thereof fashioned and smooth like a Lentill, lest being sharpe it should hurt and pricke the membrane in the smoothing thereof.

But if by reason of the thickestesse, the scull cannot bee cut with this Lentill-like scraper, you may use the cutting scrapers and a mallet. The mallet must be of leade, that so it may shake the braine as little as may be. But you must diligently with your mallets take forth the sharpe splinters, and peeces of the bone. But if the fractured part of the scull bee such, that it will not admit that section which is requisite for the bared bone, as when the fracture is upon the temporall muscle, or at the sutures; then in the stead of one Trepan, two or three must be applyed, if the necessity of the present case so require, and that within a very small compasse; but they must not bee applyed to the fractured part, but nigh thereto, as we shall shew more at large in the following chapter.

But the Trepan shall be applyed so neere to each other, that the ring of the second may be joyned with the ring of the first and third. But if a fracture shall happen to light upon a suture, then you must not apply a Trepan to it, but use two thereto on each side; he that shall doe otherwise, shall reare in sunder the nervous and membranous fibers, and also the veines and arteries by which the *Dura Mater* is fastned to the scull, and yeelds matter to the *Pericranium*. He which shall apply one Trepan, that

The use of a
Leaden Mal-
let.

Why a Tre-
pan must not
be applyed to
the sutures.

Why two
Trepan are
to be used to a
fractured su-
ture.

that is, but upon one side of the future, he shall not bee able to get forth all the *Sanies* which is fallen downe on both sides by reason of the partition of the *Crasa Meninx* which lyes betweene, and rises up by the futures of the scull.

To conclude, when for what cause soever we cannot make use of a Trepan, we may imploy this instrument, if so bee as much of the bone bee bared as is needfull. It is made in forme of a paire of Compasses, and by meanes of a screw may bee opened more or lesse as you please. You as need shall require may change the points, and put other in their places, for they may bee fitted to one side of the compasse with a screw.

A paire of cutting Compasses to cut forth the scull.

- A. Shewes the one legge of the cutting compasses, which as you carry it about cuts the scull.
- B. The screw which fastens the point to the legge of the compasses.
- C. C. Two different points which may bee screwed to the legge of the Compasses, as neede shall require.
- D. A great screw which fastens upon an Iron string, alongst which the one of the legges of the Compasse running, may bee widened and straitned as you please.

Moreover it is fit that the one legge of such cutting compasses should stand firme and steddly, whilest the other is drawne circularly to cut. Wherefore it is fit you have an Iron plate made full of little holes, wherein you may firmly stay that legge of the compasse, least it waver against your will; it is requisite that this plate be crooked, (because the head is round) that so it may be fitted to any part thereof.

A crooked Iron Plate fit to sustaine and hold steddly one legge of the Compasse upon the head.

Another

Another paire of Compasses of the like nature and use, which may be widened and straightened by a screw.

CHAP. XIX.

Of the places of the skull whereso you may not apply a Trepan.

If of all, you shal not apply a Trepan, to a bone that is so broken that it is wholly, or in the greater part thereof divided from the skull by the violence of the stroake, least by your weight and pressing of the Trepan, you force it downe upon Membrane.

A bone almost severed from the skull must not be Trepaned.

Secondly, you must not apply one to the fractured Sutures, for the reasons mentioned in the former chapter.

Thirdly, nor to that part of the forehead which is a little above the eye-browes, for these reasons we gave you before in the twelfth chapter. For there is in that place under the first table of the skull it selfe, a large cavities replenished with a certaine white and tough humor, as also with a certaine spirituouse and ayrie substance, placed there by nature, to prepare the aire which ascends to the braine by the Nose-thrills: unlesse the Chirurgion observe and be mindfull hereof, he may bee deceived, supposing this cavity to be an Effrature of the bone and a depression thereof.

A notable cavity in the forehead bone.

Fourthly, neither in the lowest parts of the skull, lest the marrowy substance of the Braine, by reason of its weight, should slide through the hole made by the Trepan.

Fifthly, neither to the *Bregma* bones of Children, as those which as yet have not acquired just soliditie, to endure the impression of a Trepan.

Sixtly, nor to the temples by reason of the Temporall muscle, the cutting whereof in the opinion of *Hippocrates* causes convulsion of the opposite part. For being cut athwart it looses its proper action, that is, to move and lift up the lower Jaw; but then the opposite Temporall muscle being whole and perfect, using its strength, (his Antagoniste suffering it, and not resisting or labouring any thing at all to the contrary) it drawes the same Jaw to it, whereupon the mouth and all the parts of the face are drawne awry, and suffer a Convulsion towards the sound part, the other being resolved according to *Hippocrates* his rule.

Lib. de Vul. can.

For as often as the muscles of one kinde are equall in number, magnitude and strength on each side, the resolution of the one part, causes the Convulsion of the other.

A rule out of Hippocrates.

Neither doth this danger alone arise from the cutting of the Temporall muscle, but also another, which is, that this muscle when we eate and speake, is in perpetuall motion, whereby it comes to passe, that being once cut, it is scarce ever united againe, besides also the commissure or joyning together of the stonie bones lye under it.

What discommodities arise from cutting the temporall muscle.

But by the second caution we are forbid to Trepan upon the sutures, moreover also

also many Veines, Arteries and Nerves are spread over the substance thereof, so that by cutting of them, there is danger of many and maligne symptoms, as paine, inflammation, a feaver, a convulsion not onely of the part it selfe, but also of the whole body, whence lastly death ensues.

Wherefore let no Chirurgeon be so foole hardy, as to attempt the cutting of this muscle, so to Trepan the bone which lyes under it, rather let him apply his Trepan above it, or on the side thereof, or as neere to the affected part as he can, as I did in a Gentleman caled Monsieur de la Breteſche.

A history.

He in the triumphant entrance of King Henry the second, into the Citty of Paris, was so hurt with a stone, that the *Os Petrosum* or scaly bone, was broken with the violence of the blow, and the temporall muscle was vehemently contused, yet without any wound. I being called the next day (viewing the manner of the hurt, and the condition of the wounded part) thought good to bring some Physitions, and Chirurgions with me to consult hereof, of whom when some thought it expedient presently to divide the Temporall muscle, that baring the bone we might apply a Trepan, and so take forth the broken bones: I on the contrary begun earnestly to withstand that opinion, citing that saying of Hippocrates, *ex libro de vulneribus Capitis*, wherein Chirurgions are forbidden to cut such muscles, for feare of the forementioned symptoms; also I cited experience, how that I had often observed all those which had this muscle cut, dyed with a convulsion; but that it should be farre better, that neere above the fracture the bone should be Trepaned, not touching the Temporall muscle at all if he could. When all of them at the last had inclined to my opinion, I presently divided the musculous skinn which was over the upper part of the fracture with a three cornered section: the day following which was the third of his disease I Trepaned him, and after I had done, some few dayes after, I tooke out some foure splinters of the broken bone; and I put in a plaine leaden pipe, by which (I wishing the patient ever when I dressed him to hold downe his head, to stoppe his mouth and his nose, and then strive as much as in him lay to put forth his breath) much sanious matter came forth, which was gathered betweene the scull and *Crasſa Meninx*. Other filth which stucke more fast, I washed out with a detergent decoction, injected with such a syring as is heere exprest; And I did so much, God blessing my endeavours, that at length he recovered.

A Plane leaden pipe for to carry forth
the Sanies gathered under
the scull.

A little syring fit to make injections
withall.

A history.

The like chance and fortune befell Monsieur de Pienne at the seige of Metz. For he as hee fought at the breach of the wall, had the bone of his Temples broken with a stone strucke out of the adjacent wall, by a peece of Ordinance shot from the Emperours campe; he presently fell downe with the blow, and cast blood out of his mouth, nose and eares, with much vomiting, and remained dumbe & as it were senselesse almost foureteene dayes, so that he knew none of the by-standers. He had often palpitations, and convulsive twitchings, and his face was swollne. His forehead bone was Trepaned at the side of the Temporall muscle by the hand of Peter Aubert the Kings Chirurgeon: and although on the 25. day, soft flesh, endued with exquisite sense grew out of the hole made with the Trepan, whose growth could not bee hindered by Catharticke powders, yet at the length he recovered.

The Ancients called this kinde of growing flesh a *Fungus* [i. a Mushrome] for that it is soft, and growes with a small roote and broad top like a mushrome: but it encreases and decreases, according to the plenty of the flowing matter, and industry of the Chirurgeon hindring by art the growth thereof.

This flesh stinkes exceedingly, they commonly call it *Ficus sancti Piacry* [i. the figge]

Figge of *S. Fiacye*.] This disease commonly hath its originall after this manner. Even as in the bodies of Trees from the excrements of nourishment, a certaine halfe putrid grosse and viscos humor sweats through the barke, and gathered together by little and little growes into a Mushrom, so blood melancholly both in temper and consistence, springs from the broken vessels of the scull and *Crassa Meninx*, which also is sent sometimes by nature for the necessary repairing of the flesh in these parts, whereupon a certaine *fungus* breedes, which in *Galens* opinion, favors or partakes of the nature and condition of the parts to which it growes; though in generall it bee of the nature of maligne warts, or excrescences. But for to take away such *Fungi*, you must apply medicines which have a specifick faculty to waste superfluous flesh; such are these which strongly dry, and gently waste and cate, such as this which follows.

The generatio
on of a *Fungus*.

R. Sabine ʒij. *ocra* ʒj. *pulverisentur simul*, *aspergatur caro excrescens*, or else. *R. Hermodactylorum combustorum* ʒss. make a powder for the same use. But if so be that this fungous flesh come to such growth, (as it often happens,) as to equall the bignesse of an egge, it must be tyed and strait twichted, close to the roote with a silken thred; and when it shall fall away by reason of this binding, the place must be strewed with the fore-mentioned powders, for so it will be more certainly cured, than with more acride cathartickes.

CHAP. XX.

Of the corruption and Caries, or rottennesse of the bones of the Head.

Here sometimes followes a corruption and Sphacell of the fractured bones of the scull upon wounds of the head; which happens either because they are touched by the ayre, which they are not sensible of; or for that the *Sanies* putrifying and detained under them, hath infected them with like putrifaction; or by the cure unskillfully handled, they by the rash application of suppurating and oyle medicines becoming more moyst, and so undergoing an unnaturall change of their proper complexion and native temper, as we shall shew more at large when we shall treat of the reason of the *Caries* in the *Lues venerea*. We shall know this unnaturall change and corruption, partly by sight, that is, when from white they become to be yellowish, livide and black; partly also by putting downe a probe; when as it meets with nothing smooth and slippery, but feelles rough in many places, and besides also when it enters and easily penetrates with a small thrusting downe into their substance, as if it were fungous. Yet this last signe may often deceive you, for I have diverse times observed rotten bones, which being bare had long suffered the injury of the ayre, to become so hard that a Trepan would scarce peirce them; for it is putride humidity which makes the bones soft and fungous; but the ayre by drying them exhausts this humiditie and lastly dries it, whence followes such contumacious hardnesse. This signe will bee farre more certaine, if the flesh which is growne upon the bone be more soft than is fit, loose and have little or no sense or feeling. You may correct and amend this corruption of the bone with cauteries as well actuall, as potentiall, or with the powders of Aloes, Gentian, *Aristolochia*, centaury, *cortex pini*, as,

Why when
the scull is
broken the
bones some-
times become
soule or rot-
ten.

The signes of
foulenesse of
the bone.

Corrupt
bones are
sometimes
hard.

R. radie. treos, Flor. aristolochia an. ʒj. *centaur.* ʒij. *corticis pini* ʒss. *Misce & fiat pulvis subtilissimus ossis inspergendus*. But if it be much corrupted, it must bee scraped forth with your Scalpra. And you must expect the falling or scalling of the corrupt bone from the sound, and not forcibly procure it; for otherwise the sound bone, which lyes under it, being as yet covered with no flesh growing over it, would be corrupted by the appulse, or touch of the ayre. Yet you shall by little and little gently move and shake rotten bones with your probe, that so they may more easily scale and with lesse trouble to nature. But note by the way, that the scalling of the bone which hath environed the Trepan, is commonly performed in the space of fortie or fifty dayes. So long also will that caused by the unusuall appulse or touch of

of the aire, or application of a Cautey, or the asperſion of Cephalicke powders; beſides alſo in the ſame number of dayes broken bones may be united and joyned together by a *Callus*, which is to them as a ſcarre, yet ſometimes ſooner, ſomewhiles latter according to the variety of the ages, tempers and habits of divers men.

The benefit
of a vulnerary
potion.

But if the *Caries* or *Rottenes* can neither by theſe fore mentioned remedies be overcome and amended, neither the looſed continuity agglutinated nor united, you muſt give the patient a vulnerary potion, for hence I have found happy ſucceſſe in many. But ſometimes not onely a certaine portion of the bone, is taken with a *Caries*, but alſo the whole is often ſeazed upon with ſphacell, and all falls out. For in *Hippocrates* opinion, *Lib. de vulneribus capitis*, the bone of the ſcull being broken falls from the ſound more or leſſe, according to the violence of the blow; which alſo is confirmed by experience.

A Hiſtory.

For which purpoſe I thinke good in this place to recite a Hiſtory, whereof I was an eye witneſſe, whilt I ſerved as Chirurgion in *Piemont* under the Marſhal de *Monteſan* (who was the Kings Leiſtenant there.) It happened that a Lackey of *Monſieur de Goulaines* came to me to be cured; he had the *Bregma* bone of the left ſide broken with a ſword, neither yet did the fracture come to the ſecond Table; a few dayes after his recovery the bone being agglutinated and united, it came to paſſe that a company of *Gaſcoine* ſouldiers his countreimen came to *Turin*, with whom one morning he eate plentifully Tripe fryed with Onions and ſpices, & drunke a great quantity of ſtrong wine. Whereupon he preſently fell into a continuall Feaver, and loſt his ſpeech and underſtanding; his head ſwelled, his eyes looked red and fiery and as though they would have ſtarted out of his head. Which things being conſidered, I let him blood, having firſt (by the Phyſirions advice) given him a Giſter, and applyed to his head ſuch things as were fit, and alſo I laboured with Frictions and Ligatures of the extreame parts to draw the humors downewards; yet for all this the part of the head which was formerly affected began to impoſtumat; which being opened, there came forth a great quantity of matter, and at the length the muſculous ſkinne and *Pericranium* ſincking downe, both the Tables of the ſcull became putrified and rotten, as you might know by their blackneſſe and ſtench. Now to take away this corruption, I applyed at certaine times actuall cauterics, both to amend the corruption and ſeparate that which was altered: but marke, after ſome months ſpace, a great number of wormes came forth by the holes of the rotten bones from underneath the putrified ſcull; which moved me to haſten the ſeparation and falling away of the putrid bones. Which being done, upon the very *Craſſa Meninx*, which is more ſtrange, in that place which nature had covered with fleſh, I obſerved three cavities of the largeneſſe of ones thumbe filled with wormes about the bigneſſe of a points tagge, with blacke heads, diverſly wrapped amongſt themſelves. The bone which nature ſeparated was of the bigneſſe of the palme of ones hand, ſo that it was ſtrange that ſo large a portion of the ſcull ſhould bee caſt off by nature, and yet the patient not dye thereof; for he recovered yet beyond all mens expectation, but after the agglutination of the wound the ſcarre remained very hollow according to the decree of *Hippocrates*. For fleſh doth not eaſily grow upon a *Callus*, becauſe it is a thing ſtrange and ſuppoſitious by nature; beſides, as a ſcarre is a thing more denſe than the ſkinne, ſo is a *Callus* than the bone, ſo that through the more compact ſubſtance thereof, the blood can neither freely, nor plentifully ſweat through for matter to regenerate fleſh. Hence it is, that whereſoever any portion of the ſcull is wanting, you may there by putting too of your hand perceive and feele the beating of the Braine, wherefore the ſcull muſt needes bee much weaker in that place. Now to helpe this infirmity, I wiſhed this Lackey to weare a Cap made of thicke leather, ſo more eaſily to withſtand externall injuries, and verily thereby he grew much better.

A great falling
away of a corrupt
rupt bone.

Aph. 45. Sect. 6

The covetous
craft of im-
poſtors.

Now I thinke good in this place to lay open the deceite and craft of ſome Impoſtors falſly ſtiling themſelves Chirurgions, who when they are called to cure wounds of the head, wherein any part of the ſcull is loſt, perſwade the patient and his friends, that they muſt put a plate of gold in the place of the ſcull which is wanting. Wherefore they hammer it, in the preſence of the patient, and turne it divers wayes and apply

apply it to the part, the better to fit it; but presently after they sliely convey it into their purses, and so leave the patient thus cosened. Others bragge that they are able to put the dried rinde of a gourd into the place of the lost bone, and fasten it on to defend the part; and thus they grossely abuse those which are ignorant in the Art. For this is to farre from being done that nature will not suffer nor endure so much as an haire, or any other small body to be shut up in a wound when it is cicatrized; neither is the reason alike of a leaden bullet which shot into the body lyes there for many yeeres without any harme to the patient; for although lead have a certaine familiarity with mans body, yet is it at length (unlesse the density of the opposed flesh, ligament, tendon, or some other such like substance hinder) thrust forth by nature impatient of all strange bodies. And thus much of the rottenesse and corruption of fractured bones; now must we speake of the discommodities which befall the *Meninges* by wounds whereby the scull is broken.

CHAP. XXI.

Of the discommodities which happen to the *Crasa Meninx* by fractures of the scull.

MAny discommodities chiefly happen to the *Crasa Meninx* by a fracture of the scull and rash Trepaning thereof; for it sometimes chanceth to be cut and torne. Agglutination is a remedy for this disease, which *Hippocrates* wishes to be procured with the juice of *Nepeta* [that is, of that calamint, which smells like Penny-royall] mixed with barley floure. In steed whereof this following powder having the like faculty may take place.

R. Colophon. ʒiij. Myrrha, aloes, mastiches, sanguinis Dracon. an. ʒj. croci, sarcocelle an. ʒʒ. misce & fiat pulvis subtilis. But to purge the blood and matter which is gathered and lyes betweene the *Crasa Meninx* and scull, you shall put in a Tent made of a ragge twined up some foure or five double, and steeped in syrupe of Roses or wormewood and a little *aqua vita*; for thus you shall presse downe both the *Crasa Meninx*, left lifted up by the accustomed and native pulsation of the braine, it should be hurt by the edges of the scull yet rough by reason of the sharpe splinters of the bone lately Trepaned, and give freer passage forth for the matter there contained. But as oft as you shall dresse the patient, you shall renew the forementioned Tent, untill all the matter be purged forth. And so often also you shall presse downe with the following instrument the *Dura Mater*, and bid the patient to strive to put forth his breath, stopping his mouth and nose, that so the matter may more easily be evacuated. This Instrument wherewith you shall hold downe the *Dura Mater*, must have the end round, polisht and smooth as it is here exprest.

Remedies for
the lacerated
Meninx.

A fit Instrument to presse and hold downe the *Dura Mater*, so to make way for the passage forth of the Sanies or Matter.

And let there be layd upon the *Dura Mater* strewed over with the formerly mentioned powder, a sponge moystened and wrung forth of a drying decoction made of aromaticke and cephalicke things, such as this which followes.

R. Fol. salvia, majoran. betonica, rosar. rub. absinth. Myrtil. florum chamem. melil. stachad. utriusque an. M. iij. ʒ. rad. cyperi, calam. aromaticos, caryophyllata; angelica, an. ʒʒ. bullians omnia secundum artem cum aqua fabrorum & vino rubro, fiat decoctio ad usum dictum. And in stead hereof you may use claret with a little *aqua vita*, that so the conteyned matter may be evacuated and dried up. A sponge is fitter for this purpose to draw than a linnen ragge or any other thing, both because it is good of its selfe to draw forth the humidity, as also for that by its softnesse it

A sponge fit
to foment
withall.

Lib. de Vuln. cap. yeelds to the pulsation of the Braine. Then apply to the wound and all the adjoining parts, an emplaster of *Diacalcitheos* dissolved with vinegar, or wine, or oyle of Roses, that so the plaster may be the more cold and soft. For in *Hippocrates* opinion, nothing which is any thing hevie or hard must be applyed to wounds of the head, neither must it be bound with too strait, or hard a ligature, for feare of paine and inflammation.

Lib. de fascijs. For *Galen* tells (as he had it from *Mantias*) that a certaine man lost his eyes by inflammation and impostumation arising, for that an Apothecarie had used too strait a ligature to his head and face; for this strait ligature so pressed the sutures, that the fuliginous vapours, which used to passe through them and the pores of the scull, were stopped from passing that way; besides, the beating of the Arteries was intercepted and hindred; by which meanes the paine and inflammation so encreased, that his eyes were rent and broke in sunder and fell forth of their orbe.

The discommodities of too strait binding of the head. Wherefore *Hippocrates* rightly commends an indifferent ligature, also hee fitly wisheth us to let the emplaisters bee soft which are applyed to the head, as also the cloathes wherewith it is bound up, to bee of soft and thinne linnen, or of Cotton, or wooll. When the patient is in dressing, if there come much matter out of the wound, you shall wish him if hee can, to lye upon the wound, and now and then by fits to strive to breathe, stopping his mouth and nose, that so the braine lifted and swollne upwards, the matter may bee the more readily cast forth; otherwise suffer him to lye so in his bed, as he shall best like of, and shal be least troublesome to him.

What cloathes we must use. You may with good successe put upon the *Crassa Meninx* oyle of Turpentine with a small quantity of *aqua vita* and a little Aloes and Saffron finely powdred, to cleanse or draw forth the *Sanies*, or matter. Or else,

How the patient must lye in his bed. *R. Mellis rosar. ʒij. farine hord. pulver. aloes, Mastich. & Ireos Florent. an. ʒʒ. aqua vita parum;* let them be incorporated together and make a deterfive medicine for the foresayd use.

Paulus lib. 6. cap. 90. Sometimes also the *Crassa Meninx* is inflamed after Trepaning, and swolne by a *Phlegmon*, that impatient of its place, it rises out of the hole made by the Trepan, and lifts its selfe much higher than the scull, whence greivous symptomes follow. Wherefore to prevent death, of which then wee ought to bee afraid, wee must enlarge the former hole with our cutting mullets, that the matter contained under the scull, by reason of whose quantity the membraine swells, may the more freely breathe and passe forth; and then we must goe about by the prescript of the Physicians to let him bleed againe, to purge and diet him. The inflammation shall bee resisted by the application of contrary remedies, as this following fomentation.

Remedies for the inflammation of the Crassa Meninx. *R. Sem. lini, althe, san. psilly, ros. rub. an. ʒj. solani, plantag. an. M. j. bulliant in aqua tepida communi, ex qua fiat fotus.* Anodyne and repelling medicines shall bee dropped into his eares; when it is exceedingly swolne, that the tumor may subside, you shall cast upon it the meale or floure of lentills, or vine leaves beaten with Goose grease. With all which remedies if the tumor doe not vanish, and withall you conjecture that there is Pus or matter contained therein, then you must open the *Dura Mater* with your incision knife, holding the point upwards and ourwards, for so the matter will be poured forth and the substance of the braine not hurt nor touched. Many other Chirurgions, and I my selfe have done this in many patients with various successe.

How we must open the Crassa Meninx when it is impostumate. For it is better in desperate causes to try a doubtfull remedy than none at all; also it oft times happens whither by the violence of the contusion and blow, or concretion or clotting of the blood which is shed, or the appulse of the cold ayre, or the rash application of medicines agreeing neither in temper nor complexion with the *Crassa Meninx*, or also by the putrifaction of the proper substance, that the *Dura Mater* it selfe becomes blacke. Of which symptome the Chirurgeon must have a great and speciall care.

The causes and remedies of the blacknesse of the Dura Mater. Therefore that thou mayst take away the blacknesse, caused by the vehemencie of the contusion, you shall put upon it oyle of egges with a little *Aqua Vita*, and

Remedies for contusion.

and a small quantity of Saffron and Orris roots in fine powder; you shall also make a fomentation of discussing and aromaticke things boiled in water and wine; and *Vigoes* Cerat formerly described shall bee applyed. But if the harme come from congealed blood, you shall withstand it with this following remedie.

R Aqua Vita ℥ij. *granor. tinctorum in tenuempulverem tritorum* ℥iij. *croci* ℥i. *Mellis rosat.* ℥ij. *sarcocol.* ℥ij. *Leviter & simul bulliant omnia, & de colatura infundatur, quousque nigrities fuerit oblitterata.* If this affect come by the touch of the ayre, it shall bee helped with this following remedie.

R Tereb. ven. ℥ij. *Mellis ros.* ℥ij. *Vuclum ovi unum, farin. hordei* ℥ij. *croci.* ℥j. *sarcocol.* ℥ij. *aq. vita* ℥ij. *Incorporentur simul, & bulliant paululum.* This remedie shall be used untill the blacknesse be taken away, and the membrane recover its pristine colour.

But if this affect proceedes from the rash use of medicines, it must bee helped by application of things contrary. For thus the offence cauted by the too long use of moyst and oyley medicines, maybe amended by using catagmaticke & cephalick powders; but the heate and biting of acride medicines, shall be mitigated by the contrary use of gentle things; for both humide and acride things somewhat long used make the part looke blacke; that truely by generating and heaping up filth, but this by the burning and hardening heate. But when such blacknesse proceedes from putrefaction, *Iohn de Vigo* commends the following remedie.

R aqua vita ℥ij. *mellis rosat.* ℥ij. But if the affect be growne so contumacious that it will not yeeld to this gentle remedie, then this following will bee convenient.

R Aq. vita ℥ij. *mellis ros.* ℥j. *pulver. Mercur.* ℥ij. *unica ebullitione bulliant simul ad usum dictum.* Or *R aqua vit.* ℥ij. *syrup. absinth & mellis rosat. an.* ℥ij. *unguenti aegyptiaci* ℥ij. *sarcocol. myrrha, aloes, an.* ℥j. *vin. albi boni & odoriferi,* ℥j. *bulliant leviter omnia simul, colentur ad usum dictum.* But if the force of the putrefaction be so stubborne, that it will not yeeld to these remedies, it will be helped with *Aegyptiacum* (made with plantaine water in steed of Vinegar) used alone by its selfe, or with the powder of Mercury alone by it selfe, or mixt with the powder of Alome. Neither must we bee afraid to use such remedies especially in this extreame disease of the *Dura Mater*; for in *Galens* opinion the *Crassa Meninx* after the scull is Trepaned delights in medicines that are acride, that is, strong and very drying, especially if it have no *Phlegmon*; and this for two reasons; the first is, for that hard and dry bodies, such as membranous bodies are, be not easily affected unlesse by strong medicines; the other is, which must be the chiefe and prime care of the Physitian, to preserve and restore the native temper of the part by things of like temper to it. But if the auditory passage not onely reaching to the hard membranes of the Braine, but also touching the Nerve which descends into it from the braine, suffer most vehement medicines, though it be placed so neere; certainly the *Crassa Meninx* will endure them farre more easily and without harme.

But if by these meanes the putrefaction be not restrained, and the tumor bee encreased so much, that the *Dura Mater* rising farre above the scull, remains unmoveable, blacke and dry, and the patients eyes looke fiery, stand forth of his head and rowle up and downe with unquietnesse and a phrensie, and these so many ill accidents be not fugitive, but constant; then know that death is at hand, both by reason of the corruption of the gangraene of a noble part, as also by extinction of the native heate.

For congealed blood.

For the hurt received by the ayre.

What medicines make the *Crassa Meninx* blacke.

Medicines as gainst that putrefaction of the *Meninx*.

Why the *Crassa Meninx* easily endures acrid medicines.

Signes of death at hand.

CHAP. XXII.

Of the cure of the Braine being shaken, or moved.

What the
concussion of
the braine is,

We have formerly declared the causes, signes and symptomes of the concussion, or shaking of the Braine, without any wound of the musculous skinne, or fracture of the bone; wherefore for the present I will treat of the cure.

Therefore in this case, for that there is feare that some vessell is broken under the scull, it is fit presently to open the cephalicke veine. And let blood be plentifully taken according to the strength of the patient, as also respectively to the disease both which is present, and like to ensue, taking the advice of a Physitian.

The opening
of the Vena
Puppis.

Then when you have shaven away the haire, you shall apply to the whole head and often renew the forementioned cataplasme, *Ex farinis, oleo rosaceo, oxymelle*, and other like cold and moist repelling medicines. But you must chew dry, and too astringent medicines must be shunned, such as are *Vnguentum de bolo* and the like; for they obstruct too vehemently, and hinder the passage forth of the vapours both by the futures and the hidden pores of the scull. Wherefore they doe not onely not hinder the inflammation, but fetch it when it is absent, or encrease it, when present. The belly shall be loosed with a glistre, and the acride vapours drawne from the head; for which purpose also it will be good, to make frictions from above downwards, to make straight ligatures on the extreame parts, to fasten large cupping-glasses with much flame to the shoulders and the originall of the spinall marrow, that so the revulsion of the blood running violently upwards to the braine, and ready to cause a phlegmon, may be the greater. The following day it will be convenient to open the *Vena Puppis*, which is seated upon the Lambdall suture, by reason of the community it hath with the veines of the braine, and shutting the mouth and nose to strive powerfully to breathe. For thus the membranes swell up, and the blood gathered betweene them and the scull is thrust forth, but not that which is shut up in the braine and membranes, of which if there be any great quantity, the case is almost desperate, unlesse nature assisted with stronger force, cast it forth turned into Pus. But also after a few dayes the *vena frontis* or forehead veine may be opened, as also the Temporall Arteries and Veins under the tongue, that the conjunct matter may be drawne forth by so many open passages.

In the meane spare the Patient must keepe a spare diet, and abstaine from wine, especially untill the fourteenth day, for that untill that time the fearefull symptomes commonly reigne. But repelling medicines must be used untill the fourteenth day be past, then we must come to discussing medicines, beginning with the more milde, such as is this following decoction.

A discussing
fomentation.

R. rad. Alth. ʒvj. ireos, cyperi, calami arom. an. ʒij. fol. salvia, Majoran, betonic. flor. chamem. melil. ros. rub. stachad. an. M. S. salis com. ʒiij. bulliant omnia simul secundum artem cum vino rub. & aqua fabrorum, fiat decoctio. Let the head be washed

A caution in
fomenting the
head.

therewith twise a day with a sponge. But yet when you doe this, see that the head be not too much heated by such a fomentation, or any such like thing, for feare of paine and inflammation.

Then you shall apply the cerate of *Vigo* which hath power to discusse indifferently, to dry, and draw forth the humors which are under the scull, and by its aromaticke force and power to confirme and strengthen the braine; it is thus described.

A description
of Vigoes
Cerate.

R. Furfuris bene trituriati ʒiij. farin. lentium ʒij. ros. myrtillor. foliorum & granorum ejus, an. ʒj. calam. aromat. ʒiij. chamamel. melil. an. M. S. nucs cupressi num. vj. olei rosacei, & chamem. an. ʒiij. cera alba ʒiij. thuris, mastichis, an. ʒiij. myrrha ʒij. In pulverem qua reatgi debent redactis, & liquefactis oleis cum cera,
omnia

omnia misceantur simul, & fiat mixtura, quæ erit inter formam emplastri & ceroti.

Vigo saith, that one of the Duke of *Urbins* Gentlemen found the virtue hereof A History. to his great good. Hee fell from his horse with his head downwards upon hard Marble, he lay as if hee had beene dead, the blood gusht out of his nose, mouth and eares, and all his face was swollen and of a livide colour; hee remained dumbe twenty dayes, taking no meat but dissolved gellies, and Chicken, and Capon broths with sugar; yet he recovered, but lost his memorie, and faultered in his speech all his life after. To which purpose is that Aphorisme of *Hippocrates*; Those which have their Braine shaken by what cause soever, must of necessity become dumbe; yea also, as *Galen* observes in his commentary, loole both their sense and motion. That Cerat is not of small efficacie, but of marvellous and admirable force, which could hinder the generating of an absesse, which was incident to the braine by reason of the fall. Aph. 58. sect. 7.

Yet there be many men so farre from yeelding to reason, that they stily denie, that any impostumation can be in the braine, and augmenting this errour with another, they deny that anywho have a portion of the braine cut off can recover, or rise againe; but the authority of ancient writers and experience doe abundantly refell the vanitie of the reasons whereon they relye. Now for the first in the opinion of *Hippocrates*; If those which have great paine in their heads have either pus, water or blood flowing from their Nose, mouth or eares, it helps their disease. That there may be an absesse in the braine.

But *Galen*, *Rhasis* and *Avicen* affirme that Sanies generated in the braine disburdens its selfe by the nose, mouth or eares; and I my selfe have observed many who had the like happen to them. Aph. 10. sect. 6.

I was told by *Prothais Coulem* Chirurgion to Monsieur de *Langey*, that he saw a certaine young man in the towne of *Mans*, who often used to ring a great bell; hee once hanging in sport upon the rope, was snatch up therewith and fell with his head full upon the pavement: he lay mute, was deprived of his senses and understanding, and was besides hard bound in his belly. Wherefore presently a feaver and delirium with other horrid symptoms assayed him, for he was not Trepaned because there appeared no signe of fracture in the skull: on the seaventh day hee fell into a great sweate with often sneesing, by the violence whereof a great quantity of matter and Pus flowed forth of his eares, mouth and nose, then hee was eased of all his symptoms, and recovered his health. Gal. lib. de inæqual. intemp. Rhaz. cap. 4. comment. Avicen. cap. de exit. fen. 3. lib. 4. cap. 20. A History.

Now for the second, *Galen* affirms that he saw a Boy in *Smirna* of *Ionia* that recovered of a great wound of the braine, but yet such an one as did not penetrate to any of the ventricles. Lib. 8. de. aff. part. 3. com. ad aph. 18. sect. 6.

But *Guido of Caulias* saith, he saw one which lived and recovered after a great portion of the braine fell out by reason of a wound received on the hind part of his head.

In the year of our Lord 1538. while I was Chirurgion to the Marshall of *Montejan* at *Turin*, I had one of his Pages in cure, who playing at quoites received a wound with a stone upon the right *Bregma* with a fracture, and so great an effraction of the bone, that the quantity of halfe a hassell Nut of the braine came forth thereat. Which I observing, presently pronounced the wound to bee deadly; a Physition which was present contradicted my opinion, affirming that substance was no portion of the braine, but a certaine fatty body. But I with reason and experience in presence of a great company of Gentlemen, convinced the pertinacie of the Man; with reason; for that fat cannot be generated under the skull, for although the parts there contained be cold, yet because they are heated by the abundance of the most hot and subtle animall spirits, and the heate of vapours rising thither from all the body, they doe not suffer fat to concreate about them. But with experience, for that in the dissecting of dead bodies, there was never any fat observed there; besides also fat will swimme on the top of water; but this substance as marrowie, cast into the water presently sunke to the bottome. Why fat cannot be generated under the skull.

Lastly, fat put to the fire becomes liquide and melts; but this substance being layd upon a hot Iron, became dry, shrunke up and contracted it selfe like a peece of leather; but dissolved not at all. Wherefore all those which were present cried out, that my judgement was right of that substance that came forth of the skull. Yet Signes of a fatty substance.

though it was cut away, Page recovered perfectly, but that he continued deafe all his life after.

CHAP. XXIII.

Of the wounds of the face.

Why we treat
in particular
of wounds of
the face.

Having treated of the wounds of the head by their causes, signes and cure, it followes that we now speake of the wounds of the face, if but for this, that when they are carelessly handled, they leave deformed scarres in the most specious and beautifull part of the body. The causes are the same which are incident to the scull, that is, externall. But this may bee added to the kindes and differences of the wounds, that the life may be out of danger though any one whole part of the face, (as the eare, eye, nose, lippe) may bee cut away by a wound, but not so in the head or scull. Wherefore beginning at the wounds of the eye browes, wee will prosecute in order the wounds of the other parts of the face.

A thing to be
observed in
wounds of the
eyebrowes.

This is chiefly to bee observed in wounds of the eye-browes, that they are oftentimes cut so overthwart, that the muscles, and fleshy pannicle which moove and lift them up, are wholly rent and torne. In which case the eye liddes cannot be opened, and the eyes remaine covered, and as it were shut up in the cases of their lids; so that even after the agglutination of the wound, if the patient would looke upon any thing, he is forc'd to hold up the eye-lids with his hand; with which infirmity I have seene many troubled, yet oft times not so much by the violence of the wound, as by the unskilfulnesse of the Chirurgion who cured them; that is, by the negligent application of boulders, an unfit ligature and more unfit suture. In this case the skillfull Chirurgion which is called to the patient shall cut off as much of the skinne and fleshy pannicle as shall serve the eyelids, that so they may by their owne strength holde and keepe open, without the helpe of the hand: then he shall sow the wound as is fit, with such a stitch as the Furriers, and Glovers use; and then he shall poure thereon some of the balsome of my description, and shall lay such a medicine to the neighbouring parts.

R Olee rosar. 3℔. album. ower. nu. ij. boli armeni, sanguinis Dracon. Mastich. an 3j. agitentur simul, fiat medicamentum. Then let the part be bound with a fitting ligature. Afterwards you shall use *Emplast. de gratia Dei, Empl. de Betonica, Diacalcitheos*, or some other like, untill the wound be cicatrized. But such like and all other wounds of the face may be easily healed, unlesse they either bee associated with some maligne symptomes, or the patient body be replete with ill humors.

Lagophthalmia
is a quite con-
trary to the
falling downe
of the eye-
lids.

There sometimes happens a quite contrary accident in wounds of the eye-browes, that is, when the eye-lids stand so up that the patient is forc'd to sleepe with his eyes open, wherefore those which are so affected are called by the Greeks *Lagophthalmi*. The cause of this affect is often internall, as a carbuncle or other kinde of abscesse, as a blow or stroake. It shall be cured by a crooked or semicircular incision made above the eye-liddes, but so that the extreames of the semicircle bend downewards, that they may be pressed downe and ioyned as much as is needefull to amend the stiffness of the eye-lidde. But you must not violate the gristle with your Instrument, for so they could no more be lifted up; the residue of the cure must bee performed as is fit.

CHAP. XXIII.

Of the wounds of the eyes.

Wounds of the eyes are made by the violence of things prickings cutting, bruising, or otherwise loosing the continuity. But the cure must alwayes be varied according to the variety of the causes and differences. The first head of the cure is, that if any strange and heterogeneous body shall be fallen into the eyes, let it be taken forth as soone as you can, lifting and turning up the eyelid with the end of a spatula. But if you cannot discern this moate or little body, then put three or foure seedes of *Clary*, or *Oculus Christi* into the pained eye. For these seedes are thought to have a faculty to cleanse the eyes and take out the moats, which are not fastned deepe in, nor doe too stubbornly adhere to the membranes. For in this case, you shall use this following instrument, for heerewith wee open the eyelids the further, putting it betweene them and the eye, and also keepe the eye stiddy by gently pressing it, that so with our mullets wee may pull out the extraneous body; this is the figure of such an Instrument.

The deliniation of a Speculum oculi, fit to dilate and hold asunder the eyelids, and keepe the eye stiddy; it is so made, that it may be dilated and contracted according to the greatnesse of the eyes.

All strange bodies taken out, let this medicine be put into the eye. Take the straines of a dozen egges, let them be beaten in a lead Mortar with a little Rose water, and so put into the eye; but let this repercussive be layd upon the eye and the neighbouring parts. *℞. albumen ovor. nu. iiii. pulver. aluminis roche combusti ʒij. sanguinis Draconis ʒj. aque rosar. & plantag. an. ʒij. agitentur simul,* make a repercussive, which you may frequently use. Or else apply cheese curds well wrung, mixed with Rosewater, the white of an Egge, and as much *acacia* as shall suffice. This which followeth doth more powerfully stay the flowing humor. *℞. gum arab. & tragac. an. ʒij. psilij. cydon. semin. portul. plant. sumach. an. ʒij. fiat mucag. cum aqua plantag. solan. & rosar. concinnetur collyrium,* of which you may drop some both within and about the eye.

A repercussive to be put into the eye.

Divers repercussives to be applied to the eye.

But note, that all such remedies must be applyed warme, both that they may the better penetrate by their moderate heate, as also for that all actually cold things are hurtfull to the eyes and sight, because they dull the sight by incrusting the visive spirits. For I have knowne many who have become dull of sight by the frequent using of medicines actually cold to the eyes.

Things actually cold are hurtfull to the eyes.

I have on the contrary seene not a few, who have recovered with the fit use of such like medicines, who have had any part of their eye (so it were not the *pupilla* or Apple of the eye) so pricked with a needle or bodkin, that much of the watrish humour ran forth thereat.

The milke of a woman which suckles a girle (for that is reputed the cooler) mitigates paine and cleanses, if it bee milked out of the Dug into the eye; to which purpose also the blood of Turtles, Pidgeons or Chickens much conduces, being dropt into the eye by opening a veine under their wings. Also this following cataplasme asswageth paine and inflammation, and hinders defluxion, being applyed to the eye

A nodyne medicines for the eyes.

and the adjacent parts. *R Carnis pomorum sub cinere calido decoctorum* ℥v. vitellos ovorum num. iij, cassia fistula recentier extracta ℥℔, mucaginis psilij, althea & cydon. an. ℥j. farin. hordei parum, incorporentur omnia simul, fiat cataplasma.

Narcotickes.

Also sheepes lungs boyled in milke and applyed warme, and changed as they grow cold, are good to aswage paine. But if the too violent heate and paine shall not yeeld to such medicines, but require more vehement, then *Foliorum Hyoscyami*, m. j. sub cineribus coquatur, atque in mortario cum mucagine seminis psilij, & cydonior, extract. in aquis solani & plantag. pistetur: then let this medicine be wrapped in a linnen cloath and applyed to the eyes and temples. The mucilages of *Psilium*, or Flea-wort, and Quince seedes extracted in a decoction of Poppy heads and mixed with a little *Opium* and Rose water, are used for the same purpose. But when there is neede of detergent and sarcoticke medicines, then *R Syrup. rosar. siccar.* ℥j. aq. fenic. & ruta an. ℥ij, aloes lota, olibani an. ℥℔. mixe them for the foresayd ule. The galls of Scates, Hares, and Partridges dissolved in eye-bright and fennell water, are fit for cleansing such wounds; as also this following *Collyrium*.

Detergent medicines.

R Aqua hordei ℥j. mellis despumati ℥iij. aloes ter lota in aqua plantaginis and sacchari cand. an. ℥j. fiat collyrium. Also this ensuing medicine is very sarcoticke.

A sarcoticke medicine for the eyes.

R mucagin. gummi olibani, arabici, tragacanth. & sarcocol. in aq. hordei extract. an. ℥iij, aloes ter lota in aq. rosarum ℥j. cerus. usta & lota, tutia prepar. an. ℥℔ fiat collyrium.

But here you must note, that the coate *Adnata* often twells so much by reason of a wound or some other injurie, and stands so forth by the falling downe of humores, accesse and mixture of flatulencies, that it hides the whole *Pupilla*, and hangs forth of the eye-lids, like as if it were an unnaturall fleshy excrescence, and it looses the native colour, and lookes very red; so that the eye can neither bee shut nor opened.

Wherewith a young Chirurgion being deceived, determined to cut away this protuberancie of the *Adnata*, as though it had beene some superfluous flesh, and then to waste it with catharteticke powders, had I not forbidden him, telling him of the certaine danger of blindness which would thereupon befall the patient. Wherefore I prescribed a fomentation of chamomile, melilote, Rose leaves, wormewood, rue, fennell, and aniseedes boyled in milke with the rootes of Orris and marigolds. Then I presently added this following fomentation, being more powerfull and drying.

A drying fomentation.

R Nucis cupressi, gallar. balaust. an. ℥j. plantag. absinth. hippuris, flo. chemam. ros. rub. an. M. B. bulliant simul cum aqua fabrorum, & fiat decoctum pro fotu cum spongia.

Besides also you may apply a cataplasme made of barley and beane flowre, the powders of Masticke, Mirrhe, and Aloes, and some of the last described decoction. The tumor beginning to decline; I drop the flowing liquor into the eye, which hath a very astringent, drying and strengthening faculty.

Roast a new layd egge in Embers untill it be hard, then pill off the shell, take forth the yolke, and in place thereof put a scruple of Roman Vitrioll in fine powder, then put it in a linnen cloath and wring it hard forth into some cleane thing, and droppe thereof for some dayes into the eye, with a little smithes water wherein Sumach and Rose leaves have beene boyled. I have found by experience the certaine force of this remedy; but if notwithstanding there be a true fleshy excrescence upon the coate *Adnata*, it may be taken away by this following powder.

A medicine to consume a fleshy excrescence without bistring.

R Ossis sepiæ & testa ovorum calcinata an. ℥j, fiat pulvis. Calcined Vitriole, burnt Aloes and the like may bee commodiously used to this purpose. Yet you must warily make use of all such things, and alwayes lay repercussives about the eye, that no harme ensue thereof.

For diverse times acride humors fall downe into the eye with such violence, that they breake the Horny coate, whereupon the humors of the eye are poured out. Remember also, that in diseales of the eyes, the Patient lye with his head somewhat high, and that he keepe shut not only the pained, but also the sound eye, because rest is alwayes necessary for the grieved part. But one eye cannot bee moved without some motion of the other by reason of the connexion they have by their opticke and moving nerves, both the *Meninges*, the *Pericranium*, Veines, and Arteries; which is the

the cause that when the one suffers, the other in some sort partakes therewith.

But if we cannot prevaile by all these formerly prescribed medicines fit to stay the defluxion, then it remaines, that wee apply a Seton to the necke; for it is a singular remedy against inveterate defluxions into the eyes. For we know by dayly experience, that many who have had their sight dulled by a long and great defluxion, so that they were almost blinde, have by little and little recovered their former splendour and sharpnesse of sight, when matter once begun to bee evacuated by the Seton.

A Seton a good remedy against inveterate defluxions into the eyes.

The truth hereof appeared in *Paul* the Italian Goldsmith, who dwelt neere the *Austine Friars*. For he having used many medicines of diverse Physicians, and Chirurgeons in vaine, when he was almost blinde, he applying a Seton, by mine advice, began by little and little to see better according to the quantity of the matter which was evacuated, untill at length he perfectly recovered his sight. But at last growing wearie of the Seton which he had worne for a yeere (although matter came dayly forth thereof) yet he would have it taken forth, and healed up; but this way of evacuation being shut up, and the humor againe beginning to flow into his eyes, so that he was in danger to become blinde, hee called me and made me againe to apply the Seton in his necke. Whereby recovering his former soundnesse and perfection of sight, he yet weares the Seton.

A History.

I also once freed by this kinde of remedy, by the appointment of the most learned Physician *Hollerius*, a certaine young man of twenty yeeres old, from the falling sicknesse, who before had many fits thereof, the Ichorous humors the feeders of this disease being by this meanes, as it is most probable, drawne away and evacuated.

A Seton good against the falling sicknesse.

Wherefore seeing a Seton is of this use, I have thought good in this place to set downe in writing and by figure, the manner of making thereof, for the behoofe of young practitioners. With the patient to sit on a low stoole, and to bend downe his head, that so the skinne and fleshy pannicle may be relaxed; then must you with your fingers plucke up and sever the skinne from the muscles, and take hold of as much hereof as you can with your pincers, not touching the muscles of the necke for feare of a convulsion and other symptomes; you shall then twitch the skinne which is held in the pincers, most hard, when you shall thrust the hot Iron through the holes made in the midst of them; that also the nerves being so twitched, the dolorifick sense may the lesse come to the part. The wound must be made or burnt in long wayes and not wharting, that so the matters may be the better evacuated by the straight fibers. But the cautery or hot Iron must have a three or else a foure-square point and that sharpe, that so it may the more easily and speedily enter. Then keeping the pincers immovable, let him draw through the passage made by the cautery a needle thred with a three or foure doubled threed of Cotton [or rather a skeane of silke] moistned in the white of an egge and oyle of Roses; then after you have applyed pledgets dipped in the same medicine, binde up the part with a convenient ligature. The day following the necke must be annointed with oyle of Roses, and the pledgets dipped in the former medicine applyed for some dayes after. But it will bee convenient to moisten the Seton with a digestive made of the yolke of an Egge and oyle of Roses, untill the ulcer cast forth much matter; then you shall annoint the Cotton thred with this following remedie. *R. terebinthina ven. ℥iij. syrupi rosar. & absinthij an. ʒss. pulveris Ireos, diacrydij, agarici trochiscati, & Rhei, an. ʒss. incorporentur omnia simul & fiat medicamentum.* Which you shall use so long, as you intend to keepe open the ulcer. For it hath a facultie to draw the humors from the face, and cleanse without biting.

The manner of making a Seton.

A figure of the Pincers, actuall Cautey and Needle used in making a Seton.

I have found not long since by experience, that the apertion made with a long thicke Triangular needle of a good length liketo a large Pack-needle, is lesse painefull, than that which is performed with the actuall cautey, which I formerly mentioned. Wherefore I would advise the young Chirurgion, that hee no more use the foresayd actuall cauterie. I have here given you the figure of the Needle.

The Figure of a Triangular Needle.

CHAP. XXV.

Of Wounds of the Cheeke.

The use of a dry suture.

Being a wound of the cheeke seemes to require a future, it must have a dry suture (as they terme it) least that the scarre should become deformed. For that deformity is very greevous to many, as to women who are highly pleased with their beauties. Therefore you shall spread two peeces of new cloath of an indifferent finenesse, and proportionable bignesse with this ensuing medicine.

How to make a dry suture.

R. pulveris mastichini, sanguinis Draconis, thuris, farina volatilis, tragacantha contusa, gypsi, picis, sarcocolla an. ʒij. picis nigra ʒiſs. albumina ovorum quæ sufficiant, fiat medicamentum. Apply the peices of cloath spread with this on each side of the wound one, some fingers breadth asunder, and let it alone till it be hard dried to the skinne. Then you shall so draw them together with your needle and thred, that the flesh by their sticking may also follow, and bee mutually adjoyned, as you may see it here exprest. The wound shall be agglutinated by this meanes, together with the use of fit medicines, pledgets, ligatures. But all the ligatures and stayes which shall be used for that purpose must be fastened to the patients night-lappe.

A Suture fit for bare-lips.

The manner thereof.

But when the wound is great and deep, and the lips thereof are much distant the one from the other, there can be no use of such a dry suture. Wherefore you must use a three or foure square needle (that so it may the more readily and easily enter into the flesh) being thred with a waxed thred; and with this you must thrust through the lips of the wound, and leave the needle sticking in the wound, and then wrappe the thred to and againe over the ends thereof eight or ten times, just after that manner which women use to fasten a needle with thred in it, upon their sleeves, or Tailors to their hatts or capps, that they may not lose them.

The

The needle thus fastened, shall bee there untill the perfect agglutination of the wound; this kind of suture is used in the wounds of the lips, as also in hare-lips, for so we commonly call lips which are cleft from the first conformation in the wombe by the error of the forming faculty. But such a suture will helpe nothing to agglutination, if there lye or remaine any skin betweene the lips of the wound; Wherefore you shall cut away whatsoever thereof shall be there, other-wise you must expect no union. Other kinde of sutures are of no great use in wounds of these parts, for out of the necessity of eating and speaking, they are in perpetuall motion; wherefore a thrid would cut the flesh; for which reason you shall take up much flesh with such Needles mentioned in this last described kinde of Suture, as this following figure shewes.

What hare-lips are

The figure of the suture fit for cloven or Hare lips, as also the delineation of the Needle about whose ends the thrid is wrapped over and under, to and againe.

A History.

To this purpose I will recite a history, to the end, that if any such thing happen to come to your hands, you may doe the like. A certaine Galcoine in the battell at Saint Laurence had his upper jaw cut overthwart even to his mouth, to the great disfiguring of his face. The wound had many wormes in it, and stanke exceedingly, because he could get no Chirurgion untill three dayes after he was hurt. Wherefore I washed it with a decoction of wormewood, Aloes and a little *Egyptiacum*, both to kill the wormes, and to fetch away all the putride matter; I discussed the tumor with a dissolving fomentation and cataplasme, I joyned together the lippes of the wound with the last described future. But I applyed this following medicine to the whole part.

A decoction
good to wash
away putres-
faction.

A small hole
remaining af-
ter the cure of
great wounds.

R. Terebinth. veneta ℥vj. gummi elemi. ℥ij. pulveris boli armeni. san. drac. Mastiches, myrrha, aloes an. ʒss. incorporentur simul. fiat medicamentum. The wound was agglutinated within a few dayes, but that there remained a certaine little whole at the joyning of the lower jaw with the upper, wherein you could scarce put the head of a pienne; out whereof neverthelesse much serous and thinne moysture flowed, especially when he either ate or spake; which I have also observed in many others. But for staying of this watrish humidity I dropped *Aqua fortis* into the bottome of the ulcer, and divers times put therein a little of the powder of burnt vitriole. Thus by Gods grace he recovered and became whole.

CHAP. XXVI.

Of the wounds of the Nose.

How many
wayes the nose
may be hurt.

He Nose many wayes suffers solution of continuity; as by a wound, fracture and contusion, and it is sometimes battered and broken on the upper part; which when it happens, you shall restore the deprest bones to their native seat and figure, with the end of a *spatula* or fir sticke wrapped about with towe, cotton or a linnen ragge. Then with pledgets dipped in an astringent medicine composed *ex albumine ovi, mastich, bolo armeno, sanguine drac. & Alumineusto*, and applyed to the side of the nose, hee shall labour to strengthen the restored bones, and then binde them with a convenient ligature, which may not presse them too much, lest the nose should become flat, as it happens to many through the unskilfulnesse of Chirurgions. Then must you put little pipes into the nose-thrills, and these not exactly round, but somewhat flat and deprest, tyed to the night-cappe on each side with a thred, least they should fall out. By the helpe of these pipes the bones of the nose will be kept in their place, and there will be passage forth for the matter, and for inspiration and expiration. But if all the nose, or some portion thereof shall bee wholly cut off, wee must not hope to restore it.

The cure of a
broken nose.

The use of
pipes in bro-
ken noses

But if the Nose bee so cut, that as yet it adheres to much of the adjacent flesh, from whence it may receive life and nourishment, then sow it up. For the lower part of the nose it may be shaken, deprest and wrested aside, seeing it is gristly; but it cannot be broken as the other which is of a bony nature.

The

The Figure of pipes to be put into the Nose-thrills.

CHAP. XXVII.

Of the Wounds of the tongue.

He tongue may bee so wounded, that either it may bee wholly cut off and deprived of some portion of the substance, or onely slit long wayes or atwhart. The losse of the substance cannot bee repaired, because every part separated and pluckt from the living body, from whence it had life, spirit and blood, presently dyes. For as the Philosophers say, *A privatione ad habitum non est regressus*. But when it is cut or slit longwayes or sidewayes, it is easily restored by suture, if so bee that the cloven part yet adhere to the living body from whence it may draw both matter and forme of life. Therefore a carefull servant shall straitly hold with a soft and cleane linnen cloth the body of the tongue, least it should slip away by reason of its slipperinesse, whilst the Chirurgeon stich it above and below; when he thinks hee hath sufficiently sowed it, let him cut off the threed as neere to the knot as he can, least being left too long it might bee tangled with the teeth as hee eates, and so cause a hurtfull laceration or tending of the sowed parts. In the meane time let the patient eate barly creames, almond milkes, Gelleyes, cullisses and broathes, and the yolkes of egges; and let him often hold in his mouth Sugar of Roses and syrupe of Quinces; for such things besides their nourishing faculty, performe the part of an agglutinating and detergent medicine.

How many wayes the continuity of the tongue may be loosed.

The cure of a cloven tongue.

I have learned these things I have here set downe, neither from my Masters whom I have heard with attention, nor by reading of bookes, but they have beene such as I have tryed with happy successe in many; as in the sonne of Monsieur de Marigny president of the Inquisition, in John Piet a Carpenter dwelling in the suburbs of Saint German.

But most apparently in a child of three yeeres old, the sonne of the great Lawyer Monsieur Conet, who fell with his chin upon a stone, and so cut off a large peece of the end of his tongue, which chanced to be betweene his teeth, it hung but at a very small fiber of flesh, so that I had very little or no hope to agglutinate and unite it, which thing almost made me to plucke it quit away; yet I changed that determination by considering the losse of the most noble action of speaking, which would thereupon enlue, and weighing the providence of nature often working wonders and such things as exceed the expectation of the physition in curing diseases.

A History.

I also thought thus with my selfe, the flesh of the tongue is soft, loose, fungous and spungie, neither is it altogether obvious to the externall injuries of the ayre; wherefore after that I had once or twice thrust through the needle and threed upwards and downwards, and for the rest ordered the child to be used and dieted after the

Nature of doth strange things in the cures of diseases.

manner I lately mentioned, he grew well within a short time, and yet remains so, speaking well and distinctly.

CHAP. XXVIII.

Of the Wounds of the Eares.

How many
wayes the unity
of eares
may be violat-
ed.
How to sew a
wounded
Eare.

He eares are sometimes wholly cut off, sometimes but in part, otherwhiles they are onely slit, so that the rent portion as yet adhearing to the rest, is joyned with it in communion of life. In this last case it is fit to use a suture; but yet so that you touch not the gristle with your needle; for thence there would be in danger of a gangrene which happens to many by foolish curing; therefore you shall take up and comprehend with your needle only the skin, and that little flesh which encompasses the gristle.

You shall performe the rest of the cure with pledgets and ligatures artificially fitted, and shall resist inflammation and other symptomes with fit medicines. But you must take speciall care that no superfluous flesh grow in the auditory passage, which may hinder the hearing; wherefore you shall keepe that passage free by stopping it with a peece of sponge. But you shall procure agglutination and consolidation of the gristly part (and therefore next to a bone most dry) with dry medicines. But those who have their eares quire cut off, can doe nothing but hide the deformity of their misse-hap with a cap, stuffed with Cotton on that side.

CHAP. XXIX.

Of the Wounds of the necke and throate.

The differ-
ences of wounds
of the necke
and throate.

He Wounds of the necke and throate are somewhiles simple, as those which onely use the continuity of the muscles; other whiles compound, such as those which have conjoynd with them a fracture of the bones, as of the *Vertebra*, or hurt of the internall and externall jugular Veines, or sleepey Arteries; sometimes the *Trachea Arteria*, or Weazon, and the *oesophagus* or gullet are wounded; sometimes wholly cut off, whence present death ensues. Wherefore let not the Chirurgion meddle with such wounds, unlesse he first foretell the danger of death, or the losse of some motion to those that are present. For it often happens that some notable nerve or tendon is violated by a wound in the necke, whence a palsey ensues, and that absolutely incurable, if the wound shall penetrate to the spinall marrow, also hurt therewith. Wounds of the gullet and Weazon are difficultly cured because they are in perpetuall motion; and chieflly of the latter by reason it is gristly and without blood. The wounds of the gullet are knowne, by spitting of blood, by the breaking forth of meate and drinke by the wound; but if the gullet be quite cut asunder, the patient cannot swallow at all. For the cut parts are both contracted in themselves, the one upwards, and the other downewards. But we know the weazon is hurt, by casting up blood at the mouth with a continuall cough, and by the comming forth of the breath or winde by the Wound. The Wounds of the jugular Veines and sleepey Arteries, if they be great, are usually deadly, because they cannot bee straitely bound up; for you cannot binde the throate hard without danger of choaking or strangling the patient. But for defect of a strait ligature in this case the fluxe of blood prooves deadly. If the recurrent Nerve of either side be cut, it makes the voyce hoarse; if cut on both sides, it takes away the use of speech, by hurting these instruments which impart motion to the muscles of the *Larynx*. For the cure if the wound be small, & not associated with the hurt of any notable vessel, nor of the Weazon and gullet, it is speedily and easily cured; and if there shall be neede you shall use a suture, then you shall put therein a sufficient quantity of Venice Turpentine mixed with bole-Armenicke; or else some of my Balsame of which this is the receipt. *R. Terebinth. veneta lb ss. gum. elemi ℥iiij. olei hypericonis ℥iiij. boli armeni, & sang. draconis an. ℥j. aqua vita ℥ij. liquefiant simul omnia lento igne, & fiat Balsamum ut artis est, addendo pulveris ireos Florent. aloes, Mastiches, myrrha, an. ℥j.* I have done wondes with this Balsame in the agglutination of simple wounds, wherein no strange body hath beene.

The palsey fol-
lowes upon
wounds of the
necke.

Signes that
the gullet
is wounded.

The wounds
of the jugular
veines and slee-
pey Arteries are
deadly by acci-
dent.

By hurting
the recurrent
Nerve the
voyce is hurt.

The descripti-
on of the Aus-
thors Balsame.

Now when you have put it in, lay upon it a plaister of *Diacalcitheos* dissolved in oyle of *Roses* and vinegar, as that which hath power to repress the flowing downe of humors, and hinder inflammation, or in steede thereof you may apply *Emp. de Diacalcitheos*.
Gratia, Dei, or Emp. de Ianna.

But if the jugular veines and sleepey Arteries bee cut, let the bleeding bee stayed, as we have shewed in a chapter, treating thereof. When the Weazon or Gullet are wounded, the Chirurghion shall sow them up as neatly as hee can; and the patient shall not endeavour to swallow any hard thing, but be content to bee fed with gelyes and brothes. When a gargarisme is needfull, this following is very good.

R. bordei M. j. florum rosar. p. j. passul. mund. jujubarum an. ʒss, glycyrrhiza ʒj. bul- liant omnia simul, addendo mellis ros. & Iulep. ros. an. ʒij. fiat gargarisma, ut artis est. A gargarisme.

With which being warme the Patient shall moisten his mouth, and throate, for it will mitigate the harshnesse of the part, aswage paine, cleanse and agglutinate, and make him breathe more freely. But that the Chirurghion may not despaire of, or leave any thing unattempted in such like wounds, I have thought good to demonstrate by some examples, how wonderfull the workes of nature are, if they be assisted by Art.

A certaine servant of Monsieur de *Champaigne*, a gentleman of *Anjou*, was wounded in the throat with a sword, whereby one of the jugular veines was cut together with his Weazon. Hee bled much and could not speake, and these symptomes remained, untill such time as the wound was sowed up, and covered with medicines. But if the medicines at any time were more liquid, hee as it were sucked them by the wound and spaces betweene the stitches, and presently put forth at his mouth that which he had sucked or drawne in. Wherefore more exactly considering with my selfe, the greatnesse of the Wound, the spermaticke, and therefore dry and bloodlesse nature unapt to agglutination, of the affected part, but chiefly of the Weazon & jugular veines, as also for that the rough Artery is obnoxious to these motions which the gullet performes in swallowing, by reason of the inner coate, which is continued to the coate of the gullet, by which meanes these parts mutually serve each other with a reciprocall motion, even as the ropes which runne to the wheele of a pulley; furthermore weighing that the Artery was necessary for the breathing, and tempering the heate of the heart, as the jugular veines served for the nourishment of the upper parts; and lastly weighing with my selfe the great quantity of blood he had lost, which is as it were the treasure of nature, I told those which were present, that death was neere and certainly at hand. And yet beyond expectation, rather by divine favour than our Art, he recovered his health.

Equally admirable is this history following. Two Englishmen walked out of the City of *Paris* for their recreation to the wood of *Vincenne*; but one of them lying in wait to rob the other of his money and a massie chaine of gold which hee wore, set upon him at unawares, cut his throate and robbed him, and so left him amongst the Vines which were in the way, supposing he had kill'd him having with his dagger cut the Weazon and gullet.

This murderer came backe to the city; the other halfe dead, crawled with much ado to a certaine Peasants house, and being dressed with such medicines as were present and at hand, he was brought to the City, and by his acquaintance committed to my cure to be cured.

I at the first, as diligently as I could, sowed up the Weazon which was cut quite asunder, and put the lips of the wound as close together as I could; I could not get hold of the gullet because it was fallen downe into the stomacke, then I bound up the wound with medicines, pledgers and fit ligatures. After he was thus drest he begun to speake, and tell the name of the villaine the author of this fact, so that hee was taken and fastened to the wheele, and having his limbes broken lost his wretched life, for the life of the innocent wounded man who dyed the fourth day after he was hurt.

The like hurt befell a certaine Germane, who laye at the house of one *Perots* in the

the streete of Nuts; he being franticke in the night cut his throate with a sword. I being called in the morning by his friends who went to see him, drest him just after the same manner as I drested the Englishman. Wherefore he presently recovering his speech, which before could not utter one sillable, freed from suspition of the crime and prison the servant, who lying in the same chamber with him, was upon suspition committed to prison, and confessing the thing as it was done, lived foure dayes after the wound, being nourished with broathes put into his fundament like clysters, and with the gratefull vapour of comfortable things, as bread newly drawne out of the Oven and soked in strong wine.

Having thus by the Art of Chirurgery made the dumbe speake for the space of foure dayes.

CHAP. XXX.

Of the Wounds of the Chest.

The differ-
ences of wounds
of the Chest.

Some wounds of the Chest are on the fore side, some behinde, some penetrate more deepe, others enter not into the capacity thereof, other some peirce even to the parts contained therein, as the *Mediastinum*, Lungs, heart, midriffe, hollow veine, and ascendent artery; Other some passe quite through the body; whereby it happens that some are deadly, some not.

The signes.

You shall thus know that the wound penetrates into the capacity of the Chest, if that when the patients mouth and nose be shut, the breath, or winde breakes through the wound with noyse, so that it may dissipate, or blow out a lighted candle being held neere it. If the patient can scarce either draw, or put forth his breath, which also is a signe that there is some blood fallen downe upon the *Diaphragma*.

Signes that
the heart is
wounded.

By these signes you may know that the heart is wounded: If a great quantity of blood gush out, if a trembling possesse all the members of the body; if the pulse bee little and faint, if the colour become pale, if a cold sweate and frequent sowning assaile him, and the extreame parts become cold, then death's at hand.

A History.

Yet when I was at *Turin* I saw a certaine Gentleman who fighting a Duell with another, received a wound under his left brest which pierced into the substance of his heart, yet for all that he stricke some blowes afterwards, and followed his flying Enemie, some two hundred paces untill hee fell downe dead upon the ground; having opened his body, I found a wound in the substance of the heart, so large as would containe ones finger; there was onely much blood poured forth upon the midriffe.

Signes that
the Lungs are
wounded.

These are the signes that the Lungs are wounded, for the blood comes foemie or frothy out of the wounds the patient is troubled with a cough, hee is also troubled with a great difficulty of breathing and a paine in his side, which hee formerly had not; he lyes most at ease when he lyes upon the wound, and sometimes it comes so to passe, that lying so he speakes more freely and easily, but turned on the contrary side, he presently cannot speake.

Signes that the
midriffe is
wounded.

When the *Diphragma* or midriffe is wounded, the party affected is troubled with a weight or heavinesse in that place, hee is taken with a *Delirium*, or raving by reason of the sympathy of the Nerves of the sixth conjugation which are spread over the midriffe; difficulty of breathing, a cough and sharpe paine trouble the patient, the Guts are drawne upwards; so that it sometimes happens by the vehemency of breathing, that the stomacke and guts are drawne through the wound into the capacity of the Chest; which thing I observed in two.

A History.

The one of these was a Mason, who was thrust through the midst of the midriffe, where it is Nervous, and dyed the third day following. I opening his lower belly, and not finding his stomacke, thought it a monstrous thing; but at length searching diligently, I found it was drawne into the Chest, though the wound which was scarce

an inch broad. But the stomacke was full of winde, but little humidity in it.

The other was called capitaine *Francis d'Aon* a Native of *Xintoigne*, who before *Roche* was shot with a musket bullet, entring by the breast-bone neere to the sword-like Gistle, and passing through the fleshy part of the midriff, went out at the space betwene the fifth and sixth bastard ribbes. The wound was healed up on the out side, yet for all that there remained a weakenesse of the stomacke, whereupon a paine of the guttes like to the colicke tooke him especially in the Evening, and on the night, for which cause he durst not sup but very sparingly. But on the eighth month after, the paine raging more violently in his belly than it was accustomed, hee dyed; though for the mitigating of the vehemency thereof *Simon Malmady* and *Anthony du Val* both learned Physitions, omitted no kinde of remedy. The body of the diseased was opened by the skillfull Chirurgeon, *James Guillemeau*, who found a great portion of the collicke gut swelled with much wind gotten into the Chest, through the wound of the *Diaphragma*, for all it was so small that you could scarce put your little finger in thereat. But now let us returne from whence we digressed.

Another History.

We understand that there is blood poured forth into the capacity of the Chest by the difficulty of breathing, the vehemency of the encreasing feaver, the stinking of the breath, the casting up of blood at the mouth, and other symptomes which usually happen to these who have putrified and clotted blood poured out of the vessels into the belly, infecting with the filthy vapour of the corrupt substance, the parts to which it shall come.

Signes that there is blood poured into the capacity of the Chest.

But also, unlesse the patient cannot lye upon his backe, he is troubled with a desire to vomite, and covets now and then to rise, whence hee often falls into a swoond, the vitall faculty which susteines the body being broken and debilitated both by reason of the wound, and concreate or clotted blood; for so putting on the quality of poyson, it greatly dissipates and dissolves the strength of the heart.

Signes that the spine is wounded.

It is a signe the spinall marrow is hurt, when a convulsion or Palsie, that is, a suddaine losse of sense and motion in the parts thereunder, an involuntary excretion of the Urine and other excrements, or a totall suppression of them, seizes upon the Patient.

When the hollow veine and great Artery are wounded, the patient will dye in a short time, by reason of the suddaine and abundant effusion of the blood and spirits, which intercepts the motion of the lungs and heart, whence the party dyes sufforaced.

CHAP. XXX.

Of the cure of the Wounds of the Chest.

WE have read in *Iohn de Vigo*, that it is disputed amongst Chirurgions concerning the consolidation of wounds of the Chest. For some thinke that such wounds must bee closed up, and cicatrized with all possible speed, least the cold ayre come to the heart, and the vitall spirits flye away and bee dissipated. Others on the contrary thinke that such wounds ought to be long kept open; and also if they be not sufficiently large of themselves, that then they must be enlarged by Chirurgery, that so the blood powred forth into the capacity of the Chest may have passage forth, which otherwise by delay would putrefie, whence wound ensue an increase of the feaver, a fistulous ulcer, and other pernicious accidents.

Vigo tract. de vuln. thorac. cap. 10.

The first opinion is grounded upon reason and truth, if so bee that there is little or no blood poured forth into the capacity of the Chest; But the latter takes place where there is much more blood contained in the empty spaces

of the Chest. Which least I may seeme rashly to determine, I thinke it not amiss to ratifie each opinion with a history thereto agreeable.

A History.

Whilest I was at *Turin*, Chirurgion to the Marshall of *Montejan*, the King of France his Generall, I had in cure a souldier of *Paris*, whose name was *L'evesque*, he served under captaine *Renonart*. He had three wounds, but one more greivous than the rest, went under the right brest, somewhat deepe into the capacity of the Chest, whence much blood was poured forth upon the midriffe, which caused such difficulty of breathing, that it even tooke away the liberty of his speech; besides, though this occasion he had a vehement feaver, coughed up blood, and a sharpe paine on the wounded side. The Chirurgion which first dressed him, had so bound up the wound with a strait and thicke suture, that nothing could flow out thereat. But I being called the day after, and weighing the present symptomes which threatned speedy death, judged that the sowing of the wound must straight be loosed; which being done, there instantly appeared a clot of blood at the orifice thereof; which made mee to cause the patient to lye halfe out of his bed, with his head downewards, and to stay his hands on a settle which was lower than the bed, and keeping himselfe in this posture, to shut his mouth and nose that so his lungs should swell, the midriffe be stretched forth, and the intercostall muscles and those of the *Abdomen* should be compressed, that the blood powred into the Chest might be evacuated by the wound; but also that this excrecion might succcede more happily, I thrust my finger somewhat deepe into the wound, that so I might open the Orifice thereof being stopped up with the congealed blood; and certainly I drew out some seaven or eight ounces of putrified and stinking blood by this meanes. When he was layd in his bed, I caused frequent injections to be made into the wound of a decoction of Barly with honey of Roses and red Sugar, which being injected I wisht him to turne first on the one, and then on the other side and then, againe to lye out of his bed as before: for thus he evacuated small, but very many clots of blood, together with the liquor lately injected; which being done, the symptomes were mitigated, and left him by little and little. The next day I made another more detergent injection, adding thereto wormewood, centaury, and Aloes; but such a bitternesse did rise up to his mouth together with a desire to cast, that he could not longer endure it. Then it came into my mind that formerly I had observed the like effect of the like remedy in the Hospirall of *Paris*, in one who had a fistulous ulcer in his Chest. Therefore when I had considered with my selfe that such bitter things may easily passe into the Lungs, and so may from thence rise into the Weazon and mouth, I determined that thence forwards I would never use such bitter things to my patients, for the use of them is much more troublesome than any way good and advantagious. But at the length this patient by this and the like meanes recovered his health beyond my expectation.

Why bitter things must not be cast in to the Chest.

Read the History of Maryllus in Galen, lib. 7. de Anatom. aduersionibus.

What harme ensues the too long use of tents.

No liniments must be used in wounds of the Chest.

But on the contrary, I was called on a time to a certaine *Germane* gentleman who was runne with a sword into the capacity of his Chest; the neighbouring Chirurgion had put a great tent into the wound at the first dressing, which I made to bee taken forth, for that I certainly understood there was no blood powred forth into the capacity of the Chest because the patient had no feaver, no weight upon the *diaphragma*, nor spitted forth any blood. Wherefore I cured him in few dayes by onely dropping in some of my balsame and laying a plaster of *Diacalcitheos* upon the wound.

The like cure I have happily performed in many others. To conclude, this I dare boldly affirme, that wounds of the Chest by the too long use of tents degenerate into *Fistula's*.

Wherefore if you at any time shall undertake the cure of wounds which penetrate into the capacity of the Chest, you shall not presently shut them up at the first dressing, but keep them open for two or three dayes; but when you shall finde that the patient is troubled with no or very little paine, and that the midriffe is pressed downe with no weight, and that he breathes freely, then let the tent be taken forth, and the wound healed up as speedily as you can by covering it onely with lint dipped in some balsame which hath a glutinative faculry, and layd somewhat broader than the wound; never apply liniments to wounds of this kinde, lest the patient by breathing draw them into the capacity of the Chest. Wherefore also you must have

a care that the tent put into those kindes of wounds may be fastened to the Pledgets, and also have somewhat a large head, lest they should be drawne as we sayd into the capacity of the Chest, for if they fall in, they will cause putrifaction and death.

Let *Emplast. Diacalcitheos* or some such like bee applied to the wound. But if, on the contrary, you know by proper, and certaine signes, that there is much blood fallen into the spaces of the Chest, then let the orifice of the wound bee kept open with larger tents, untill all the *Sanies* or bloody matter, wherein the blood hath degenerated, shall bee exhausted. But if it happen at any time, as assuredly it sometimes doth, that notwithstanding the Art and care of the Physition, the wound degenerates into a *Fistula*, then the former evill is become much worse. For *Fistula's* of the Chest, are scarce cured at any time, and that for divers causes. The first is, for that the muscles of the Chest are in perpetuall motion; Another is, because they on the contrary inside are covered onely with the membrane investing the ribbes, which is without blood. The third is, for that the wound hath no stay, by means whereof it may be compressed, sowed, and bound, whereby the lips being joyned together, the wound may at length be replenished with flesh, and cicatrized.

Wounds of the Chest easily degenerate into a *Fistula*.

But the reason why wounds of the Chest doe every day heape up and poure forth so great a quantity of matter, seemes to be their vicinity to the heart, which being the fountaine of blood, there is a perpetuall efflux thereof from thence to the part affected. For this is natures care in preserving the affected parts, that continually and abundantly without measure or meane it sends all its supplies, that is, blood and spirits, to the ayde. Ad hereto, that the affected parts by paine, heate and continuall motion of the Lungs and midriffe, draw and allure much blood to themselves. Such like blood defiled by the malignity and filth of the wound, is speedily corrupted; whence it is that from the perpetuall afflux of blood, there is a continuall efflux of matter or filth, which at the last brings a man to a consumption; because the ulcerated part like a ravenous wolfe consumes more blood by the paine, heate and motion than can be ministred thereto by the heart. Yet if there bee any hope to cure and heale the *Fistula*, it shall bee performed, (after the use of diet, phlebotomie, and according to the prescript of the Physition) by a vulnerary potion, which you shall finde described when we treat of the *Caries* or rottenesse of the bones. Wherefore you shall make frequent injections therewith into the *Fistula*, adding and mixing with it *syrupus de rosis siccis* and *mel rosa rum*. Neither doe I, if the putrefaction bee great, feare to mixe therewith *Aegyptiacum*. But you must have a care to remember and observe the quantity of the injected liquor, that you may know whether it all come forth againe after it hath performed its detergent office. For if any thereof remaine behinde in the corners and crooked passages, it hurts the part, as corrupted with the contagion thereof.

Why there flows such plenty of matter out of wounds of the Chest.

The cure of a *Fistula* in the Chest.

When *Aegyptiacum* must be put into the injections.

The forme of a Syring fit to make injection, when a great quantity of liquor is to be injected into any part.

After the injected liquor is come forth, a pipe of gold, silver or lead, shall bee put into the fistulous ulcer; and it must have many holes in it, that so the filth may passe forth at them; it must be fast tyed with strings, that it may not fall into the capacity of the Chest.

A great sponge steeped in *aqua vite* and wrung forth againe, shall bee layd hot to the end or orifice thereof, both to hinder the entrance of the ayre into the *Fistulous* ulcer, as also to draw forth the filth thereof by its gentle heate, the which thing the patients

Patient shall much further it often times both day and night hee hold his breath, stopping his mouth and nose, and lying upon the diseased side, that so the *Sanies* may bee the more forcibly evacuated; neither must wee leave putting in the pipe, before that this fistulous ulcer shall bee almost dry, that is, whole, as when it yeelds little, or no matter at all; then it must be cicatrized. But if the orifice of this fistulous ulcer being in the upper part hinder the healing thereof, then by a chirurgicall Section a passage shall be made in the bottome, as we sayd before in an *Empyema*.

The delineation of the pipes with their strings and sponges.

The reader must note that the pipes which are fit for this use, neede not have so many holes as these here exprest; but onely two or three in their ends: for the flesh growing and getting into the rest, make them that they cannot be plucked forth without much paine.

What wounds
of the Lungs
cureable.

The harme
that ensues up-
on coughing
in wounds of
the Lungs.

How *Ecleg-
ma's* must be
swallowed.

The utility of
Sugar of roses
in ulcerated
or wounded
Lungs.

A wound made in the Lungs admits cure, unless it bee very large; if it bee without inflammation; if it bee on the skirts of the Lungs, and not on their upper parts; if the patient containe himselfe from coughing much, and contentious speaking, and great breathing: for the wound is enlarged by coughing, and thence also arises inflammation; the *Pus* and *Sanies* whereof, whilst the lungs againe endeavour to expell by coughing, by which meanes they are onely able to expell that which is hurtfull and troublesome to them, the ulcer is dilated, the inflammation augmented, the Patient wastes away, and the disease becomes incurable.

There have beene many *Eclegma's* described by Physitions for to close the ulcer; which when the patient useth, he shall lye on his backe, to keepe them long in his mouth, so to relaxe the muscles of the *Larinx*; for thus the medicine will fall by little and little alongst the coates of the Weazon, for if it should fall downe in great quantity, it would be in danger to cause coughing. Cowes, Asses, or Goates milke with a little honey, least they should corrupt in the stomacke, are very fit remedies for this purpose; but womans milke exceeds the rest.

But Sugar of Roses is to be preferred before all other medicines, in the opinion of *Avicen*, for that it hath a detergent, and also an astringent and strengthening faculty, than which nothing is more to bee desired in curing of ulcers. When you shall thinke it time to agglutinate the clenfed ulcer, you must command the patient to use emplasticke, austere, and astringent medicines, such as are *Terra sigillata*, *bolus armenus*, *hypocystis*, plantaine, knot-grasse, *Sumach*, *acacia* and the like, which the patient shall use in his brothes and *Eclegma's*, mixing therewith honey of roses, which serving for a vehicle to the rest, may carry away the impacted filth which hinders agglutination. But seeing an hecticke feaver easily follows upon these kindes of wounds, and also upon the affects of the Chest and lungs, it will not be amisse to set downe somewhat concerning the cure thereof, that so the Chirurgien may know to administer some helpe to his patient, whilst a Physition is sent for, to overcome this disease with more powerfull and certaine remedies.

CHAP. XXXII.

Of the differences, causes, signes and cure of an Heeticke feaver.

Heeticke feaver is so called; either for that it is stubborne and hard to cure and loose, as things which have contracted a habite; for *Hexis* in Greeke signifies a habite; or else for that it seizes upon the solide parts of our bodies called by the Greekes *Hexeis*; both which the Latine word *Habitus* doth signifie.

The reason of the name.

There are three kinde, or rather degrees of this feaver. The first is when the heeticke heate consumes the humidity of the solide parts. The second is, when it feeds upon the fleshy substance. The third and uncureable is, when it destroyes the solide parts themselves. For thus the flame of a lampe first wastes the oyle, then the proper moysture of the weeke. Which being done there is no hope of lighting it againe what store of oyle soever you poure upon it. This feaver very seldome breeds of its selfe, but commonly followes after some other.

The difference cesterhook.

Wherefore the causes of a heeticke feaver are, sharpe and burning feavers not well cured, especially if their heate were not repressed with cooling epithemes applyed to the heart and *Hypochondria*. If cold water was not fitly drunke. It may also succcede a Diary feaver which hath bin caused and begun by some long, great and vehement grief or anger, or some too violent labour, which any of a slender and dry body hath performed in the hot sunne. It is also oftentimes caused by an ulcer or inflammation of the Lungs, an *empyema* of the Chest, by any great and long continuing *Phlegmon* of the liver, stomacke, mesentery, wombe, kidneyes, Bladder, of the guts *Jejunum* and *Colon*, and also of the other Guts, of if the *Phlegmon* succeed some long *Diarrhæa*, *Lienteria* or bloody flux; whence a consumption of the whole body, and at last a heeticke feaver, the heate becoming more acride, the moysture of the body being consumed.

The causes.

This kinde of feaver as it is most easely to bee knowne, so is it most difficult to cure; the pulse in this feaver is hard, by reason of the drynesse of the Artery which is a solide part; and it is weake by reason of the debility of the vitall faculty, the substance of the heart being assaulted. But it is little and frequent because of the distemper and heate of the heart, which for that it cannot by reason of its weakenesse cause a great pulse to coole its selfe, it labours by the oftennesse to supply that defect.

The signes.

But for the pulse, it is a proper signe of this feaver, that one or two houres after meate the pulse fees stronger than usuall; and then also there is a more acride heate over all the patients body. The heate of this flame lasts untill the nourishment bee distributed over all the patients body; in which time the drynesse of the heart in some sort tempered and recreated by the appulse of moyst nourishment, the heate increases no otherwise than lime which a little before seemed cold to the touch, but sprinkled and moystned with water growes so hot, as it smoakes and boyles up. At other times there is a perpetuall equality of heate and pulse in smallnesse, faintnesse, obscurity, frequency, and hardnesse, without any exacerbation, so that the patient cannot thinke himselfe to have a feaver, yea hee cannot complaine of any thing, hee fees no paine, which is another proper signe of an heeticke feaver.

Why in heeticke the heate is more acride after meate.

The cause that the heate doth not shew its selfe is, it doth not possesse the surface of the body, that is, the spirits and humors, but lyes as buried in the earthy grossnesse of the solide parts. Yet if you hold your hand somewhat long, you shall at last perceive the heate more acride and biting, the way being opened thereto by the skinne rarified by the gentle touch of the warme and temperate hand. Wherefore if at any time in these kinde of feavers the Patient feele any paine, and perceive himselfe troubled with an inequality and excesse of heate, it is a signe that the heeticke feaver is not simple, but conjoynd with a putride feaver, which causeth such inequality, as the heate doth more or lesse seaze upon matter subject to putrefaction; for a heeticke feaver of its selfe is void of all equality, unlesse it proceede from some externall cause,

The signes of a heeticke joyned with a putride feaver.

The cure,

as from meate; Certainly if an Hippocraticque face may be found in any disease, it may in this, by reason of the colliquation, or wasting away the triple substance. In the cure of this disease, you must diligently observe with what affects it is entangled, and whence it was caused. Wherefore first you must know whether this feaver be a disease; or else a symptome. For if it be symptomaticall it cannot be cured;

A symptomaticall hecticke.

as long as the disease the cause thereof, remaines uncured; as if an ulcer of the guts occasioned by a bloody fluxe shall have caused it, or else a fistulous ulcer in the Chest caused by some wound received on that part, it will never admit of cure, unlesse first the fistulous or dysenterick ulcer shall be cured; because the disease feedes the symptomes, as the cause the effect. But if it be a simple and essentiall hecticke feaver, for that it hath its essence consisting in an hot and dry distemper, which is not fixed in the humors, but in the solide parts, all the counsell of the Physicion must be to renew the body, but not to purge it; for onely the humors require purging, and not the defaults of the solide parts. Therefore the solide parts must bee refrigerated and humected; which wee may doe by medicines taken inwardly and applyed outwardly.

An essentiall hecticke.

Things to bee taken inwardly.

The things which may with good successe bee taken inwardly into the body for this purpose, are medicinall nourishments. For hence we shall finde more certaine and manifest good, than from altering medicines, that is, wholly refrigerating and humecting without any manner of nourishment.

The benefit of medicinall nourishments.

For by reason of that portion fit for nutriment which is therewith mixed they are drawne and carried more powerfully to the parts, and also converted into their substance: whereby it comes to passe that they doe not humect and coole them lightly and superficially, like the medicines which have onely power to alter and change the body, but they carry their qualities more thoroughly even into the innermost substance.

Of these things some are herbes, as violets, purslaine, buglosse, endive, duck-s-meat, or water lentill, mallowes, especially when the belly shall be bound. Some are fruits, as gourds, cowcumbers, apples, prunes, raisons, sweete almonds, and fresh or new pine-apple kernells. In the number of feedes are the foure greater and lesser cold feedes, and these new, for their native humidity, the feedes of poppyes, berberries, quinces. The floures of buglosse, violets, water lillies, are also convenient; of all these things let broth be made with a chicken, to bee taken in the morning for eight or nine dayes, after the first concoction.

The choyce of meates.

For meates; in the beginning of the disease, when the faculties are not too much debilitated, hee shall use such as nourish much and long, though of hard digestion; such as the extreame parts of beasts, as the feete of Calves, Hoggs feete not salted, the flesh of a Tortois, which hath lived so long in a garden, as may suffice to digest the excrementitious humidity; the flesh of white Snailles, and such as have beene gathered in a vineyard, of frogs, river Crabs, Eccles taken in cleere waters and; wel-cooked, hard egges eaten with the juice of Sorrell without spices; Whittings and stockfish. For al such things because they have a tough and glutinous juice, are easily put & glutinated to the parts of our body, neither are they so easily dissipated by the feaverish heat. But when the patient languisheth of a long hectick, he must feede upon meates of easy digestion, and these boyled rather than roasted; for boyled meates humect more, and roasted more easily turne into choler. Wherefore hee may use to eate Veale, Kid, Capon, Pullet, boyled with refrigerating and humecting hearbes; hee may also use Barly creames, Almond milkes, as also bread crummed and moystened with rose water and boyled in a decoction of the foure cold feedes with sugar of roses; for such a Panada cooles the liver, and the habite of the whole body, and nourisheth withall.

The Testicles, wings, and livers of young cockes, as also figges and raisons. But if the patient at length begin to loathe and grow weary of boyled meates, then let him use roast, but so that he cut away the burnt and dried part thereof, and feed onely on the inner part thereof, and that moystned in rose water, the juice of Citrons, Oranges or Pomegranats. Let him abstaine from salt and dry fishes, and chuse such fishes as live in stony waters, for the exercise they are forc'd to undergoe in shunning the rocks

rockes beaten upon by the waves. Asses milke newly milked and seasoned with a little salt, sugar, honey, or fennell, that it may not corrupt, nor grow sowre in the stomacke; or womans milke sucked from the dug by the patient, to the quantity of halfe a pint is much commended; verily womans milke is the more wholsome, as that which is more sweet and familiar to our substance, if so be that the nurse be of a good temper and habite of body. For so it is very good against the gnawings of the stomacke, and ulcers of the Lungs, from whence a Consumption often proceeds. Let your milch Ass be fed with barley, oates, oake leaves; but if the patient chance to bee troubled with the fluxe of the belly, you shall make the milke somewhat astringent, by gently boyling it, and quenching therein pebble stones heated red hot. But for that all natures cannot away with Asses milke, such shall abstaine from it, as it makes to have acrid belchings, difficulty of breathing, a heate and rumbling in the *Hypochondria*, and paine of the head. Let the patient temper his wine with a little of the waters of Lettuce, purslane and water-lillies, but with much buglosse water, both for that it moistens very much, as also for that it hath a specificke power to recreate the heart, whose solide substance in this kinde of disease is greivously afflicted. And thus much of things to be taken inwardly.

How Asses milke must be used in a nettick.

Womans milke more wholsome than Asses.

These things which are to be outwardly applyed, are inunctions, bathes, epithemes, clysters. Inunctions are divers, according to the various indication of the parts where to they are applyed. For *Galen* annoints all the spine with cooling & moderate astringent things, as which may suffice to strengthen the parts, and hinder their wasting, and not let the transpiration; for if it should bee letted, the heate would become more acide, by suppressing the vapours. Oyle of roses, water lillies, Quinces, the mucilages of Gumme tragacanth and arabicke extracted in water of nightshade, with some small quantity of camphire, and a little waxe if neede require; but on the contrary, the parts of the breast must be annoynted with refrigerating and relaxing things; by refrigerating I meane things which moderately coole, for cold is hurtfull to the breast. But astringent things would hinder the motion of the muscles of the chest, and cause a difficulty of breathing. Such inunctions may be made of oyle of Violets, willowes, of the seeds of lettuce, poppyes, water-lillies, mixing with them the oyle of sweete almonds to temper the astringion which they may have by their coldnesse. But you must have great care that the Apothecarie for covetousnesse in steed of these oyles newly made give you not old, rancide and salted oyles, for so in steed of refrigerating, you shall heate the part; for wine, honey and oyle acquire more heate by age; in defect of convenient oyles, we may use butter well washed in violet and nightshade water. The use of such inunctions, is to coole, humect and comfort the parts whereto they are used; they must be used evening and morning, chiefly after a bath.

Things to be outwardly applyed.

A caution in the choyse of Oyles.

Now for Bathes, we prescribe them either onely to moisten, and then plaine warme water wherein the flowres of Violets and water lillyes, willow leaves and barley have beene boyled, will be sufficient; or else not onely to moisten, but also to acquire them a fairer and fuller habite, and then you may adde to your bath the decoction of a sheepes head and Gather, with some butter. But the patient shall not enter into the bath fasting, but after the first concoction of the stomach, that so the nourishment may be drawne by the warmenesse of the bath into the whole habite of the body, for otherwise he which is sicke of a consumption and shall enter the bath with his stomacke empty, shall suffer a greater dissipation of the triple substance, by the heate of the bath, than his strength is well able to endure. Wherefore it is fit thus to prepare the body, before you put it into the bath. The day before in the morning let him take an emollient-clyster, to evacuate the excrements baked in the guts by the heeticke drynesse; then let him eate to his dinner some solide meats about nine of the clocke; and let him about foure of the clocke eate somewhat sparingly, meates of easie digestion to his supper. A little after midnight let him sup of some chicken broth or barley creame, or else two reare egges tempered with some rose water and sugar of roses in steed of salt. Some 4. or 5. hours after, let him enter into the bath, these things which I have set downe, being observed. When he comes out of the bath, let him be dried and gently rubbed, with soft linnen cloathes, and annointed as I former-

The differences of bathes.

Why the patients must not enter the Bath fasting.

How to prepare the body for the Bath.

Things
strengthening
the ventricles.

Epithemes.

ly prescribed, then let him sleepe if he can for two or three houres in his bed: when he wakes let him take some Prisan, or some such like thing, and then repeate his bath after the foresayd manner. He shall use this bath thrice in ten dayes; But if the patient be subject to crudities of the stomacke, so that hee cannot sit in the bath without feare of fowning and such symptomes, his stomacke must be strengthened with oyle of Quinces, Wormewood and Mastich, or else with a crust of bread tosted, and steeped in muskedine, and strewed over with the powders of Roses, Sanders, and so layd to the stomacke, or behinde neare to the thirteenth *vertebra* of the backe, under which place, Anatomie teaches, that the mouth of the stomacke lyes. Epithemes shall be applyed to the liver and heart, to temper the too acride heate of these parts, and correct the immoderate drynesse by their moderate humidity.

What a fluxe
happening in
a heeticke feaver
indicates.

How children
be cured.

Now they shall be made of refrigerating and humecting things, but chiefly humecting; for too great coldnesse would hinder the penetration of the humidity into the part lying within. The waters of Buglosse, and Violets, of each a quarterne with a little white wine is convenient for this purpose. But that which is made of French barley, the seedes of gourds, pompions, or Cowcubers of each three drams in the decoction, and mixed with much tempering with oyle of Violets, or of sweete almonds, is most excellent of all other. Let clothes be dipped and steeped in such epithemes, and layd upon the part, and renewed as oft as they become hot by the heate of the part. And because in heeticke bodies, by reason of the weakenesse of the digestive facultie, many excrements are usually heaped up, and dried in the guts, it will be convenient, all the time of the disease to use frequently glisters made of the decoction of cooling and humecting hearbes, flowres, and seedes wherein you shall dissolve *Cassia* with sugar and oyle of Violets, or water-lillies. But because there often happen very dangerous fluxes in a confirmed heeticke feaver, which shew the decay of all the faculties of the body, and wasting of the corporall substance, you shall resist them with refrigerating and assisting medicines; and meates of grosser nourishment, as Rice, and Cicers, and application of astringent and strengthening remedies; and using the decoction of Oates or parched barley for drinke. Let the patient be kept quiet and sleeping as much as may be, especially if he be a child.

For this feaver frequently invades children by anger, great and long feare, or the too hot milke of the nurse, overheating in the Sunne, the use of wine and other such like causes; they shall be kept in a hot and moystayre, have another Nurse, and be anoynted with oyle of violets; to conclude, you shall apply medicines which are contrary to the morbificke cause.

THE NEW EDITION OF THE
OF THE GREENE AND BLOODY

CHAP. XXXIII.

Of the wounds of the Epigastrium and of the whole lower belly.

Their differences.

Signes of a
wounded
liver.

Signes that the
stomacke and
smaller guts
are wounded.

Signes to
know when
the greater
guts are
wounded.

He wounds of the lower belly are sometimes before, sometimes behind, some onely touch the surface thereof, others enter in; some passe quite through the body, so that they often leave the weapon therein, some happen without hurting the contained parts; others grievously offend these parts, the liver, spleene, stomacke, guts, kidneyes, wombe, bladder, ureters, and great vessels, so that oft times a great portion of the Kall falls forth. We know the Liver is wounded, when a great quantity of blood comes forth of the wound, when a pricking paine reaches even to the swordlike gristle, to which the Liver adheares. Oft times more choler is cast up by vomit, and the patient lyes on his belly with more ease, and content.

When the stomacke or any of the small guts are wounded, the meate and drinke break out at the wound, the *ilia* or flankes swell and become hard, the hicket troubles the patient, and oft times he casts up more choler, and greivous paine wrings his belly, and hee is taken with cold sweates, and his extreme parts waxe cold.

If any of the greater guts shall bee hurt, the excrements come forth at the wound:

When

2:4:1

A History.

Another His-
tory.

The first cogitation in curing of these wounds ought to be whether they pierce into the capacitie of the Belly; for those which passe no further than to the *Peritoneum* shall be cured like simple wounds which only require union. But those which enter into the capacity must be cured after another manner. For oft times the Kall or Guts, or both fall forth

The cure of
a wounded
Gut;

... Mm ... mäßig,

Mastic, Myrrhe, Aloes and Bole. Being sowed up, it must not bee put up boystrously together and at once into its place, but by little and little, the Patient lying on the side opposite to the wound. As for example, the right side of the Guts being wounded and falling out by the wound, the Patient shall lye on his left side, for the more easy restoring of the fallne downe Gut, and so on the contrary. If the lower part of the Guts being wounded slide through the wound, then the Patient shall lye with his head low downe, and his buttocks raised up by putting a pillow under them; If the upper part be hurt, then must he lye quite contrary, that the Guts falling downewards by such a site, may give way to these which are fallne out through the wound. But often in this case, the Guts having taken cold by the encompassing aire, swell up & are distended with winde, the which you must discusse before you put them into their place, with a fomentation of the decoction of camomill, melilote, aniseeds and fennell applyed with a sponge, or contained in a bladder; or else with chickens, or whelpes cut alive in the midst and layd upon the swelling; for thus they doe not onely discusse the flatulency, but also comfort the afflicted part. But if the inflation cannot thus be discussed, the wound shall be dilated, that so the Guts may returne the more freely to their place.

The cure
when the Kall
falls out.

Hip. Aph. 8.
sect. 5.

Lib. 6. Meth.

Lib. 6. Meth.
cap. 4.

The cure of
the wounded
fat.

If the Kall shall fall out, it must be speedily restored to its place, for it is very subject to putrifie; for the fat, whereof for the most part it consists, being exposed to the aire, easily looses its native heate, which is small and weake, whence a mortification ensues. Hence is that of *Hippocrates*; If the Kall fall out, it necessarily putrifies. The Chirurgeon shall know whether it putrifie, or not, by the blacknesse and the coldnesse you may perceiv by touching it; neither must you when it putrifies presently restore it to its place, for so the contagion of the putrifaction would spread to the rest of the parts: but what soever thereof is putrefied shall be twiched and bound hard with a string and so cut off, and the rest restored to his proper place: but its good after cutting of it away to leave the string still hanging thereat, that so you may plucke and draw forth whatsoever thereof may by being too straight bound fall away into the capacity of the belly. Some thinke it to be better to let the Kall thus bound to hang forth untill that portion thereof which is putrified fall away of it selfe, and not to cut it off. But they are much deceived, for it hanging thus would not cover the guts, which is the proper place. The Guts and Kall being put up, if the wound be great and worth speaking of, it must be sowed with that suture which is termed *Gastroraphia*; but this kind of suture is thus made. The needle at the first putting in must onely take hold of the *peritoneum*, & then on the opposite side onely of the flesh, letting the *peritoneum* alone, and so goe along putting the needle from without inwards, and from within outwards, but so that you onely take the musculous flesh and skinne over it, and then onely the *peritoneum*, untill you have sowed up all the wound. Hec which doth otherwise shall undergoc this danger, that whereas the coate *peritoneum* is of it selfe without blood, it being devided, or wounded cannot of it selfe be united to it selfe, therefore it requires an intercourse of flesh: otherwise unlesse it be thus united by the benefit of the flesh intermixed therewith, there would remaine an incurable Tumour after the wound is cicatrized on the outside. But that which wee sayd before according to *Galens* minde, that all the wounds must be sowed, it is not so to be taken as if that the wound must be sowed up to the very end; for in the lower part of the wound there must be left a certaine small vent by which the quittance may passe forth, which being wholly clenled and exhausted, the wound must be quite healed up. But the wounds which shall penetrate into the substance of the liver, spleene, ventricles, and other bowells, the Chirurgeon shall not suffer them to be without medicines as if they were desperate, but here shall spare neither labour nor care to dresse them diligently. For doubtfull hope is better than certaine despaire. The bladder, wombe, and right gut being wounded, detergent and agglutinative injections shall be put up by their proper passages. I have read nothing as yet in any author of the wounds of the Fat, for all of them referre the cure thereof to the wounds of the Muscles. Yet I will say this by the way, that wounds of the fat how deepe soever they be, if they be onely simple, may be dressed without putting in of any Tent, but onely dropping in some of my balsame, and then laying upon it a plaister of *Gratia Dei*, or some such like, for so they will heale in a short time.

CHAP. XXXV.

Of the wounds of the Groines, Yard and Testicles.

When the Groines and neighbouring parts are wounded, we must first consider whether they pierce to within: and if they doe penetrate, to what inward parts the come, whether to the bladder, the wombe, or right gut: for these parts are such neare neighbours that oft times they are all wounded with one blow. But for the wounds of the Testicles, and genitall parts, because they are necessary instruments for the preserving the *species* by generation, or a succession of individualls, and to keepe all things quiet at home, therefore the Chirurgion ought to be very diligent and carefull for their preservation. Wherefore if they should chance at any time to be wounded, they shall be dressed as we have formerly delivered, the medicines being varied according to the state of the wound, and the appearing and happening symptomes; for it would be a thing of immense labour to handle all things in particular.

CHAP. XXXVI.

Of the Wounds of the Thighes and Legges.

Wounds which have beene received on the inside of the Thighes, have often caused suddaine death, if they have come to the veine *Saphena*, or the great Artery, or the Nerves the associates of these vessels. But when they are simple, there is nothing which may alter the usual manner of cure. Yet the patient must be carefull to lye in his bed: for the vulgar Italian proverb is true. *La mano al petto, la gamba al letto*, [that is, the hand on the breast, and the legge on the bed] But when they penetrate more deeply into the substance of the part, they bring horrid and fearefull symptomes, as an inflammation, an absesse, from whence oft times such abundance of matter issues forth, that the Patient falls into an *Atrophia* and consumption. Wherefore such wounds and ulcers require a carefull and industrious Chirurgion, who may fitly make incisions necessary for the corrupt parts, and callosity of the fistulous ulcer. Some Chirurgions have beene so bold as to sowe together the end of the Tendons of the Ham, and of other joynts, when they have beene quite cut asunder. But I durst never attempt it for feare of paine, convulsions and the like horrid symptomes. For the wounds of that large Tendon which is composed in the calfe of the Legge by the concurrence of three muscles, and goes to the heele, I have observed that when it hath beene cut with a sword, that the wounds have beene long and hard to cure; and besides when at the last they have beene healed, as soone as the Patient hath got out of his bed, and endeavoured to goe, they have growne ill and broke open againe. Wherefore in such like wounds let the Patient have a care that he begin not to goe, or too boldly to use his hurt leg before it be perfectly cicatrized and the scarre growne hard. Therefore that the patient may be in more safety, I judge it altogether necessary, that he use to goe with Crutches, for a good while after the wound is perfectly healed up.

Why wounds of the inside of the Thigh are oft times deadly.

The large Tendon of the heele hard to consolidate.

CHAP. XXXVII.

Of the wounds of the Nerves, and nervous parts.

He continuity of the nervous parts is divers wayes loosed by the violent incursion of externall things; as by things which contuse, batter and grinde in sunder, as by the blow of a stone, cudgell, hammer, lance, bullet out of a gun, or crooked bow; by the biting of greater teeth; or the pricking of some sharpe thing, as a needle, bodkin, penknife, arrow, splinter; or the puncture of some venomous thing, as of a Sea Dragon; or the edge of some cutting thing, as a sword or Rapier; or of stretching things which violently teare asunder the nervous bodies. Hence therefore it is, that of such wounds some are simple, others compound, and the compound, some more compound than other. For of these some are su-

Differences drawne from things wounding.

tomes.

Why a punc-
ture of a nerve
is deadly.

perficiary and short, others deepe and long; some runne alongst the nervous body, others runne broadwayes; some cut the part quite asunder, others onely a portion thereof. The symptoms which follow upon such wounds are, vehement paine, and defluxion, inflammation, abscesse, feaver, *delirium*, fawning, convulsion, gangrene, sphacell; whence often death ensues by reason of that sympathy, which all the nervous parts have with the braine. Amongst all the wounds of the nervous parts, there is none more to be feared than a puncture, or pricke, nor any which causeth more cruell and dangerous symptoms. For by reason of the straitnesse of the wound, medicines can neyther be put in, nor the sanious matter passe forth: now the sanious matter by long stay acquires virulencie, whereby the nervous parts are tainted and swollne, suffer paine, inflammation, convulsions and infinite other symptoms; of these the wounds are most dangerous, by which the nervous and membranous bodies are but halfe cut asunder. For the portion whereof which remaines whole, by its drawing and contracting its selfe towards the originall, causeth great paine and convulsion by sympathy. The truth hereof is evident in wounds of the head, as when the *pericranium* is halfe cut, or when it is cut to apply a Trepan. For the cutting thereof infers farre greater paine, than when it is cut quite asunder. Wherefore it is safer, to have the nervous body cut quite off, for so it hath no community, nor consent with the upper parts, neither doth it labour, or strive to resist the contraction of its selfe; now this contrariety, and as it were fight, is the cause of paine; yet there arises another misery from such a wound, for the part whereinto the nerve which is thus cut insunder passes, thence forwards looseth its action.

CHAP. XXXVIII.

Of the cure of wounds of the nervous parts.

A wound of
the nervous
parts indicates
contrary to
the generall
cure of
wounds.

A Historic.

IT is the ancient doctrine of the ancient Physicians, that the wounds of the nervous parts should not presently be agglutinated (which notwithstanding the generall and first indication usually taken from the solution of continuity requires) but rather, chiefly if they be too strait, that the punctures should be dilated, by cutting the parts which are above them, and let them be kept long open that the filth may passe freely forth and the medicine enter well in. Yet I in many cures have not followed this counsell, but rather that which the common indication requires.

That cure is in fresh memory which I performed upon Monsieur le Cœq, a Procter of the spirituall court, who dwelt in our Ladies streete; he gathering and binding up some loose papers, run a penknife which was hid amongst them, through his hand. Also one of his neighbours who went to spit a piece of beefe, thrust the spit through the midst of his hand. But I presently agglutinated both their wounds, without any danger, dropping presently in at the first dressing a little of my balsame warme, & putting about it a repelling & astringent medicine, & by this meanes they were both of them healed in a short time, no symptome thereupon happening. Yet I would not have the young Chirurgion to run this hazard, for first he must be well practised and accustomed to know the tempers and haits of men; for this manner of curing would not doe well in a plethoricke body, or in a body replete with ill humours, or endued with exquisite sense. Therefore in such a case it will be safer to follow the course here set downe. For wounds of the nerves doe not onely differ from other wounds, but also among themselves in manner of curing. For although all medicines which draw from farre, and waste sanious humors, may be reputed good for the wounds of the nerves; yet those which must be applyed to punctures and to those nerves which are not wholly laid open, ought to be far more powerfull, sharpe and drying, yet so that they be not without biting, that so penetrating more deepe they may draw forth the matter, or else consume and discusse that which eyther lies about the nerves, or moistens their substance. On the contrary when the sinewes are bared from flesh and the adjoyning particles, they stand in neede but of medicines, which may onely dry. Here you may furnish your selves with sufficient store of medicins good for the nerves howsoever pricked. As *R. Terebinth. ven. & olei veteris an ʒj. aqua vita parum.* Or *R. olei Terebinth. ʒj. aqua vita ʒj. euphorb. ʒss.* Or *R. radices Draconis, Brionia, valeriana, & gentiana exsiccatas, & in pulverem redactas, misce cum decocto centaury,*

Medecines fit
for wounds
of the nerves.

aut oleo, aut exungia veteri; drop hereof warme into the wound as much as shall suffice. Or else put some Hogges, Goose, Capons, or Beares grease, old oyle, oyle of Lillyes or the like, to *Galbanum*, pure Rozin, *opopanax* dissolved in *aqua vite* and strong vinegar. Or *R. olei hypericonis, sambuci, & de euphorbia an. ʒij. sulphuris vivi subtiliter pulverisati ʒʒ gummi ammoniaci, bdellij, an. ʒij. aceti boni ʒij. vermium terrest. preparat. ʒij. bullians omnia simul ad consumptionem aceti.* Let as much hereof as shall suffice be dropped into the wound; then apply this following cerate, which drawes very powerfully. *R. olei supra scripti ʒj. terebinth. venet. ʒʒ. diachylonis albi cum gummi, ʒx. ammoniac. bdellij in aceto dissolutorum an. ʒij. resin pinz. gum. elemi. picis navalis an. ʒv. cera quod sufficit, fiat ceratum satis molle.* We must use somewhiles one, somewhiles another of these medicines in punctures of the Nerves with choise and judgement, according to their conditions, manner, depth, and the temperaments and habit of the wounded bodies. But if the paine yeeld not to such remedies, but rather increase, with the inflammation of the affected part, a swelling of the lips of the wound, and sweating forth of a serous, thinne and virulent matter or filth, then you shall poure into it sealding oyle, and shall touch three or foure times not onely the surface of the wound but the bottome thereof with a ragge dipped therein and tyed to the end of a *spatula*. For this will take away the sense from the Nerve, Tendon, or Membrane, like as if they were burnt with a cautery, and so the paine will be eased. So in the most grievous paines of rotten teeth, the thrusting of an hot iron into their roots, or stopping them with cotten dipped in oyle of Vitrioll, or *aqua vite*, gives most certaine ease; for by burning the Nerve which is inserted into their roots, the sense and so consequently the paine is taken away. So also in malignant, gnawing, eating, and spreading ulcers, which are alwayes associated with much paine, the paine ceases by applying an Escharoticke, as the pouders of Alum, or Mercury, or *egyptiacum* made somewhat more strong than usuall. That the yong Chirurgion may be more ready for this practise and the use of the former remedies, I have thought good to insert the following History both for the lateness of the thing and the pleasing memory of the most laudible Prince.

what wounds
of the Nerves
must be burnt.

A certaine
Anodyne in
paine of the
teeth.

Why Escharo-
ticks must be
used to spread-
ding ulcers.

Charles the ninth the French King being sicke of a feaver, Monsieur Chapellan and Castellan his Physicians thought it fit hee should be let blood; for the performance whereof, there was called a Chirurgion wondrous famous for that businesse; but when as he by chance had pricked a nerve in stead of a veine, the King cryed out, that he felt a mighty paine in that place. Then I bid, that the ligature should straightwayes be loosed, otherwise the arme would presently be much swelled. But he going slowly about it, behold the arme begun to swell with such contraction, that he could not bend it, nor put it forth, and cruell paine molested not onely the pricked particle, but all the whole member besids. I forthwith laid upon the wound a plaister of *Basilicō*, to hinder the agglutination thereof, & then I wrapped all the arme in a double linnen cloth dipped in oxycrate, putting upon it an expulsive ligature, which beginning at the wrist & ending at the top of the shoulder, might keepe the blood and spirits from feare of defluxion and inflammation. This being thus performed, we went aside to consult what was necessary to be done, both to allwage the paine, as also to divert the other symptoms, which usually happen upon punctures of the nerves. I being desired, thus delivered my opinion, that in my minde, there were nothing better, than presently to drop into the wound some oyle of Turpentine warmed and mixed with a little *aqua vite*. And then all the arme should be covered with a plaister of *Diacalcitheos* dissolved in vinegar and oyle of Roses, bound over and besides with the expulsive ligature, which we formerly mentioned. For the oyle and *aqua vite* have a faculty to penetrate into the bottome of the wound, & to exhaust and dry up, the serous and virulent humour, which sweats from the substance of the pricked nerve; and also to mitigate the paine by its actuall heate. Furthermore the emplaster *Diacalcitheos* hath a faculty to dissolve the humour which hath already fallen downe into the arme, and to hinder the entrance and defluxion of any new matter. And the ligature is such as by its moderate striction would serve to strengthen the muscles, and to presse out and repell the humours which were fallen downe into the upper part, and to prohibite that which is ready to fall downe. Mine advice being approved of the Physicians

A famous his-
torie.

both in word and deede, the paine was mitigated. But the humour stayed in the part, for the dissolving and drying whereof, this following remedy was used.

A dissolving
and drying ca-
tastrophe.

R. far. hordei & orobi, an. ʒij. flor. chamam. & melilot. an. p. ij. butyr. recentis sine sale ʒjss. lixivij barbitonferis quod sufficit, fiat cataplasma ad formam pulvis. By these remedies the King at the last after three months space was perfectly healed, so that there remained no signe of the depraved action in the part. But if at any time there shall be so great contumacie, that it will not yeeld to these meanes, but that there is imminent danger of a convulsion; it will bee better to cut it in sunder whether Nerve, Tendon or Membrane, than to expose the patient to the danger of a deadly convulsion; for thus indeede the peculiar action of that part will be lost, but the whole body preserved thereby; for so we had determined by common consent, that if the paine which afflicted the King would not yeeld to the prescribed remedies, eyther to poure in scalding oyle, or else to cut the sinew quite asunder.

A Historie.

For the late and sad memory of Mistris *Courtin* dwelling in the streere of the holy-Crosse was in our mindes, who of a veine not well opened in her arme fell into a Gangraene and totall mortification of that whole part, of which shee died, because shee was not dressed with the formerly mentioned medicines. Yet wee must abstaine from these too powerfull remedies, when the pricked nerve shall lye bare, for else the paine would be encreased, and more grievous symptomes follow. Wherefore as I have formerly wished, more milde medicines must be applyed, which may dry up the serous humour without biting or acrimonye, as *R. cerebinth. venet. in aq. ros. lota ʒij. boli armen. subtiliter pulverisati, ʒij. incorporantur simul.* Our Ballame also is excellent in this case, and this of *Vigoes* which followes.

An anodyne
and Sarcotick
Ballame.

R. olei. rosar. omphacini ʒjss. olei de terebinth. ʒij. succi plantag. ʒss. semin. hypericonis aliquantulu contriti. m. s. tutia prepar. ʒij. calcis decies lota cum aqua plantagin. ʒij. antimony ʒi. sevi hircini, & vitulini, an ʒv. vermium terrestrium cum vino lotorum ʒjss. bulliant omnia simul dempta tutia in cyatho decoctionis hordei, ad consumptionem aquae & vini, colentur, rursumq; igni admoveantur, addendo tutiam, & fiat linimentum cum cera alba, & ʒss. croci. This liniment asswages paines, and covers the bared nerves with flesh. This cure of punctured nerves, may with choise and judgement and observing the proportion of the parts be transferred to the pricked Tendons and membranes. But take this as a generall and common rule, that all nervous bodies howsoever hurt, are to bee comforted by anointing them with hot oyles, such as the oiles of Bayes, Lillies, of Wormes, Sage, or some other such like remedy being applyed to their originalls and more notable passages; as to the originall of the spinall marrow, the armpits and groines. Neither doe I thinke it fit in this place to omit an affect which sometimes happens to the large Tendon of the heele, of which we formerly made mention. For it oft times is rent or torne by a small occasion without any signe of injury or solution of continuity apparent on the outside as by a little jumpe, the slipping aside of the foote, the too nimble getting on horseback, or the slipping of the foote out of the stirrop in mounting into the sadlle. When this chance happens it will give a cracke like a Coachmans whip; above the heele, where the tendon is broken, the depressed cavity may be felt with your finger, there is great paine in the part, & the parry is not able to goe. This mischance may be amended by long lying and resting in bed, and repelling medicines applyed to the part affected in the beginning of the disease, for feare of more grievous symptomes; & then applying the Blacke plaister, or *Diascaltitheatos* or some other such, as neede shall require; neither must we hereupon promise to our selves or the patient certaine or absolute health. But on the contrary at the beginning of the disease we must foretell, that it wil never be so cured but that some reliques may remaine, as the depression of the part affected and depravation of the action and going; for the ends of this broken or relaxed Tendon by reason of its thickenesse and contumacie cannot easily be adjoynded, nor being adjoynded, united.

A generall
rule for all
wounds of
all Nervous
parts.

CHAP. XXXIX.

Of the wounds of the joynts.

BEcause the wounds of the joynts have something proper and peculiar to themselves, besides the common nature of wounds of the Nerves, therefore I intend to treat of them in particular. Indee they are alwayes very dangerous, and for the most part deadly, by reason of the nervous productions and membranous Tendons wherewith they are bound and engirt, and into which the Nerves are inserted: whereby it comes to passe, that the exquisite sense of such like parts will easily bring malignant symptomes, especially if the wound possesse an internall, or as they terme it, a domestique part of them; as for example, the arme pits, the bending of the arme, the inner part of the wrist, and ham, by reason of the notable Veines, Arteries and Nerves of these parts, the loosed continuity of all which brings a great flux of blood, sharpe paine and other malignant symptomes, all which we must resist according to their nature and condition, as a flux of blood with things staying bleeding; paine with anodynes. If the wound be large and wide, the severed parts shall be joynd with a suture, leaving an orifice in the lower part, by which the quittance may passe forth. This following powder of *Vigoes* description must be strewed upon the suture.

Why wounds
of the joynts
are malignant.

The cure.

R. iburis. sang. draconis, boli armen. terra sigill. an. ʒij. aloes, mastich. an. ʒj. fiat pulvis subtilis. And then the joynt must bee wrapped about with a repercussive medicine composed of the whites of egges, a little oyle of Roses, Bole, Mastich, and barley floure. If it be needefull to use a Tent, let it be short and according to the wound thicke, lest it cause paine: and moreover let it bee annointed with the yolke of an egge, oyle of Roses, washed turpentine and a little saffron. But if the wound bee more short and narrow, it shall be dilated, if there be occasion, that so the humour may passe away more freely. You must rest the part, and beware of using cold, relaxing mollifying, humecting, and unctuous medicines, unless peradventure the sharpenesse of the paine must be mitigated. For on the contrary, astringent and desiccant medicines are good, as this following cataplasme.

R. surfur. macri, farin. bordei. & fabarum. an. ʒiiij. florum cham. a. & melil. an. m. s. terebinth. ʒij. mellis communis ʒij. ol. myrtini ʒj. oxymelitis, vel oxycrat. vel luxivij com. quantum sufficit, fiat cataplasma ad formam pultis. Or you may compose one of the Lees of wine, Wheate branne, the powder of Oaken barke, cypresse nuts, galls and Turpentine and such like, that have an astringent, strengthening and drying qualitie, and thereby asswaging paine, and hindering the defluxion of humours. This following medicine is astringent and agglutinative.

An astringent
and drying
cataplasme.

R. Terebinth. venet. ʒij. aq. vitæ parum, pulveris mastich. aloes, myrrha, boli armen. an. ʒij. And also our balsame will be good in this case, if so be that, you adde hereto so much powder which dries without acrimonie as occasion shall serve. I admonished you before to take heede of cold, and now againe; for it is hurtfull to all wounds and ulcers, but especially to these of the nervous parts; hence it is that many dye of small wounds in the winter, who might recover of the same wounds though greater in the Summer. For cold according to *Hippocrates* is nipping to ulcers, hardens the skin, and hinders them from suppuration, extinguisheth naturall heate, causes blackenesse, cold aguish fits, convulsions and distentions. Now divers excrements are cast forth of wounds of the joynts, but chiefly albugineous, that is, resembling the white of an egge, and mucous, and sometime a very thinne water, all which favour of the nature of that humour which nourisheth these parts. For to every part there is appropriate for his nourishment and conservation, a peculiar Balsame, which by the wound flowes out of the same part, as out of the branches of the Vine when they are pruned, their radicall moisture or juice flowes; whence also a *Callus* proceeds in broken bones. Now this same mucous and albugineous humour, flow and as it were frozen flowing from the wounded joynts, shewes the cold distemper of the parts, which causes paine, not to be overcome by medicines onely potentially hot. Wherefore to correct

*Aphor. 20.
sect. 5.*

What matter
usually flowes
from wounds
of the joynts.

Why things
actually hot
must be apply-
ed to the
wounded
ioynts.
Of the site
and posture of
wounded
ioynts.

correct that, we must apply things actually hot, as beasts and swines bladders halfe full of a discussing decoction, or hot bricks quenched in wine. Such actuall heate helps nature to concoct and discusse the superfluous humour impact in the joynts, and strengthens them; both which are very necessary, because the naturall heate of the joynts is so infirme that it can scarce actuate the medicine unlesse it be helped with medicines actually hot. Neither must the Chirurgion have the least care of the figure and posture of the part, for a vicious posture increases ill symptomes, uses to bring to the very part though the wound be cured, distortion, nummes, incurable contraction; which fault least he should runne into, let him observe what I shall now say; If the forepart of the shoulder be wounded, a great boulster must be under the arme pit, and you must carry your arme in a scarfe, so that it may beare up the lower part of the arme, that so the top of the shoulder may be elevated somewhat higher, and that so it may be thereby more speedily and happily agglutinated and consolidated. If the lower part be wounded, when flesh begins to be generated and the lips of the wound to meete, you must bid the patient to moove and stirre his armes divers wayes ever and anon, for if that be omitted or negligently done, when it is cicatrized then it wil be more stiffe and lesse pliable to every motion; and yet there is a further danger least the arme should totally loose its motion. If the wound be upon the joynt of the elbow, the arme shall be placed and swathed in a middle posture, that is, which neither too straitly bowes it, nor holds it too stiffly out; for otherwise when it is cicatrized, there will be an impediment either in the contraction or extension. When the wound is in the wrist, or joynts of the fingers either externally or internally, the hand must be kept halfe shut, continually mooving a ball therein. For if the fingers be held straight stretched forth, after it is cicatrized, they will be unapt to take up or hold any thing, which is their proper faculty. But if after it is healed, it remaine halfe shut, no great inconvenience will follow thereon; for so hee may use his hand divers wayes to his sword, pike, bridle and in any thing else. If the joynts of the Hip be wounded, you must so place the patient that the thigh bone may be kept in the cavity of the hucklebone, & may not part a haire's breadth therefrom, which shal be done with linnen boulsters and ligatures applyed as is fitting, and lying full upon his backe. When the wound shal begin to cicatrize, the patient shall use to moove his thigh every way, least the head of the Thigh-bone sticke in the cavity of the huckle-bone without motion. In a wound of the knee, the legge must be placed straight out, if the patient desire not to be lame. When the joynts of the feete and toes are wounded, these parts shall neither be bended in nor out, for otherwise he will not be able to goe.

To conclude, the site of the foote and legge, is quite contrary to that of the arme and hand.

CHAP. XL.

Of the wounds of the Ligaments.

Ligaments
more dry than
Nerves, and
without sense.

He wounds of the Ligaments, besides the common manner of curing these of the Nerves, have nothing peculiar, but that they require more powerfull medicines, for their agglutination, desiccation and consolidating, both because the Ligamentall parts are harder, and dryer, and also for that they are voyd of sence. Therefore the foresaid cure of Nerves and joynts may be used for these wounds: for the medicines in both are of the same kinde, but here they ought to be stronger and more powerfully drying. The Theorie and cure of all the symptomes which shall happen thereupon have beene expresse in the Chapter of curing the wounds of the nervous parts, so that heere we shall neede to speake nothing of them, for there you may finde as much as you will. Wherefore here let us make an end of wounds, and give thanks to God the author and giver of all good for the happy proesse of our labours, and let us pray that, that which remaines may be brought to a happy end, and secure for the health and safety of good people.

The end of the tenth Booke.

OF VVOUNDS MADE BY GVN SHOT, OTHER FIERIE ENGEINES, AND ALL SORTS OF WEAPONS.

THE ELEVENTH BOOKE.

The Preface.

Have thought good here to premise my opinion of the originall, encrease, and hurt of fiery Engines, for that, I hope it will be an ornament and grace to this my whole treatise: as also to intice my Reader, as it were with these junkets, to our following Banquet so much favouring of Gunpowder. For thus it shall bee knowne to all whence Guns had their originall, and how many habits and shapes they have acquired from poore and obscure beginnings, and lastly how hurtfull to mankind the use of them is.

Polydore Virgill writes that a Germane of obscure birth and condition was the inventor of this new engine which we terme a Gun, being induced thereto by this occasion. He kept in a mortar covered with a tyle, or slate, for some other certaine uses a powder (which since that time for its chiefe and new knowne faculty, is named Gunpowder.) Now it chanced as hee stricke fire with a Steele and flint, a sparke thereof by accident fell into the mortar, whereupon the powder suddainly catching fire, casts the stone or tyle which covered the mortar, up on high; he stood amazed at the novelty and strange effect of the thing, and withall observed the formerly unknowne faculty of the powder; so that he thought good to make experiment thereof in a small Iron trunke framed for that purpose according to the intention of his minde. When all things were correspondent to his expectation, he first shewed the use of his engine to the Venetians, when they warred with the Genoveses about *Fossa Clodia*, in the yeare of our Lord 1380. Yet in the opinion of *Peter Messias*, their invention must have beene of greater antiquity; for it is read in the Chronicles of *Alphonfus* the eleaventh King of *Castile*, who subdued the Isles *Argezires*, that when he besieged the cheefe Towne in the yeare of our Lord 1343. the besieged Moores shot as it were thunder against the assailants, out of Iron mortars. But we have read in the Chronicles written by *Peter Bishop of Leons*, of that *Alphonfus* who conquered *Toledo*, that in a certaine sea fight fought by the King of *Tunis*, against the Moorish King of *Sivill*, whose part King *Alphonfus* favoured, the *Tunetans* cast lightning out of certaine hollow Engines or Trunkes with much noise. Which could be no other, than our Guns, though not attained to that perfection of art and execution which they now have.

*Lib. 2. de inv.
vent. et arm.*

*Cap. 8. prim.
par. 5. et 6.*

Who the inventor of Guns.

The reason of the name.

The danger of Pistolls.

I thinke the deviser of this deadly Engine hath this for his recompence, that his name should be hidden by the darkenesse of perpetuall ignorance, as not meriting for this his most pernicious invention, any mention from posterity. Yet *Andrew Thevet* in his *Cosmography* published some few yeares agoe, when hee comes to treat of the *Suevi*, the inhabitants of Germany, brings upon the authority & credite of a certaine old Manuscript, that the Germane the inventor of this warlike Engine was by profession a monke and Philosopher or Alchymist, borne at *Friburge*, and named *Constantine Anclzen*. Howsoever it was, this kind of Engine was called *Bombarda* (i) a Gun, from that noise it makes, which the Greekes and Latines according to the sound call *Bombus*; then in the following ages, time, art and mans malicioulnesse added much to this rude and unpolisht invention. For first for the matter, Brasse and Copper, mettalls farre more tractable, fusible and lesse subject to rust, came as supplies to Iron. Then for the forme, that rude and undigested barrell, or mortar-like masse, hath undergone many formes and fashions, even so farre as it is gotten upon wheelles, that so it might run not onely from the higher ground, but also with more rapide violence to the ruine of mankind; when as the first and rude mortars seemed not to bee so nimblely traversed, nor sufficiently cruell for our destruction by the onely casting forth of Iron & fire. Hence sprung these horrible monsters of Canons, double Canons, Bastards, Musquits, feild peices; hence these cruell and furious beasts, Culverines, Serpentine, Basilisques, Sackers, Falcons, Falconets, and divers other names not onely drawne from their figure and making, but also from the effects of their cruelty. Wherefore certainly I cannot sufficiently admire the wisdom of our Ancestors, who have so rightly accommodated them with names agreeable to their natures; as those who have not onely taken them from the swiftest birds of prey, as Falcons; but also from things most harmefull and hatefull to mankind, such as Serpents, Snakes, and Basilisks. That so wee might clearly discern, that these engines were made for no other purpose, nor with other intent, but onely to be imployed for the speedy and cruell slaughter of men; and that by onely hearing them named we might detest and abhorre them, as pernicious enemies of our lives. I let passe other engines of this offspring, being for their quantitie small, but so much the more pernicious and harmefull, for that they nearer assaile our lives, and may trayterously and forthwith seaze upon us not thinking nor fearing any such thing; so that we can scarce have any meanes of escape; such are Pistolls and other small hand-guns, which for shortnesse you may carry in your pocket, and so privily and suddainly taking them forth oppresse the careless and secure. Fowling peices which men usually carry upon their shoulders, are of the middle ranke of these engines, as also Muskets and Calcevers, which you cannot well discharge unlesse lying upon a Rest, which therefore may be called Breast-guns for that they are not laid to the cheeke, but against the Breast by reason of their weight and shortnesse; All which have beene invented for the commodity of footemen, and light horsemen. This middle sort of engine we call in Latine by a generall name *Sclopus*, in imitation of the sound, and the Italians who terme it *Sclopetere*; the French call it *Harquebuse*, a word likewise borrowed from the Italians, by reason of the touch-hole by which you give fire to the peice, for the Italians call a hole *Buzio*. It is tearmed, *Arum* (i) a Bow, for that at this present it holds the same place in martiall affaires, as the Bow did of old; and as the Archers formerly, so at this day the Musquetiers are placed in front. From the same wretched shoppe and magazine of cruelty, are all sorts of Mines, Countermines, pots of fire, traines, fiery Arrowes, Lances, Crossebowes, barrells, balls of fire, burning faggots, Granats, and all such fiery engines and Inventions, which closely stuffed with sewell and matter for fire, and cast by the defendants upon the bodies and Tents of the assailants, easily take fire by the violence of their motion. Certainly a most miserable and pernicious kinde of invention, whereby we often see a thousand of heedlesse men blowne up with a mine by the force of gunpowder; otherwhiles in the very heate of the conflict you may see the stoutest souldiers seazed upon with some of these fiery Engines, to burne in their harnesse, no waters being sufficiently powerfull to restraine and quench the raging and wathing violence of such fire cruelly spreading over the body and bowells. So it was not sufficient to have

armes,

armes, Iron and fire to mans destruction, unlesse also that the stroke might be more speedy, we had furnished them, as it were with wings, so to fly more hastily to our owne perdition, furnishing sithe-bearing death with wings so more speedily to oppress man, for whose preservation, all things contained in the world were created by God. Verily when I consider with my selfe all the sorts of warlike Engines, which the ancients used, whether in the field in set battells, as Bowes, Darts, Crosse-bowes, Slings; or in the assault of Citties, and shaking or overturning their walls, as Rammes, Horses, wooden towres, slings and such like; they seeme to me certaine childish sports and games made onely in imitation of the former. For these moderne inventions are such as easily exceede all the best appointed and cruell Engines which can bee mentioned or thought upon, in the shape, cruelty and appearance of their operations. For what in the world is thought more horrid or fearefull than thunder and lightning? and yet the hurtfulnesse of thunder is almost nothing to the cruelty of these infernall Engines; which may easily appeare by comparing together both their effects. Man alone of all creatures is not alwayes killed by being touched with thunder; but it immediatly killeth all other things which are subject to bee toucht therewith.

A comparison
of the ancient
weapons with
the moderne,

Plin. Lib. 2.
Cap. 59.

Nature bestowing this honour upon him, seeing so many creatures exceede him in strength: For all things ly contrary to man; and man, unlesse hee bee overthrowne with it, doth not dye thereof. But these fire-spitting Engines doe no more spare man, than they doe other creatures, and kill without difference from whence soever they come, whither soever they are carried, and howsoever they touch. There are many, but more are said to be the remedies against thunder; for beside the charmes whereby the ancient Romans did suppose they might be driven away, they never penetrate deeper into ground than five foote, therefore such as were fearefull thought the deeper Caves most safe. Of those things which grow out of the earth they doe not touch the Bay tree, and that was the cause that it was counted a signe of victory both in ancient and moderne times. Wherefore *Tiberius Caesar* otherwise a contemner of God and religion, as hee who indued with the Mathematicall sciences thought all things governed by fate, yet because hee exceedingly feared thunder, hee alwayes carried a Lawrell wreath about his necke when the aire was troubled, for that this kind of leafe is reported not to be touched by thunder. Some report that he made him tents of Seales skinnes, because it toucheth not this kinde of creature of all these things that live in the Sea, as neither the Eagle amongst birds, which for that is fained to be *Joves* squire. But on the contrary, charmes, the victorious Bay, the Seale or Sea-calse, the Eagle or any such thing profits nothing against the violence of these fiery Engines: no not a wall of tenne foote thicke will advantage. Lastly, this argues the immense violence of brasen Cannons above thunder, for that thunder may be disperfed and driven away with the noyse and ringing of Bells, the sounding of Trumpets, the tinkling of brasen kettles, yea also by the shooting of such great Ordinance; to wit, the clouds, by whose collision and fight the Thunder is caused, being disperfed by this violent agitation of the ayre, or else driven further to more remote parts of the skies. But their fury once provoked, is stayed by no opposition, appeased by no remedy. As there are certaine seasons of the yeare, so also there are certaine Regions of the earth, wherein Thunder is seldome or never heard. Thunders are rare in Winter and Summer, and that for contrary causes; for that in Winter the dense aire is thickned with a thicker coate of clouds, and the frosty and cold exhalation of the earth extinguisheth what fiery vapours soever it receives; which thing keepes *Scythia* and the cold countries about it free from Thunder. And on the contrary, too much heate preserves Egypt. For hot and dry exhalations of the earth are condensed into very thinne, subtil and weake clouds. But as the invention, so also the harme and tempest of great Ordinance, like a contagious pestilence is spread and rages over all the earth, and the skies at all times sound againe with their reports. The Thunder and Lightning commonly gives but one blow, or stroke, and that commonly strikes but one man of a multitude; But one great Cannon at one shot may spoyle and kill an hundred men. Thunder, as a thing naturall falls by chance, one while upon an high oake, another while upon the top of a moun-

Cap. 50.

taine,

raine, and somewhiles on some lofty towre, but seldome upon man. But this hellish Engine tempered by the malice and guidance of man, assailes man onely, and takes him for his onely marke, and directs his bullets against him. The Thunder by its noyse as a messenger sent before, foretells the storme at hand; but, which is the chiefe mischief, this internall Engine roares as it strikes, and strikes as it roares, sending at one and the same time the deadly bullet into the breast, and the horrible noyse into the eare. Wherefore we all of us rightfully curse the author of so pernicious an Engine; on the contrary praise those to the skies, who endeavour by words and pious exhortations to dehort Kings from their use, or else labour by writing and operation to apply fit medicines to wounds made by these Engines. Which hath moved me, that I have writtē hereof almost with the first of the French. But before I shall doe this, it seemeth not amisse, so to facilitate the way to the treatise I intend to write of wounds made by Gunshot, to premise two Discourses, by which I may confute and take away certaine erronious opinions which have possessed the mindes of divers; for that unlesse these be taken away, the essence and nature of the whole disease cannot be understood, nor a fitting remedy applied by him which is ignorant of the disease.

The arguments of the following discourses.

The first Discourse which is dedicated to the Reader, refells and condemnes by reasons and examples the method of curing prescribed by *Iohn de Vigo*, whereby he cauterizes the wounds made by Gunshot, supposing them venenate, and on the contrary proves that order of curing with is performed by suppuratives, to be so salutary and gentle, as that prescribed by *Vigo* is full of error and cruelty.

The second dedicated to the King, teaches that the same wounds, are of themselves voyd of all poison, and therefore that all their malignity depends upon the fault of the aire, and ill humours predominant in the bodies of the patients.

THE FIRST DISCOVRSE, VVHEREIN VVOVNDVS MADE BY GVNSHOT, ARE FREED FROM BEING BVRNT, OR CAUTERIZED ACCOR- ding to *Vigoes* Methode.

IN the yeare of our Lord 1536. *Francis* the French King, for his acts in warre and peace stiled the Great, sent a puissant Army beyond the Alpes, under the government and leading of *Annas* of Mommorancie high Constable of France, both that he might relieve *Turin* with victualls, souldiers, and all things needefull, as also to recover the Citties of that Province taken by the Marquis of *Guaft* Generall of the Emperours forces. I was in the Kings Army the Chirurgeon of Monsieur of *Montejan* Generall of the foote. The Imperialists had taken the straits of *Suze*, the Castle of *Villane*, and all the other passages; so that the Kings army was not able to drive them from their fortifications but by fight. In this conflict there were many wounded on both sides with all sorts of weapons, but chiefly with bullets. I will tell the truth, I was not very expert at that time in matters of Chirurgery; neither was I used to dresse wounds made by Gunshot. Now I had read in *Iohn de Vigo* that wounds made by Gunshot were venenate or poisoned, and that by reason of the Gunpowder, Wherefore for their cure, it was expedient to burne or cauterize them with oyle of Elders scalding hot, with a little Treacle mixed there-
with.

with. But for that I gave no great credite neither to the author, nor remedy, because I knew that causticks could not be powred into wounds, without excessive paine; I, before I would runne a hazard, determined to see whether the Chirurgions, who went with me in the army, used any other manner of dressing to these wounds. I observed and saw that all of them used that Method of dressing which *Vigo* prescribes; and that they filled as full as they could, the wounds made by Gun-shot with Tents and pledgets dipped in this scalding Oyle, at the first dressings; which encouraged me to doe the like to those, who came to be dressed of me. It chanced on a time, that by reason of the multitude that were hurt, I wanted this Oyle. Now because there were some few left to be dressed, I was forced, that I might seeme to want nothing, and that I might not leave them undrest, to apply a digestive made of the yolke of an egge, oyle of Roses, and Turpentine. I could not sleepe all that night, for I was troubled in minde, and the dressing of the precedent day, (which I judged unfit) troubled my thoughts; and I feared that the next day I should finde them dead, or at the point of death by the poyson of the wound, whom I had not dressed with the scalding oyle. Therefore I rose early in the morning, I visited my patients, and beyond expectation, I found such as I had dressed with a digestive onely, free from vehemencie of paine to have had good rest, and that their wounds were not inflamed, nor tumified; but on the contrary the others that were burnt with the scalding oyle were feaverish, tormented with much paine, and the parts about their wounds were swolne. When I had many times tryed this in divers others, I thought thus much, that neither I nor any other should ever cauterize any wounded with Gun-shot. When wee first came to *Turin*, there was there a Chirurgeon farre more famous than all the rest in artificially and happily curing wounds made by Gun-shot; wherefore I laboured with all diligence for two yeeres time to gaine his favour and love, that so at the length, I might learne of him, what kinde of Medicine that was, which he honoured with the glorious tittle of Balsame, which was so highly esteemed by him, and so happy and succesfull to his patients; yet could I not obtaine it. It fell out a small while after that the Marshall of *Montejan* the Kings Leiftenant, Generall there in *Piemont* dyed, wherefore I went unto my Chirurgeon, and told him that I could take no pleasure in living there, the favourer and *Mecenas* of my studies being taken away; and that I intended forthwith to returne to *Paris*, and that it would neither hinder, nor discredit him to teach his remedy to me, who should be so farre remote from him. When he heard this, he made no delay, but presently wished mee to provide two Whelpes, 1 pound of earth-wormes, 2 pounds of oyle of Lillyes, sixe ounces of Venice Turpentine, and one ounce of *aqua vite*. In my presence he boyled the Whelpes put alive into that oyle, untill the flesh came from the bones, then presently he put in the Wormes, which he had first killed in white wine, that they might so be cleaved from the earthy drosse wherewith they are usually replete, and then hee boyled them in the same oyle so long, till they became dry, and had spent all their juyce therein: then hee strayned it through a towell without much pressing; and added the Turpentine to it, and lastly the *aqua vite*. Calling God to witnesse, that he had no other Balsame, wherewith to cure wounds made with Gunshot, and bring them to suppuration. Thus he sent me away as rewarded with a most pretious gift, requesting me to keepe it as a great secret, and not to reveale it to any.

What chance

remedies.

The description
on of oyle of
Whelpes.

When I came to *Paris*, I went to visite *Silvius* the Kings professor of Physicke well knowne by name to all schollers for his great learning; he kept me long that so I might dine with him, and diligently enquires of me, if I had observed any new Method of curing wounds made by Gun-shot, and combustions occasioned by Gun-powder. Then I affirmed to him that Gun-powder did not participate any thing of poyson, for that none of these things, whereof it is compounded are poysonous; which reason ought to free the whole composition from suspicion of poyson. And that experience confirmed this reason, for I had seene many soldiers, who would drinke a great quantity of this powder with wine, because they were perswaded, that this drinke would free them from malignant symptomes when they were wounded, yet I give no credit to this perswasion, and lastly for that many with-

Gun-powder
not poysonous.

Bullets shot
out of a Gun
doe not burne.

out any harme, strew this powder upon rebellious ulcers. For the Bullets, I affirme, that they cannot conceive such heate, as to become causticke. For if you shoot them out of a Gun against a hard stone, yet you may presently take them up without any harme in your hands, though by striking upon the stone, they should become more hot. For the combustions caused by Gunpowder, I observed no speciall nor peculiar remedy, which might make their cure different from other combustions. To which purpose I related this ensuing history.

A Historie

A medicine
hindring blis-
string in
burnes, or
scalds.

One of the Marshall of *Montejan* his Kitchin boyes, fell by chance into a Caldron of Oyle being even almost boyling hot; I being called to dresse him, went to the next Apothecaries to fetch refrigerating medicines commonly used in this case: there was present by chance a certaine old countrey woman, who hearing that I desired medicines for a burne, perswaded mee at the first dressing, that I should lay to raw Onions beaten with a little salt; for so I should hinder the breaking out of blisters or pustules, as shee had found by certaine and frequent experience. Wherefore I thought good to try the force of her Medicine upon this greasy scullion. I the next day found those places of his body whereto the Onions lay, to bee free from blisters, but the other parts which they had not touched, to be all blistered.

A Historie.

It fell out a while after, that a German of *Montejan* his guard had his flasque full of Gunpowder set on fire, whereby his hands and face were grievously burnt: I being called, laid the Onions beaten as I formerly told you, to the middle of his face, and to the rest I laid medicines usually applied to burnes. At the second dressing I observed the part dressed with the Onions quite free from blisters and excoriation, the other being troubled with both; whereby I gave credit to the Medicine. Besides also, I lastly told him this, that I had observed, that that was the readiest to draw forth bullets shot into the body, which sets the patients in the same posture and site, as hee was when hee received his hurt. Which things when I had told him, together with many other handled at large in this worke, the good old man requested mee to publish in print my opinions concerning these things, that so the erroneous and hurtfull opinion of *Vigo* might bee taken out of mens minds. To whose earnest entreaty when I had assented, I first of all caused to be drawne and carved many Instruments fit to draw forth Bullets and other strange bodies; then a short while after I first published this worke in the yeare of our Lord 1545. which when I found to bee well liked and approved by many, I thought good to set it forth the second time somewhat amended in the yeare 1552. And the third time augmented in many particulars in the yeare 1564. For I having followed many warres, and deteined as Chirurgeon in besieged Cities, as *Mets* and *Hesdin*, had observed many things under five Kings, whom I served with diligence and content. I had learnt many things from most expert Chirurgeons, but more from all learned Physitions, whose familiarity and favour for that purpose I alwayes laboured to acquire with all diligence and honest Arts; that so I might become more learned and skillfull by their familiarity and discourse, if there was any thing especially in this matter and kind of wounds, which was hid from me, or whereof I was not well assured. Of which number I have knowne very few, who any thing seene in this kind of operation eyther by study, or experience in Warres, who have not thought that wounds made by Gunshot ought to be dressed at the first with suppurative medicines, and not with scalding and Causticke Oyle.

Wounds made
by Gunshot
must be dress-
ed with sup-
puratives.

The causes of
difficultie in
this cure.

For this I affirme, which then also I testified to this good man, that I have found very many wounds made in the fleshy parts by Gunshot, as easily cured as other wounds, which bee made by contusing things. But in the parts of the body where the bullet meets with bones and nervous particles, both because it teares and rends into small peeces those things which resist, not onely where it rouches, but further also, through the violence of the blow, therefore it causerh many and greivous symptomes, which are stubborne and difficult, and oft times impossible to cure, especially in bodies replete with ill humors, in an ill constitution of the heaven and ayre, such as is hot, moyst and foggy weather,

ther, which therefore is subject to putrifaction; and in like manner a freezing and cold season, which uses to mortifie the wounded parts not onely of those that are hurt with Bullets, but in like sort with any other weapon; nor onely in bony and nervous particles, but also in musculous. Whereby you may understand, that the difficulty of curing proceeds not from the venenate quality of the wounds, nor the combustion made by the Gunpowder, but the foulness of the patients bodies, and the unseasonableness of the aire.

For prooffe whereof, I will set downe, that which I not long agoe observed in a *A Historie*, Scottish Nobleman the Earle of *Gordon*, Lord of *Achindon*, whom I cured at the appointment of the Queene Mother. He was shot through both his thighs with a Pistoll, the bone being not hurt nor touched; and yet the 32. day after the wound he was perfectly healed, so that hee had neither feaver nor any other symptome which came upon the wound. Whereof there are worthy witnesses, the Archbishop of *Glasco*, the Scottish Embassadour, *Francis Brigart* and *John Altine*, Doctors of Physicke, as also *James Guillemeau* the Kings Chirurgeon, and *Giles Buzet* a Scottish Chirurgeon, who all of them wondred that this Gentleman was so loone healed, no acride medicine being applyed. This I have thought good to recite and set downe, that the Readers may understand, that I for 30. yeares agoe had found the way to cure wounds made by Gunshot, without scalding oyle or any other, more acrid medicine; unlesse by accident the illness of the patients bodies and of the aire caused any malignant symptomes, which might require such remedies besides the regular and ordinary way of curing, which shall bee more amply treated of in the following discourse.

What makes
Chirurgions
sometimes use
causticks in
curing
wounds made
by Gunshot.

ANOTHER DISCOURSE OF THESE THINGS, WHICH KING CHARLES THE NINTH, RE- turning from the expedition and taking of *Rouen*, enquired of me concerning wounds made by Gunshot.

Or that it pleased your Majestie one day, together with the Queene Mother, the Prince of the *Roche upon Ton*, and many other Noble-men and Gentlemen, to enquire of mee, what was the cause that the farre greater part of the Gentlemen and common Souldiers which were wounded with Guns, and other warlike Engines, all remedies used in vaine, either dyed, or scarce and that with much difficultie recovered of their hurts, though in appearance they were not very great, and though the Chirurgions diligently performed all things

The occasion
of writing
this discourse,

requisite in their Art; I have made bold to premise this Discourse to that Tractate which I determine to publish concerning wounds made by Gunshot; both to satisfie the desires of the Princes and of many Gentlemen, as also the expectation they have of mee, as being the Kings chiefe Chirurgeon, (which place being given me by *Henry* the second, *Charles* the ninth, a sonne most worthy of such a father, had confirmed) neither make I any question, but that many who too much insist upon their owne judgement, and not thoroughly consider the things themselves, will

The argument
of this dis-
course.

marvaile, and thinke it farre from reason; that I departing from the steps of my ancestors, and dissenting wholly from the formerly received opinions, am farre from their Tenents, who lay the cause of the malignitie of wounds made by Gunshot, upon the poyson brought into the body by the Gunpowder, or mixed with the Bullets whilst they are tempered or cast. Yet for all this, if they will courteously and patiently weigh my reasons, they shall eyther thinke as I doe, or at least shall judge this my endeavour and paines taken for the publike good, not to be condemned nor contemned.

Gunpowder is
not poyson
nous,

For I shall make it evident by most strong reasons drawne out of the writings of the Ancient both Philosophers and Physitions, and also by certaine experiments of mine owne, and other Chirurgions, that the malignitie and contumacie which we frequently meete withall in curing wounds made by Gunshot, is not to be attributed eyther to the poyson carryed into the body by the Gunpowder or Bullet, nor to burning imprinted in the wounded part by the Gunpowder. Wherefore to come to our purpose, that opinion must first bee confuted, which accuseth wounds made by Gunshot of poyson; and wee must teach, that there is neither any venenate substance, nor qualitie in Gunpowder, neyther if there should bee any, could it empoison the bodies of such as are wounded. Which that wee may the more easily performe, wee must examine the composition of such powder, and make a particular enquiry of each of the simples, whereof this composition consists, what essence they have, what strength and faculties, and lastly what effects they may produce. For thus by knowing the simples, the whole nature of the composition consisting of them, will bee apparently manifest.

Of what it
is made.

The simples which enter the composition of Gunpowder are onely three, Charcoales of Sallow or Willow, or of Hempe stalkes, Brimstone, and salt Peter, and sometimes a little *aqua vita*. You shall finde each of these, if considered in particular, voide of all poyson and venenate quality. For first, in the Char-coale you shall observe nothing but drynesse, and a certaine subtlety of substance, by meanes whereof it fires so suddainly, even as Tinder. Sulphur or Brimstone is hot and dry, but not in the highest degree, it is of an oily and viscid substance, yet so that it doth not so speedily catch fire as the coale, though it reteine it longer being once kindled, neither may it be so speedily extinguished. Salt Peter is such, that many use it for Salt, whereby it is evidently apparent that the nature of such simples is absolutely free from all poyson; but chiefly the Brimstone, (which notwithstanding is more suspected than the rest.) For *Dioscorides* gives Brimstone to be drunke, or supped out of a reare Egge to such as are Asthmaticke, troubled with the Cough, (spit up purulent matter, and are troubled with the yellow laundise.) But *Galen* applies it outwardly to such as are bitten by venomous Beasts, to scabs, teaters, and leprosy. For the *aqua vita*, it is of so tenuious a substance that it presently vanisheth into aire, and also very many drinke it, and it is without any harme used in frictions of the exteriour parts of the body. Whence you may gather, that this powder is free from all manner of poyson, seeing these things whereof it consists and is composed, want all suspicion thereof.

Lib. 5. Cap. 73.
Lib. 9. simpl.
Cap. 36.

Bullets cannot
be poysoned.

Therefore the Germane horsemen, when they are wounded with shot, feare not to drinke off cheerefully halfe an ounce of Gunpowder dissolved in wine; hence perswading themselves freed from such maligne symptomes as usually happen upon such wounds; wherein whether they doe right or wrong I doe not here determine; the same thing many French Souldiers forced by no necessity, but onely to shew themselves more couragious, also doe without any harme; but divers with good successe use to strew it upon ulcers, so to dry them. Now to come to these, who thinke that the venenate quality of wounds made by Gunshot, springs not from the powder, but from the Bullet wherewith some poyson hath beene commixt or joyned, or which hath beene tempered or steeped in some poysonous liquor.

This may sufficiently serve for a reply; that the fire is abundantly powerfull to dissipate all the strength of the Poyson, if any should bee poured upon

or added to the Bullet. This much confirms mine opinion, which every one knowes; The Bullets which the Kings souldiers used to shoote against the Townesmen in the siege of Rouen, were free from all poyson; and yet for all that they of the Towne thought that they were all poysoned, when they found the wounds made by them, to be incurable and deadly. Now on the other side the Townesmen were falsely suspected guilty of the same crime by the Kings Army, when as they perceived all the Chirurgions labour in curing the wounds made by the Bullets shot from Rouen, to be frustrated by their contumacy and maligne nature; each side judging of the magnitude and malignitie of the cause from the unhappy successe of the effect in curing. Even as amongst Physitions according to *Hippocrates*, all diseases are termed pestilent, which arising from whatsoever common cause, kill many people; so also wounds made by Gunshot, may in some respect be called pestilent, for that they are more refractory, and difficult to cure than others, and not because they partake of any poysonous qualitie, but by default of some common cause, as the ill complexions of the patients, the infection of the aire, and the corruption of meats and drinckes. For by these causes wounds acquire an evill nature and become lesse yeelding to medicines. Now we have by these reasons convinced of errour that opinion which held wounds made by Gunshot for poysonous; let us now come to overthrow that which is held concerning their combustion.

First it can scarce be understood how bullets which are commonly made of Lead, can attaine to such heate, but that they must be melted; and yet they are so far from melting, that being shot out of a Musket they will peirce through an armour and the whole body besides, yet remaine whole, or but a little diminisht. Besides also if you shoote them against a stone wall, you may presently take them up in your hand without any harme, and also without any manifest sence of heate; though their heate by the striking upon the stone should bee rather encreased, if they had any.

Furthermore, a Bullet shot into a barrell of Gunpowder, would presently set it all on fire, if the Bullet should acquire such heate by the shooting, but it is not so. For if at any time the powder be fired by such an accident, wee must not imagine that it is done by the bullet bringing fire with it, but by the striking and collision thereof against some Iron, or stone that opposes or meets therewith, whence sparkes of fire proceeding as from a flint, the powder is fired in a moment. The like opinion wee have of thatched houses, for they are not fiered by the bullet which is shot, but rather by some other thing as linnen ragges, browne paper, and the like, which rogues and wicked persons fasten to their Bullets. There is another thing which more confirms mee in this opinion, which is; take a bullet of Waxe, and keepe it from the fire, for otherwise it would melt, and shoote it against an inch board, and it will goe through it; whereby you may understand that Bullets cannot become so hot by shooting, so burne like a cautery. But the Orifices (may some say) of such wounds are alwayes blacke. This indeede is true, but it is not from the effect of heate brought thither by the Bullet, but the force of the contusion.

Now the contusion is exceeding great, both because the Bullet is round, and enters the body with incredible violence. Of which those that are wounded will give you sufficient testimony, for there is none of them, which thinks not presently upon the blow, that as it were some post, or thing of the like weight, falls upon the affected member, whence great paine and stupiditie possesse the part, whereby the native heate and spirits are so much dissipated, that a Gangreen may follow.

But for the Eschar which they affirme is made by the blow, and falls away afterwards, they are much mistaken. For certaine particles of the membranes and flesh contused and torne by the violence of the Bullet beguiles them; which presently putrifying are severed from the sound parts by the power of nature and the separating heate, which thing usually happens in all great Contusions. But for all that these so many and weighty reasons may free the Powder from all suspicion of Poison, and the Bullet from all thought of burning;

A Historie

Why the
wounds made
by Gunshot
some few
yeares agoe
were so dead-
ly.

yet there are many who insisting upon Philosophicall arguments, raise new stirrs. For (say they) the discharging a peice of Ordinance is absolutely like Thunder and Lightning, which the rent and torne clouds cast from the middle region, upon the earth; wherefore the Iron bullet which is shot out of the Cannon must needs have a venenate and burning faculty. I am not ignorant that Lightnings generated of a grosse and viscous exhalation, breaking the cloud wherewith it is encompassed, never falls upon the earth, but brings fire with it, one while more subtile, another while more grosse, according to the various condition of the matter whence the exhalation hath arisen. For *Seneca* writes that there are three severall kinds of Lightning differing in burning, condition and plenty. One of them penetrates or rather perforates by the tenuity of the matter of the objects which it touches. The other with a violent impetuosity breakes insunder and dissipates the objects, by reason it hath a more dense, compact and forcible matter, like as Whirlewinds have. The third, for that it consists of a more terrestriall matter, burnes what it touches, leaving behind it the impression of the burning. Also I know that Lightning is of a pestilent and stinking nature, occasioned by the grossenesse and viscosity of the matter whereof it is; which matter taking fire sends forth so lothsome and odious a smell that the very wilde-beasts cannot endure it; but leave their Dennes, if they chance to be touched with such a lightening. Besides also, we have read in the northerne history of *Olaus Magnus*, that in some places after a Lightning, you shall finde a whole plaine spread over with Brimstone, which Brimstone notwithstanding is extinguished, unprofitable & of no efficacie. But grant these things be thus, yet must we not therefore conclude, that the Bullets of the great Ordinance carry poyson and fire with them into the wounds. For though there be many things like in Lightning and discharging great Ordinance, yet they have no similitude either in matter or substance, but onely in effects whereby they shake, breake insunder and disperse the bodies which withstand them; For Lightning and Thunder doe it by meanes of fire, and oft times of a stone generated in them, which is therefore tearmed, a Thunderbolt; But Ordinance by the bullet carried by the force of the aire, more violently driving and forcing it forwards; Neither if any should by more powerfull arguments force me to yeeld that the matter of Lightning and shooting of Ordinance are like, yet will I not therefore be forced to confesse that wounds made by Gunshot are combust. For according to *Pliny*, there are some Lightnings which consisting of a most dry matter, doe shatter in sunder all that withstands them, but doe not burne at all; others which are of somewhat a more humid nature, burne no more than the former, but onely blacke such things as they touch; Lastly othersome of a more subtile and tenuous matter, whose nature (as *Seneca* saith) wee must not doubt to be divine, if but for this reason, that they will melt gold and silver, not harming the purse; a sword, not hurting the scabbard; the head of a Lance, not burning the wood, and shed wine not breaking the vessell. According to which decree I can grant, that these Lightnings which breake in sunder, melte and dissipate, and performe other effects so full of admiration, are like in substance to the shot of great Ordinance; but not these which carry with them fire and flame.

In proote whereof there comes into my minde the historie of a certaine Souldier, out of whose thigh I remember I drew forth a Bullet wrapped in the taffety of his breeches, which had not any signe of tearing or burning. Besides, I have scene many who not wounded, nor so much as touched, yet notwithstanding have with the very report & winde of a Cannon bullet, sliding close by their eares, fallne downe for dead, so that their members becomming livid & black, they have dyed by a Gangrene ensuing thereupon. These and such effects are like the effects of Lightnings which wee lately mentioned, and yet they beare no signe nor marke of poyson. From whence I dare now boldly conclude, that wounds made by Gunshot are neither poysoned, nor burnt. But seeing the danger of such wounds in these last civill warres hath beene so great, universall and deadly to so many worthy personages and valiant men, what then may have beene the cause thereof, if it were neither combustion, nor the venenate qualitie of the wound? This must wee therefore now insist upon and somewhat hardily explaine.

Those

Those who have spent all their time in the learning and searching out the mysteries of Naturall Philosophie, would have all men thinke and beleeeve, that the foure Elements have such mutuall sympathy, that they may bee changed each into other; so that they not onely undergoe the alterations of the first qualities which are heate, coldnesse, drynesse and moisture, but also the mutation of their proper substances by rarefaction and condensation. For thus the fire is frequently changed into ayre, the ayre into water, the water into aire, and the water into earth; and on the contrary, the earth into water, the water into aire, the aire into fire; because these 4. first bodies have in their common matter enjoyed the contrary and fighting, yet first and principall qualities of all.

Whereof we have an example in the * Ball-bellows brought out of Germany, which are made of brasse, hollow and round; and have a very small hole in them, whereby the water is put in, and so put to the fire; the water by the action thereof is rarified into aire, and so they send forth winde with a great noyse, and blow strongly as soone as they grow thoroughly hot. You may try the same with Chesnuts, which cast whole and undivided into the fire, presently fly asunder with a great cracke; because the watry and innate humidity turned into winde by the force of the fire, forcibly breakes his passage forth. For the aire or winde raised from the water by rarification, requires a larger place, neither can it now bee contained in the narrow filmes, or skinnes of the Chesnut, wherein it was formerly kept. Just after the same manner Gunpowder being fiered, turns into a farre greater proportion of ayre, according to the truth of that Philosophicall proposition, which saith, Of one part of earth, there are made ten of water; of one of water, ten of aire; and of one of aire are made ten of fire. Now this fire not possible to be pent in the narrow space of the peice, wherein the powder was formerly contained, endeavours to force its passage with violence, and so casts forth the Bullet lying in the way, yet so that it presently vanishes into aire, and doth not accompany the Bullet to the marke, or object, which it batters, spoiles and breakes asunder. Yet the Bullet may drive the obvious aire with such violence, that men are often sooner touched therewith than with the bullet, and dye by having their bones shattered and broken without any hurt on the flesh which covers them; which as wee formerly noted, it hath common with Lightning. We finde the like in Mines, when the powder is once fiered, it remooves and shakes even mountaines of earth.

In the yeare of our Lord 1562 a quantity of this powder which was not very great, taking fire by accident in the Arcenall of Paris, caused such a tempest, that the whole Citty shoke therewith, but it quite overturned divers of the neighbouring houses, and shooke off the tyles and broke the windowes of those which were further off; and to conclude, like a storme of Lightning it laid many here and there for dead, some lost their sight, others their hearing, and other some had their limbes torne asunder, as if they had beene rent with wilde horses; and all this was done by the onely agitation of the aire into which the fiered Gunpowder was turned; Just after the same manner as windes pent up in hollow places of the earth which want vents. For in seeking passage forth, they vehemently shake the sides of the Earth, and raging with a great noise about the cavities, they make all the surface thereof to tremble; so that by the various agitation one while up, another downe, it overturnes or carries it to another place. For thus we have read that *Megara* and *Agina* anciently most famous Citties of Greece, were swallowed up and quite overturned by an earthquake; I omit the great blusterings of the windes striving in the cavities of the earth, which represent to such as heare them at some distance, the fierce assailing of Citties, the bellowing of Bulles, the horrid roarings of Lions, neither are they much unlike to the roaring reports of Cannons. These things being thus premised let us come to the thing we have in hand.

Amongst things necessary for life, there is none causes greater changes in us than the aire; which is continually drawne into the Bowells appointed by nature, and whether we sleepe, wake, or what else soever we doe, we continually draw in, and breath it out. Through which occasion *Hippocrates* calls it Divine, for that breathing through this mundane Orbe, it embraces, nourishes, defends and keepe in quiet peace all things

The cause of the transmutation of the Elements.

* These bellows here mentioned by the Author, are Bals made of Brasse in forme of a pearce, with a very small hole in their lesser ends: when you would fill them with water you must heate them very hot, and so the aire which is contained in them will be exceedingly rarified, which by putting them presently into water will be condensed as much, and so will draw in the water to supply the place, *ne desur Sacrum*. Then put them into the fire, and it againe rarifying the water into aire will make them yeelde a strong continued and forcible blast. The cause of the report and blow of a Cannon. A Historie. The cause of an Earthquake.

How the aire
becomes hurt-
full.

maritime pla-
ces.

things contained therein, friendly conspiring with the starres from whom a divine vertue is infused therein. For the aire diversly changed and affected by the starres, doth in like manner produce various changes in these lower mundane bodies. And hence it is that Philosophers and Physitions doe so seriously wish us to behold and consider the culture and habite of places, and constitution of the aire, when they treat of preserving of health, or curing diseases. For in these the great power and dominion of the aire is very apparent, as you may gather by the foure seasons of the year; for in summer the aire being hot and dry, heats and dries our bodies; but in winter it produceth in us the effects of winters qualities, that is, of cold and moisture; yet by such order and providence of nature, that although according to the varieties of seasons our bodies may be variously altered, yet shall they receive no detriment thereby, if so be that the seasons retaine their seasonableness; from whence if they happen to digresse, they raise and stirre up great perturbations both in our bodies and mindes; whose malice we can scarce shunne, because they encompass us on every hand, and by the law of nature enter together with the aire into the secret cabinets of our bodies both by occult and manifest passages. For who is he, that doth not by experience finde both for the commodity and discommodity of his health, the various effects of winds, (wherewith the aire is commixt) according as they blow from this or that Region, or Quarter of the world. Wherefore seeing that the South winde is hot and moist; the North wind cold and dry; the East wind cleare and fresh; the West winde cloudy; it is no doubt but that the aire which we draw in by inspiration carries together therewith into the bowells the qualities of that winde which is then prevalent. When wee reade in *Hippocrates*, that changes of times whether they happen by different windes, or vicissitude of seasons, chiefly bring diseases; For northerly winds doe condense, and strengthen our bodies, and makes them active, well coloured and daring, by resuscitating and vigorating the native heate. But southerne windes resolve and moisten our bodies, make us heavy, headed, dull the hearing, cause giddinesse, and make the eyes and body lesse agile; as the Inhabitants of *Narbon* finde to their great harme, who are otherwise ranked among the most active people of France. But if wee would make a comparison of the seasons and constitutions of a year, by *Hippocrates* decree Droughts are more wholesome and lesse deadly than Raines; I judge for that too much humiditie is the mother of putrefaction, as you learne by these countries which are blowne upon by a winde from Sea: For in these flesh which is kept for foode, putrefies in the space of an houre; and such ulcers as in other places are easily and quickly healed, doe there by the conflux and collection of matter become inveterate and contumacious. Therefore as when the seasons of the year successively fall out agreeable to their nature, and when each season is seasonable, then either we are not sicke at all, or assuredly with lesse danger. So on the contrary the perfect constitution and health of our bodies becomes worse and decays, when the seasons of the year are depraved and perverted in time and temper.

Now seeing that these many yeares the foure seasons of the year have wanted their seasonableness, the summer wanting his usuall heate, and the winter its cold, and all things by moisture and the dominion of the southerne windes have beene humid and languide; I thinke there is none so ignorant in naturall Philosophie and Astrologie, who will not thinke that the causes of the malignitie and contumacie of those diseases which have so long afflicted all France, are not to bee attributed to the aire and Heavens. For otherwise, whence have so many pestilent and contagious diseases tyrannized over so many people of every age, sex and condition? whence have so many catarrhes, coughs and heavinesses of the head, so many pleurisies, tumors, small poxes, meazells, and Itches not admitting of digestion and remedies prescribed by Art? Whence have we had so many venomous creatures, as Toades, Grasshoppers, Caterpillers, Spiders, Wasps, Hornets, Beetles, Snailles, Vipers, Snakes, Lizards, Scorpions and Efts or Nutes, unlesse from excessive putrefaction which the humidity of the aire, our native heate being liquid and dull, hath caused in us, and the whole kingdome of France? Hence also procedes the infirmity of our native heate, and the corruption of the blood and humors whereof we consist, which

the

the rainy Southwind hath caused with its sultry heate. Wherefore in these last yeares I have drawne little blood, which hath not presently shewed the corruption of its substance by the blacke or greenish colour, as I have diligently observed in all such as I have bled, by the direction of Physicians, either for prevention of future, or cure of present diseases. Whence it comes to passe that the fleshy substance of our bodies could not but be faulty both in temper and consistence; seeing that the blood whence it is generated had drawne the seeds of corruption from the defiled aire. Whence it fell out, that the wounds which happened with losse of substance, could be scarce healed or united, because of the depraved nature of the blood. For so the wounds and ulcers of these which are troubled with the Droptic, whose blood is more cold or wholly waterish; so of Leprous persons, whose blood is corrupt, and lastly of all such as have their bodies replete with ill juice, or else are Cachecticke, will not easily admit of cure. Yea assuredly if but the very part which is hurt swerve from its native temper, the wound will not easily be cured.

In what sort
dies ulcers and
wounds are
not easily
cured.

Therefore seeing all these things, both the putrefaction of the Aire, and depraved humors of the body, and also the distemper of the affected parts conspired together to the destruction of the wounded, what marvaile was it, if in these late civil wars, the wounds which were for their quantity small, for the condition of the wounded parts but little, have caused so many and grievous accidents and lastly death it selfe? Especially, seeing that the Aire which encompasseth us, tainted with putrefaction corrupts and defiles the wounds by inspiration and expiration, the body and humours being already disposed, or inclined to putrefaction.

Now there came such a stinke, which is a most assured signe of putrefaction, from these wounds when they were dressed, that such as stood by could scarce endure it, neither could this stinke be attributed to the want of dressing, or fault of the Chirurgeon; for the wounds of the Princes and Nobility stunk as ill as these of the common Souldiers. And the corruption was such, that if any chanced to be undrest for one day, which sometimes happened amongst such a multitude of wounded persons, the next day the wound would be full of wormes. Besides also, which furthermore argues a great putrefaction of humors, many had Abscesses in parts opposite to their wounds, as in the left knee, when as the right shoulder was wounded; in the left arme, when as the right Leg was hurt. Which I remember befell the King of Navarre, the Duke of Newers, the Lord Rendan and divers others. For all men had nature so overcharged with abundance of vicious humors, that if it expelled not part thereof by impostumes to the habite of the body, it certainly otherwise disposed of it amongst the inner parts of the body; for in dissecting dead bodies, wee observed that the Spleene, Liver, Lungs, and other Bowells were purulent, and hence it was that the patients by reason of vapours sent from them to the heart were troubled with continuall feavers. But the Liver and all the veinous parts being polluted, and so the generation of the laudible blood hindered, they languished for want of fitting nourishment. But when the Braine by vapours was drawne in to sympathize with the rest, they were molested with Ravings and Convulsions. Wherefore if any thing succeeded unprosperously in so great malignancie of wounds, the Chirurgeon was not to be blamed, for that it were a crime to fight against God and the Aire, wherein the hidden scourges of the divine justice lye hid. Therefore, if according to the minde of the great Hippocrates, who commands to bring all contused wounds to suppuration, that so they may be healed, wee endeavoured to cure with such medicines wounds made with Gunshot, and therefore contused; who can rightly be angry with us, if we performed it not so well, by reason of these putrefactions, gangreens and mortifications which proceeded from the corrupt Aire, for all that we used not onely suppuratives, but were oft times forced to use other medicines; so long turning aside from the cure of the disease, untill we had overcome the symptoms which much endanger the patient and customarily happen upon such wounds, as also upon those which are made with a sword or any other kind of weapon; As shall plainly appeare in the following treatise, to which it now seemes high time that we betake our selves.

An argument
of great putrefaction of the
humors.

All contused
wounds must
bee brought to
suppuration.

CHAP. I.

A division of wounds drawne from the variety of the wounded parts, and the Bullets which wound.

A division of wounds from the variety of the wounded parts.

From the difference of Bullets.

Wounds made by Gunshot are usually round.

Wounds which are made in mans body by Gunshot, whether simple or compound, are accompanied with contusion, dilaceration, distemper and swelling. I say, all these possesse eyther the noble parts, or ignoble, the fleshy, nervous or bony, some whiles with rending and tearing asunder the larger vessels, sometimes without harming them. Now these wounds are onely superficial, or else peirce deepe and passe quite through the body. But there is also another division of these wounds taken from the variety of the Bullets wherewith they are made. For some bullets are bigger, some lesse, some betweene both, they are usually made of Lead, yet sometimes of Steele, Iron, Brasse, Tinne, scarce any of Silver, much lesse of Gold. There arises no difference from their figure; for almost all kinds of wounds of this nature are round. From these differences, the Chirurgion must take his Indications what to doe, and what medicines to apply. The first care must be, that he thinke not these horrid and maligne symptomes, which usually happen upon these kinds of wounds, to arise from combustion, or poyson carried with the Bullet into the wounded part, and that for these reasons we have formerly handled at large. But rather let him judge they proceede from the vehemencie of the contusion, dilaceration and fracture, caused by the Bullets too violent entry into the nervous and bony bodies. For if at any time the bullet shall onely light upon the fleshy parts, the wounds will be as easily cured, as any other wound usually is, which is made with a contusing and round kind of weapon, as I have often found by frequent experience, whilest I have followed the warres, and performed the part of a Chirurgion to many Noble-men and common Souldiers, according to the counsell of such Physicians as were there overseers of the cure.

CHAP. II.

Of the signes of wounds made by Gunshot.

Signes of wounds from their figure. From their colour. From the feeling the blow.

From the bleeding.

From the heate of the wound.

Wounds made by Gunshot are knowne by their figure, which is usually round; by their colour, as when the native colour of the part decays, and in stead thereof a livid, greenish, violet or other colour succeeds; by the feeling or sense of the stroke, when in the very instant of the receiving thereof, hee feels a heavy sense as if some great stone, or peice of Timber, or some such other weighty thing had fallen upon it; by the small quantity of blood which issues out thereat, for when the parts are contused, within some small while after the stroke they swell up, so that they will scarce admit a Tent, whence it is that the blood is stopped, which otherwise would flow forth of the orifice of the wound; by heate, which happens eyther by the violentnesse of the motion, or the vehement impulsion of the aire, or the attrition of the contused parts, as the flesh and nerves.

Whence these wounds are so much contused.

Also you may conjecture that the wounds have beene made by Gunshot, if the bones shall be broken, and the splinters thereof by pricking the neighbouring bodies cause defluxion and inflammation. But the cause that the Bullet makes so great a contusion is, for that it enters the body not with any points or corners, but with its round and sphericall body, which cannot penetrate but with mighty force; whence it commeth to passe that the wound lookes blacke, and the adjacent parts livid. Hence also proceede so many grievous symptomes, as paine, Defluxion, Inflammation, Apostumation, Convulsion, Phrensie, Palsie, Gangreen and mortification, whence lastly death ensues. Now the wounds doe often cast forth virulent and very much stincking filth, by reason of the great contusion, and the rending and tearing of the neighbouring particles. A great abundance of

of humors flow from the whole body, and fall downe upon the affected parts, which the native heate thereof being diminished forsakes, and presently an unnaturall heate seizes upon it. Hither also tend an universall or particular repletion of ill humours, chiefly if the wounds possesse the nervous parts as the joynts. Verily neither a Stagge with his horne, nor a flint out of a sling can give so great a blow, or make so large a wound, as a Leaden or Iron Bullet shot out of a Gun, as that which going with mighty violence, pierces the body like a Thunderbolt.

CHAP. III.

How these wounds must be ordered at the first dressing.

He wound must forthwith be enlarged, unlesse the condition of the part resist, that so there may be free passage forth both for the *Sanies*, or matter, as also for such things as are forced, or otherwise contained therein; such as are peices of their cloathes, bombast, linnen, paper, peices of Maile or Armour, Bullets, Haile-shot, splinters of bones, bruised flesh and the like, all which must be plucked forth with as much celerity and gentlenesse as may bee. For presently after the receiving of the wound the paine and inflammation are not so great, as they will be within a short time after. This is the principall thing in performance of this worke, that you place the patient just in such a posture as he was in at the receiving of the wound; for otherwise the various motion and turning of the Muscles will eyther hinder or straiten the passage forth of the contained bodies. You shall if it be possible, search for these bodies with your finger, that so you may the more certainly and exactly perceive them. Yet if the Bullet bee entred somewhat deepe in, then you shall search for it with a round and blunt probe, lest you put the patient to paine; yet oftentimes you shall scarce by this meanes finde the Bullet. As it happened to the Marshall of *Brissac* in the seige of *Parpignan*, who was wounded in his right shoulder with a Bullet, which the Chirurgions thought to have entred into the capacitie of his body. But I, wishing the patient to stand just in the same manner as hee did when hee received the wound, found at length the place where the Bullet lay, by gently pressing with my fingers, the parts neare the wound, and the rest which I suspected; as also by the swelling, hardnesse, paine and blacknesse of the part, which was in the lower part of the shoulder neare unto the eight or ninth spondill of the backe. Wherefore the bullet being taken forth by making incision in the place, the wound was quickly healed and the Gentleman recovered. You shall well observe this, and rather beleve the judgement of your fingers, than of your probe.

Strange bodies must first be pulled forth,

The manner how to draw them forth.

CHAP. IIII.

A description of fit Instruments to draw forth Bullets and other strange bodies.

Both the magnitude and figure of Instruments fit for drawing forth of Bullets and other strange bodies, are various according to the diversity of the incident occasions. For some are toothed, others smooth, others of another figure and bignes; of all which sorts the Chirurgion must have divers in a readinesse, that he may fit them to the bodies and wound, and not the wounds and bodies to his Instruments.

The Deliniation of such like Instruments.

A toothed Crowes-Bill.

The

The crooked Cranes-bill, with teeth like a Saw.

The straight Cranes-bill being also toothed, fit for drawing forth haile-shot, pieces of armour, splinters of bones, and such things as lye deepe within.

The Ducks-bill.

This Ducks bill hath a large round and toothed cavities in the end, for so it more easily taketh hold of the Bullet when it lies amongst much Flesh.

Another Instrument fit for drawing forth of Bullets, which may be termed, a Catch-bullet.

A. Shewes the Trunke.

B. Shewes the rod, or string, which opens & shuts the joint.

C. The joint.

Another

Another Catch-bullet called a Lizards-nose, made for drawing out of bullets which are somewhat flattened, by striking upon a bone.

The Parrots-beake is made for drawing forth peices of maile thrust into the flesh, flesh, or bones; and this is the figure thereof.

A. Shewes the screw pin. B. The hollowed part which receives, the round part noted with. C. which is opened and shut by the screw. D. D. falls, or staves, which governe the running branch.

The Swannes bill opens with a screw: you may with this dilate the wounds, and so put in a straight Cranes-bill, as pincers to plucke forth strange bodyes. The figure of both are heere exprest.

But if these strange bodyes, especially bullets and haile shot, be not too deepe in the wound, they may be taken forth with your Levatorie, or else by the helpe of these Gimbets. These Gimbets are screwed into their pipes, or canes, and enter with their screwed points into the Bullets, if that they be of Lead or Tin, and of no harder metall; and so being fastened in them, bring them out with them.

The

The figure of the Gimbles with his pipe, or cane.

Besides the Swanf-bill which wee lately mentioned, there are also other Instruments fit to dilate and open the wounds; therefore called Dilaters, by whose helpe the wound may be held open, that so the hidden bodyes may be seene; for when you presse together the two ends of this Instrument, the other two open and dilate themselves. You may also use them in dilating divers other parts of the body, as the Nose-thrills, fundament, and such like.

Dilaters.

The Instruments which follow are called Seton needles, or Probes; whose use is, to draw through a flamula, so to keepe the wound open, that you may the better take forth any strange body. Besides also we use the same needles, to search, or as it were to sound the deepenesse of wounds, and to finde out the Bullets. For they cannot put one to much paine because they have smooth and round ends. So also all Probes wherewith we search for Bullets, must have somewhat large, smooth and round ends. For seeing that the verges of the wound meete together presently after the hurt, if the Probes be too small or slender, they will sticke in the inequality of the flesh, neither will they be able to come to the Bullet. But if they bee sharpe and pointed, they will cause and renew the paine by pricking the flesh they melt withall, and so hinder your intention of finding the Bullet; Now you must bee furnished with these Instruments of a different length, according to the various thicknesse of the parts; for you cannot put any through the thigh but such as are of good length.

What probes
fit to search
these wounds.

Probes for to put flamulaes through a wound withall.

CHAP. IX.

what dressing must first be used, after the strange bodies are pluckt or drawn out of the wound.

When the strange bodies are drawne or pluckt out of the wound, by these meanes we have formerly recited, the chiefe of the cure must be to heale the contusion, and amend the distemper of the aire if it bee hot and moyst, that is, subject to putrefaction. This shall be don by medicins taken inwardly, applied outwardly and put into the wound. Things to be inwardly used in dyet and Pharmacie I leave to the judgement of learned Physitions; for the particular and to pickie medicines, (unlesse from the present constitution of the ayre, the condition of the wounded part, or from some other cause there be danger of a Gangrene) you must use suppuratives, as you usually doe in contusions; such as are oyle of Whelpes and that which we call a digestive; you must chiefly forbear suppuratives, when as the wounded part is of a nervous nature. For all nervous parts require dryer medicines than fleshy, as we have formerly delivered speaking of wounds of the joynts; wherefore in wounds of the joynts and nervous parts you shall use more venice Turpentine than oyle. *Laurentius Iobertus* the Kings Physition and Chancellour of the Vniversity of Mompelier, in a treatise which hee writ of wounds made with Gunshot, forbids the use of Escharotickes both actuall and potentiall, in these wounds, if simple; for that they induce paine, inflammation, a feaver, Gangrene and other deadly symptomes. Besides also an eschar will hinder suppuration, which is to bee desired in this kinde of woundes, that so the contused flesh may be severed from the sound, least it be drawne to putrefaction by contagion. Which easily happens when an Eschar is drawne, as a barre over it, for then the excrementitious humor remains longer in the part, and the putridinous vapours hindered from passing forth, are increased, and carryed from the lesser vessells to the bigger, and so over all the body. Wherefore, when you suspect putrefaction, letting alone suppuratives, use in the first place such things as resist putrefaction, as this following ointment. *R. pulver. alumin. rocha. viridis aris. Vitrioli romani. mellis rosat. an. ʒij. aceti boni quantum sufficit, bulliant omnia simul secundum artem, & fiat medicamentum ad formam mellis.* This by reason of the heate and subtilty of the substance, hath a faculty to induce and attenuate the humors, as also to call forth the native heate drawne in and dissipated by the violent and forcible entrance of the Bullet into the body; furthermore also it corrects the venemous contagion of the virulent humor. Now this medicine shall be used, dissolved in Venegar or *aqua vita*, and be put into the wound with tents, or pledgets. The tents which shall bee used at the first dressing must be somewhat long and thicke, that by dilating the wound, they may make way for application of other remedies; otherwise you may make injection with a syring, that so it may penetrate the more powerfully. But this described *Egyptiacum* shall be tempered according to the condition of the affected parts, for the nervous parts will bee offended with it as being too acide; but it may be qualified by admixture of oyle of Turpentine and Saint Iohn-wort. Also we may well be without this *Egyptiacum* when there is no such pestilent constitution of the ayre, as was seene in the late Civill warres. After the use of *Egyptiacum* you shall with emollient and lenitive medicines procure the falling away of the Eschar, and such a medicine is this following oyle, being somewhat more than warme.

A Caution in the use of suppuratives.

Why Escharotickes must be eschewed in these kinds, if they be simple.

How an Eschar may cause putrefaction.

The description of an *Egyptiacum*.

How and when to temper this *Egyptiacum*.

The oyle of Whelpes a digestive, anodyne, and fit medicine to procure the falling away of an Eschar.

R. Olei violati lib. iij. in quibus coquantur catelli duo nuper nati, usque ad dissolutionem ossium, addendo vermium terrestrium, ut decet preparatorum. lb. j. coquantur simul lento igne, deinde fiat expressio ad usum, addendo terebinth. venet. ʒij. aqua vita ʒj. This oyle hath a wonderful force to assuage paine, to bring the wound to suppuration, & cause the falling away of the Eschar. This ensuing oyle is made more easily. R. olei seminis lini, & lilior. an. ʒij. unguem. basilic. ʒj. liquefiant simul & fiat medicamentum; put of this a sufficient quality into the wound; for this being applyed indifferent hot, hath power to assuage pain, to soften and hument the orifice of the wound, and help forwards suppuration, which is the true manner of curing these kinde of wounds, according to

Lib. de ulcer.

the rule of *Hippocrates*, which wishes every contused wound to bee presently brought to suppuration, for so it will be lesse subject to a Phlegmon; and besides, all the rent and bruised flesh must putrifie, dissolve and turne to quitture, that new and good flesh may be generated in steed thereof.

The faculties of the powder of Mercury.

Laurentius Ioubertus much commends this following medicine, of whose efficacy, as yet, I have made no triall. *R. pulver. mercur. bis calcinati, ℥j, adipis porci recentis, vel butyri recentis, ℥viij. Camphora in aqua vite dissoluta, ℥ij. misce omnia simul, addendo tantillum olei liliorum, aut lini.* Experience taught him, and reason also shewes, that this kinde of remedy is very commendable; for the powder of Mercury, if mixed with a grosse and humecting matter, doth in a short space turne the bruised flesh into pus, without causing any great paine. For the Camphire, whether it be hot or cold, in temper, it much conduces to that purpose, by reason of the subtilty of the parts, whereof it consists. For by meanes of this quality the medicines enter with more facility into the affected bodyes, and performe their parts; besides also Camphire resists putrification. Some droppe into the wound *aqua vite*, wherein they have dissolved some calcined vitrioll. Which kind of remedy is not suppurative, but yet much resists putrefaction, so that we may use it with good successe, when the weather is hot, moyst, and foggie. But when the wound is made very neere at hand, it cannot but be burnt by the flame of the powder; in which remedies used for burnes, will be usefull, not omitting such as are fit for contusions. But for these parts which lye next the wound, you shall not, unlesse at the first dressing apply, refrigerating and astringent things, but rather emollient and suppurative. For those things which have a refrigerating faculty, weaken the part, and hinder suppuration. For astringents constrict the skin, which is the cause, that the putride vapours shut up and hindered from transpiration and passage forth, a gangrene and mortification easily seaze upon the part. But if the contusion be great and diffuse it selfe more largely over the flesh; the part must be much scarified; that so the contused and concreat blood, and therefore subject to putrefaction, may be evacuated. But for these parts, which somewhat further distant from the wound encompass the contused flesh, they require refrigerating and strengthening medicines, so to hinder the falling downe and setting of the humor in that part; such is this ensuing medicine. *R. Pul. boli. armen. sanguin. Dracon. Myrrha. an. ℥j succi solan. semper vivi, portulac. an. ℥iss. album iij. ovorum. exyrhodin. quantum sufficit; fiat linimentum, ut decet.* You may use this, and the like untill the suspected symptome, be past feare. Neither must you have lesse care, of binding up and rolling the part, than of your medicines; for it doth not a little conduce to the cure, to binde it so fittly up as it may be without paine. The wound at the beginning of the cure, must be dressed but once in 24. houres, that is, untill the wound come to suppuration; but when the quitture begins to flow from it, and consequently the paine and feaver are encreased, it shall be drest twise a day, that is every twelve houres. And when the quitture flowes more abundantly than usuall, so that the collection thereof is very troublesome to the Patient, it will be requisite to dresse it every 8 houres; that is thrise a day. Now when as this abundant effluxe is somewhat flaked, and begins to decrease, it will suffice to dresse it twise a day. But when the ulcer is filled with flesh, and consequently casts forth but little matter, it will serve to dresse it once a day, as you did at the first.

The force of calcined vitrioll.

How wounds made by Gunshot may be combut.

Scarification.

An Astringent repelling medicine.

The binding up.

How oft the wound must be drest in a day.

CHAP. VI.

How you shall order it at the second dressing.

The second and following dressings, unlesse you suspect putrification, and a Gangrene, you shall onely put into the wound some of the oyles formerly described, adding to them the yolkes of some egges and a little saffron; and use this medicine, untill the wound come to perfect suppuration. Here you must note this, that these kindes of wounds are longer before they come to suppuration, than other wounds made by any other sort of weapon; both for that the bullet, as also the ayre which it violently carries before it, by much bruising the flesh, on every side, dissipates the native heate, and exhausts the spirits of the part. Which things hinder

Why wounds made by Gunshot are so long before they come to suppuration.

hinder digestion, and often cause the matter to stinke, as also many other pernicious symptoms. Yet most usually pus or quittance appeares within three or foure dayes, sooner and later according to the various complexion, and temperament of the patients bodies, and the condition of the ambient ayre in heate and cold. Then by little and little you must come to deterfives, adding to the former medicine some Turpentine washed in Rose, Barly, or some other such like water, which may wash away the biring thereof. If the encompassing ayre be very cold, you may to good purpose adde some *aqua vita*; for by *Galens* prescript, we must use hot medicines in winter, and lesse hot in summer. Then in the next place use deterfives, as *R. aqua decoctionis hordei quantum sufficit, succi plantaginis, appj, agrimon. centauri minoris, an. ʒj, bulliant omnia simul; in fine decoctionis adde terebinthina veneta ʒiij. mellis rosat. ʒij. farin. hordei. ʒiij. croci ʒj.* Let them be all well mixed together and make a Mundificative of an indifferent consistence. Or *R. succi clymeni, plantag. absinth. appj, an. ʒij. tereb. venet. ʒ4. syrup. absinth. & mellis ros. an. ʒij. bulliant omnia secundum artem, postea colentur, in colatura adde pulver. aloes, mastiches, Treos Florent. far. bord. an. ʒj. fiat Mundificativum ad usum dictum.* Or else *R. terebinth. venet. lota in aq. ros. ʒv. olei ros. ʒj. mellis ros. ʒiij. myrrha, aloes, mastich. aristoloch. rotunde, an. ʒiij. far. bord. ʒiij. misce.* Make a Mundificative, which you may put into the wound with tents, but such as are neither too long, nor thicke, lest they hinder the evacuation of the quittance and vapours, whence the wounded part will bee troubled with erosion, paine, defluxion, inflammation, absesse, putrefaction; all which severally of themselves, as also by infecting the noble parts, are troublesome both to the part affected, as also to the whole body besides. Wherefore you shall put into the wound no tents, unlesse small ones, and of an indifferent consistence; lest (as I sayd) you hinder the passing forth of the matter, or by their hard pressing of the part, cause paine, and so draw on malignant symptoms. But seeing tents are used both to keepe open a wound so long, untill all the strange bodies be taken forth, as also to carry the medicines, wherewithall they are annointed: even to the bottome of the wound. Now if the wound be sinuous and deepe, that so the medicine cannot by that meanes arrive at the bottome and all the parts thereof, you must doe you business by injections made of the following decoction. *R. aq. bord. lib. 4. agrimon. centaur. minor. pimpinelle, absinth. plantag. an. M. ʒ. rad. aristoloch. rotund. ʒʒ. fiat decoctio ad lib. j. in colatura expressa dissolve aloes hepatica ʒiij. mellis ros. ʒij. bulliant modicum.* Inject some of this decoction, three or foure times into the wound, as often as you dresse the patient; and if this shall not be sufficient to cleanse the fith, and waste the spongius, putride and dead flesh, you shall dissolve therein as much *Egyptiacum* as you shall thinke fit for the present necessity; but commonly you shall dissolve an ounce of *Egyptiacum* in a pint of the decoction. Verily *Egyptiacum* doth powerfully consume the proud flesh which lyes in the capacity of the wound; besides also it only workes upon such kind of flesh. For this purpose, I have also made triall of the powder of Mercury, and burnt Alome equally mixed together, and found them very powerfull, even almost as sublimate, or Arsenicke, (but that these cause not such paine in their operation.) I certainly much wonder at the largeness of the Eschar which arises by the aspersio of these powders. Many Practitioners would have a great quantity of the injection to be left in the cavities of sinuous ulcers, or wounds; which thing I could never allow of. For this contained humor causeth an unnaturall tension in these parts, and taints them with superfluous moisture, whereby the regeneration of flesh is hindered; for that every ulcer as it is an ulcer, requires to be dried, in *Hippocrates* opinion. Many also offend in the too frequent use of Tents; for as they change the every houre, they touch the sides of the wound, cause paine, & renew other malignant symptoms; wherefore such ulcers as cast forth more abundance of matter, I could wish rather to be dressed with hollow tents, like those I formerly described to be put into wounds of the Chest. You shall also presse a linnen boulder to the bottome of the wound, that so the parts themselves may be mutually condensed by that pressure and the quittance thrust forth; neither will it be amisse to let this boulder have a large hole fitted to the orifice of the wound & end of the hollow tent and pipe, that so you may apply a sponge for to receive the quittance, for so the matter will be more speedily

Why Turpentine must be washed,

The manner of binding up the wound.

evacuated and spent, especially if it be bound up with an expulsive ligature, beginning at the bottome of the ulcer, and so wrapping it up to the toppe. All the boulders and rowlers, which shall be applyed to these kindes of wounds, shall be dipped in Oxycrate, or red wine, so to strengthen the part, and hinder defluxion. But you must have a speciall care, that you doe not binde the wound too hard, for hence will arise paine, hindring the passage forth of the putredinous vapours and excrements, which the contused flesh casts forth; and also feare of an *Atrophie*, or want of nourishment, the alimentary juyces being hindred from comming to the part.

CHAP. VII.

By what meanes strange bodyes, left in at the first dressing, may be drawne forth.

Two causes
that make
strange bodies
hard to be taken
forth.

IF divers times happens, that certaine splinters of bones, broken and shattered asunder by the violence of the stroake, cannot be pulled forth at the first dressing, for that they either doe not yeeld or fall away, or else cannot be found by the formerly described instruments. For which purpose this is an approved medicine to draw forth that which is left behind.

R. *radic. CHAP. VIII.

Of Indications to be observed in this kinde of wounds.

THE ulcer being clensed and purged, and all strange bodyes taken forth; nature endeavours to regenerate flesh, and cicatrize it, must be helped forwards with convenient remedies, both taken inwardly, and applyed outwardly. To which things we may be easily and safely carryed by indications drawne, first from the essence of the disease, then from the cause; if as yet present it nourish the disease. For that which *Galen* sayes, *Lib. 3. Meth.* that no indication may be taken from the primitive cause and time; must be understood of the time past, and the cause which is absent. And then from the principall times of the disease, the beginning, encrease, state, and declination; for each of these foure require their remedies. Others are taken from the temperament of the patient, so that no Chirurgeon neede doubt, that some medicines are fit for cholericke, other some for phlegmaticke bodyes. Hither referre the indication taken from the age of the patient; also it is drawn from his dyet, for no man must prescribe any slender diet to one who is alwayes feeding, as to him who is accustomed to eate but once, or twice a day. Hence it is that a dyet consisting onely of *Panada's* is more fit for Italians, than for French men; for we must give somewhat to custome, which is as it were another nature. Vocations and dayly exercises, are referred to dyet, for other things besit husbandmen and labourers, whose flesh is dense and skin hardened by much labour, than idle and delicate persons. But of all other, have diligent regard of that indication which is drawne from the strength of the patient; for we must presently, (all else being neglected) succour the fainting, or decaying strength; wherefore if it be needfull to cut off a member that is putrified, the operation must be deferred if the strength of the patient be so dejected, that hee cannot have it performed without manifest danger of his life. Also indication may be drawne from the encompassing ayre, under which also is comprehended that, which is taken from the season of the yeere, region, the state of the ayre and soyle, and the particular condition of the present and lately by-past time. Hence it is we read in *Guido*, that wounds of the head are cured with

The Indication

the strength
of the patient
is the chiefest
of all other.

with farre more difficulty at *Paris*, than at *Avignon*; where notwithstanding on the contrary, the wounds of the legges are cured with more trouble, than at *Paris*; The cause is, the ayre is cold and moyst at *Paris*; which constitution seeing it is hurtfull to the braine and head, it cannot, but must be offensive to the wounds of these parts. But the heate of the ambient ayre at *Avignon*, attenuates and dissolves the humors, and makes them flow from above downewards. But if any object that experience contradicts this opinion of *Guido*, & say, that wounds of the head are more frequently deadly in hot countries; let him understand that this must not be attributed to the manifest & naturall heate of the ayre, but to a certaine maligne & venenate humor, or vapour disperfed through the ayre, and rayfed out of the Seas; as you may easily observe in those places of France & Italy which border upon the Mediterranean Sea. An indication may also be drawne from the peculiar temper of the wounded parts, for the musculous parts must be dressed after one, and the bony parts after another manner. The different sense of the parts, indicates and requires the like variety of remedies; for you shall not apply so acride medicines to the Nerves and Tendons, as to the ligaments which are destitute of sense. The like reason also, for the dignity and function of the parts needfull for the preservation of life; for oft times wounds of the braine, or of some other of the naturall and vitall parts, for this very reason that they are desired in these parts, divert the whole manner of the cure, which is usually and generally performed in wounds. Neither that without good cause, for oft times from the condition of the parts, we may certainly pronounce the whole successe of the disease; for wounds which penetrate into the ventricles of the braine, into the heart, the large vessels, the chest, the nervous part of the midriffe, the Liver, ventricle, small guts, bladder, if somewhat large are deadly; as also these which light upon a joynt in a body replete with ill humors, as we have formerly noted. Neither must you neglect that indication which is drawne from the situation of the part, and the commerce it hath with the adjacent parts, or from the figure thereof; seeing that *Galen* himselfe would not have it neglected. But wee must consider in taking these forementioned Indications, whether there bee a composition, or complication of the diseases; for as there is one and that a simple indication, of one & that a simple disease, so must the indication be various of a compound and complicate disease. But there is observed to be a triple composition, or complication of affects besides nature; for either a disease is compounded with a disease, as a wound, or a pblegmon with a fracture of a bone; or a disease with a cause, as an ulcer with a defluxion; or a disease with a symptome, as a wound with paine, or bleeding. It sometimes comes to passe, that these three, the disease, cause, and symptome, concur in one case or affect. In artificially handling of which, we must follow *Galens* counsell, who wises in complicated and compounded affects, that we resist the more urgent; then let us withstand the cause of the disease, and lastly that affect, without which the rest cannot be cured. Which counsell must well be observed; for in this composure of affects, which distracts the Empericke; But on the contrary the rationall Physition hath a way prescribed in a few and these excellent words, which if hee follow in his order of cure, hee can scarce misse to heale the patient. Symptomes truly as they are symptomes, yeeld no indication of curing, neither change the order of the cure; for when the disease is healed, the symptome vanishes, as that which followes the disease, as a shadow followes the body. But symptomes doe often times so urge and presse, that perverting the whole order of the cure, we are forced to resist them in the first place, as those which would otherwise encrease the disease. Now all the formerly mentioned indications may be drawne to two heads; the first is, to restore the part to its native temper; the other is that the blood offend not either in quantity or quality; for when these two are present, there is nothing which may hinder the repletion, nor union of wounds or Vlcers.

Why wounds of the head at *Paris*, and of the legges at *Avignon* are hard to be cured.

An indication to be drawne from the quicke and dullente of the wounded parts.

An Anodyne
and ripening
Cataplasme

He Chirurgion must first of all be skilfull and labour to assuage paine, hinder defluxions, prescribe a dyet in these sixe things we call Not naturall, forbidding the use of hot and acrid things, as also of wine; for such attenuate the humors and make them more apt for defluxion. Therefore at the first let his dyet be slender, that so the course of the humors may bee diverted from the affected part; for the stomacke being empty and not well filled, drawes from the parts about it, whereby it consequently followes, that the utmost and remotest parts are at the length evacuated; which is the cause, that such as are wounded, must keepe so spare a dyet for the next dayes following. Venery is very pernicious, for that it inflames the spirits and humors farre beyond other motions; whereby it happens that the humors waxing hot, are too plentifully carryed to the wounded and overheated part. The bleeding must not bee stanchd presently upon the receiving of the wound, for by the more plentiful efflux thereof the part is freed from danger of inflammation and fulnesse. Wherefore if the wound bleede not sufficiently at the first, you shall the next day open a veine, and take blood according to the strength and plenitude of the patient; for there usually flowes no great store of blood from wounds of this nature; for that by the greatnesse of the contusion and vehemencie of the mooved ayre, the spirits are forced in, as also I have observed in those who have one of their limbes taken away with a Cannon bullet. For in the time when the wound is received, there flowes no great quantity of blood, although there be large veines and arteries torne in sunder thereby. But on the 4, 5, 6. or some more dayes after, the blood flowes in greater abundance, and with more violence, the native heate and spirits returning into the part. The belly must be so qualified, that he may have at the least one stoole a day, either by nature, or Art; and if by Art, then rather with a glister than purging medicines taken by the mouth, for that the agitation of humors, chiefly in the first dayes of the disease, is to be suspected, least we increase the defluxion falling downe upon the wounded part. Yet Galen writes that both the evacuations are heere needefull, that is, blood-letting and purging, though the Patient bee neither phethoricke, nor replete with ill humors. But the care hereof must be committed to the judgement of the learned Physition. Paine if ioyned with inflammation shall be mitigated, by anointing the parts neere unto the wound with *Vnguent. nutritum*, composed with the juyce of Plantaine, Houslecke, Nightshade and the like. *Vnguentum Diacalcis theos* described by Galen dissolved with vinegar, oyle of Poppyes and Roses is of no lesse efficacy; nor *unguent. de bolo*, nor divers other things of the same faculty, though properly no anodynes, as those which are not hot and moyst in the first degree, but rather cold, but yet not so as to have any narcoticke faculty. Now these forementioned things assuage paine for that they correct the hot distemper, and stay the acride and cholericke defluxions, whose violence is more than cold. After the use of repercussives, it will be good to apply this following cataplasme. *R Mica panis infusa in lacte vaccino lb. j. β. bulliant parum addendo olei violacei, & rosar. an. ℥iij. vitellos ovorum nn. iiij. pulver. rosar. rub. flor. chamem. & meliloti, an. ℥ij. farin. fabar. & bordei, an. ℥j. misce, fiat cataplasma secundum artem.* Also in this case you may easily make a medicine, of bread crummes boyled in Oxycrate and oyle of Roses. The cure of Tumors, if any associate the wound, may be found in their proper place. Natures motion, whether to suppuration, or any such thing, must still be observed, and helped by the Physition and Chirurgion, as the ministers or servants thereof.

CHAP. X.

Of Bullets which remaine in the body, for a long time after the wound is healed up.

LEaden Bullets lye in some parts of the body some whiles leaven, eight or more yeares, so that they neither hinder the agglutination of the wound, neither doth any other symptome happen thereupon, as I have diverse times observed; untill at length by the strength of nature forcing them, and their proper weightines bearing them downewards, they shew themselves in some lower part, by their swelling or bunching forth, and so must be taken forth by the hand of the Chirurgion. For they say Lead hath a certaine sympathy and familiarity with mans body, chiefly the fleshy parts thereof. Wherefore it neither putrifies its selfe, nor causeth the flesh to putrifie; besides it hath an excellent faculty in cicatrizing old ulcers. But bullets of stone, Iron and of any other mettrall, are of another nature, for they cannot remaine any long time in the body without hurt; for Iron will grow rusty, and so corrode the neighbouring bodyes, and bring other malignant symptomes. Yet a Leaden bullet cannot remaine any long time in nervous, or noble parts without danger.

Why Leaden Bullets lye in the body so many yeeres without doing any harme.

CHAP. XI.

How to correct the constitution of the ayre, so that the noble parts may be strengthened, and the whole body besides.

BUt because as we have formerly told you, there are some times wherein even small wounds made by Gunshot prove deadly, not by their owne fault, but the fault of the ayre; therefore also the Chirurgion must have this care, that he correct the ayre with all diligence, and reduce it to a certaine quality and moderation of substance, and strengthen the noble parts and whole body besides, which may be performed, by the following medicines, which are to be taken inwardly and applied outwardly. In the morning three houres before meate let the Patient take some certaine quantity as the Physicion shall thinke fit of the electuary *Diarrhodon Abbat*, or *Aromaticum rosatum*, *irrasantalon*, *biamoschum*, *latificans Galeni*, or some such other like. And you shall apply some such Epitheme as is heere described to the heart and Liver. *R. aque rosar. ℥iiij, aqua buglossa, aceti boni, an. ℥ij. coriandri preparati ℥ss. caryophyll. cortic. citri, an. ℥j. sant. rub. ℥ss. ceralli utriusque ℥ss. camphora ℥j. croci ℥ss. pulver. diarrhod. Abbat. ℥ij. theriaca & Adithridatij an. ℥ss. pul. flo. chamem & melis. an. ℥iiij. misce, fiat epithema.* Let it be applyed warme by dipping a scarlet cloath therein. You shall frequently put odoriferous and refrigerating things to the patients nose, to strengthen the animall faculty, as, *R. aqua rosar. & aceti boni. an. ℥iiij. caryophyllorum, nucus moschat, cinamomi conquassatorum, & Theriaca Galeni, an. ℥j.* Let a linnen ragge dipped herein, be now and then put to the patients nose; for the same purpose he shall carry a Pomander about him, and often smell thereto. *As R. ros. rub. violar. an. ℥iiij. baccarum myrti, juniperi, santal. rub. an. ℥iiij. styracis calamit. ℥ij. aq. rosarum, quantum satis est: lique fiat simul cum cera alba quod sufficit, fiat ceratum ad comprehendendos supradictos pulvers cum pistillo calido, & ducatur in pomum.* Or *R. rad. Ireos Florent. majoran. calam. aromat. ladanij, benzoini, rad. cyperi, caryophyll. an. ℥j. Moschi. gra. 4. fiat pulvis cum gummi tragacanth. quod sufficit.* Or else *R. ladanij puri ℥i. Benzoini ℥ss. styracis calamit. ℥j. Ireos Flor. ℥ss. caryophyll. ℥iiij. majoran. ros. rub. calam. aromat. an. ℥ss, in pollinem redigantur omnia, & bulliant cum aqua ros. quantum sufficit; colentur, colata liquefiant cum justa cera alba quantitate, styracis liquide, ℥j, fiat ad modum cerati, & cum pistillo fiat pomum, addita moschi ℥j.* Also you may corroborate the animall faculty by application of frontalls, as also procure sleepe, and ease the paine of the head;

Cordials to strengthen the noble parts.

A cordiall Epithem.

Pomanders.

Frontalls to cause rest, and strengthen the animall faculty.

as,

A sweete was-
ter.Perfume to
burne.

as, R. *aq. ros.* ℥ij. *olei ros.* & *papav. an.* ℥i℥. *aceti boni*, ℥j. *trochis. de camphora*, ℥℥. *fiat frons- tale*. Linnen ragges dipped herein may be applyed to the temples of the forehead, and often renewed; otherwise by their heate, drynesse, and hardnesse, they will cause watching in steed of sleepe. Neither must you in the meane time binde the head too hard, lest by intercepting and hindring the pulsation of the temporall Artery, you encrease the paine of the head. You shall make a fire, in the patients chamber of orderiferous woods, as Juniper, Bay-tree, the prunings or cuttings of Vines, Rosemary, and Orris rootes. For the same purpose, you may sprinkle the floore with sweete water, if the patient be able to undergoe such cost. As, R. *majorana, mentha, radic. cyperi, calami aromat. salvia, lavendula, fanicul. thymi, stachad. flor. chamam. melilot. saturcia, baccarum lanri, & juniperi, an.* M. iij. *pulv. caryophyll. nucis Moschat. an.* ℥j. *aqua rosar. & vite, an. lib. ij. vini albi boni & odorifici. lb. x. bulliant omnia in balneo Maria ad usum dictum*. You may also make perfumes to burne in his chamber, as thus, R. *carbonis salcis* ℥viiij. *ladani puri* ℥ij. *thuris masculi, ligni & baccarum Juniperi, an.* ℥j. *xyloaloes, benjoini, styracis calami, an.* ℥℥. *Nucis moschatae, Jantab. citrin. an.* ℥iij. *caryophyll. styracis liquida, an.* ℥ij. *zedoaria, calami aromat. an.* ℥j. *gummi tragacanth. aqua rosar. soluti, quod sit satis*; Make hereof perfumes in what fashion you please. For the rottennesse and corruption of bones we will treat thereof hereafter in its due place.

CHAP. XII.

Certaine memorable Histories.

The malignant
symptomes
which usually
happens upon
wounds made
by Gunshot.Matter may
flow from the
wounded
limbes into the
belly.

Ere I thinke good for the benefit of young practitioners, to illustrate by examples the formerly prescribed Methode of curing wounds made by Gunshot. The famous and most valiant Count of Mansfelt, Governour of the Dutchy of *Luxembourge*, Knight of the order of Burgundy, comming to the ayde of the French King, was at the battell of Moncontour, where in the conflict, he received so great a wound at the joynt of the left arme with a Pistoll bullet, that the bones were shivered and broken in to many peeces, as if they had bin layd upon an Anvill and struck with an hammer: hence proceeded many malignant symptomes, as cruel & tormenting paine, inflammation, a seaver, an cedematous and flatulent tumor of the whole arme even to the fingers end, and a certaine inclination to a Gangrene: which to resist, *Nicolas Lambert*, & *Richard Hubert* the Kings Chirurgions, had made many and deepe scarifications. But when I came to visite and dresse him, by the Kings appointment, and had observed the great stinch, and putrefaction, I wished that they would use lotions of *Aegyptiacum* made somewhat stronger than ordinary, & dissolved in venegar & *aqua vite*, and do other things more largely spoken of in the chapter of a Gangrene. For the patient had also a *Diarrhea* or fluxe, whereby he evacuated the purulent, and stinking filth which flowed from his wound. Which how it might come to passe wee will show at large when we come to treat of the suppression of the Vrine. For this seemed very absurd to many, because that if this purulent humor flowed out of the arme into the belly, it must needs flow backe into the veines, bee mixed with the blood, and by its pernicious and contagious passage through the heart and liver, cause exceeding ill symptomes, and lastly death. Indeed he often swounded by the ascent of the filthy vapours raised from the ulcers to the noble parts; which to resist, I wished him to take a spoonefull of *aqua vite* with some Treacle dissolved therein. I endeavoured to repress the cedematous and flatulent Tumor possessing all the arme with stoups dipped in oxycrate, to which was put a little salt and *aqua vite*; these stoups I stayed & held to the part with double clothes, sowed as strait as I could. Such a compression held the broken bones in their places, pressed their *Sanies* from the ulcers, and forced backe the humors flowing to the part into the center of the body. If at any time I omitted this compression, the tumor was so encreased, that I was in a great deal of feare, lest the native heate of the part should bee suffocated. Neither could I otherwise binde up the arme by reason of the excessive paine which molested the patient upon the least stirring of the Arme. There were also many Abscesses about

about his elbow and over all his arme besides. For the letting forth of whole matter I was forced, to make new incisions; which he endured very stoutly. At length I cured him with using a vulnerary potion, and by cleansing the ulcers, and correcting the putrifaction with *Egyptiacum* dissolved in wine or honey of roses, and so poured into the ulcers, and repressing the growth of proud flesh, with the powder of burnt Alome, drying it after the deterfion with liniments. Now this I can truly affirme and professe, that during the time of the cure, I tooke out above threescore splinters of bones, and those necessarily, amongst which there was one of the length of ones finger; yet by Gods assistance at length he became sound in all things, but that hee could not put forth, or draw in his arme.

A breefe recitall of the manner of the cure,

Not long after by the Kings command I went to see *Charles Philip* of Croy, Lord of Aurret, the Duke of Aschos brother, nor farre from Mounts a City of Henalt. He kept his bed seaven monthes by reason of a wound made by a Bullet the space of three fingers above his knee. When I came to him, hee was afflicted with these symptomes, intollerable paine, a continuall feaver, cold sweats, watchings, excoriation of the hippes by reason of his long lying upon them, his appetite dejected with much thirst. He oft sunke downe as if he had the falling sicknesse, had a desire to vomit, and a continuall trembling or shaking so that he could not put one hand to his mouth without the assistance of the other: he swounded frequently by reason of the vapours ascending to the noble parts. For the thigh bone was broken long wayes and sidewayes with many splinters of bones, whereof some were plucked out and others remained sticking fast in. He besides also had an ulcer in his groine which reached to the midst of his thigh, and many other sinuous ulcers about his knee. All the muscles of his thigh and legge were swolne with a flegmaticke, cold and flatulent humor, so that almost all the native heate of those parts seemed extinct. All which things being considered, I had scarce any hope to recover him, so that I repented my comming thither. Yet at length putting some confidence in his strength, and prime of youth, I began to have better hopes. Therefore with his good liking, first of all I make two incisions, so to let forth the matter, which lying about the bone did humect the substance of the muscles. This had happy successe, and drew out a great quantity of matter; then I with a syring injected much *Egyptiacum* dissolved in wine, and a little *aqua vita* into these incisions, so to restraine and amend the putrifaction, repress the spongie, loose and soft flesh, resolve the cedematous and flatulent tumor, assuage the paine, and stirre up and strengthen the native heate almost opprest by the abundance of excrementitious humors, so that it could scarcely assimilate any nourishment and adjoyne it to the parts. Then I fomented the affected part with Sage, Rose-mary, Time, Lavander, Chamomile and Melilot flowres and red-rose leaves boyled in white wine, and lye made of Oake-ashes, adding thereto as much salt and vineger as I judged requisite. This fomentation did attenuate and draw forth the morbidicke humour. Now we used them long and often, so to waste the humour more by drying up and breathing thorow the passages of the skinne, more thereof than fell into the part. For this same purpose, we ordained that he should use frictions with hot linnen clothes, and that these should be made from above downwards, from below upwards, and so on every side, and somewhat long withall: For a short friction drawes more humour into the part than it can resolve: I wished that each other day they should lay bricks heated hot in the fire about his leg, thigh, & soale of his foot; but they were to be somewhat quenched, & sprinkeld with wine and vineger, with a small quantity of *aqua vita*. Much watrish moisture by this moist heat, did sweat out of these parts, the tumour was lessened, and the native heat by little and little restored. Then shoupes dipped in lye made of Oake-ashes, wherein Sage, Rosmarie, Lavender, salt, and cloves, were boyled, some *aqua vita* added, were applyed thereto; but the rowlers were so gently, and artificially wrapped about, that he did easily endure them without any paine, and that with such happy successe, that if they were omitted but for one day, the tumor became very great. But thicke linnen bouldsters were layd upon the lower cavities of the ulcers, that so the sanies or filth might be more easily pressed forth. But I had alwayes a speciall care that the orifices of the ulcers should be kept open with hollow Tents or pipes put therein:

Horride symptomes occasioned by a wound made by Gunshot.

Incisions wherefore made,

Wherefore I used fomentations,

Mixed or round frictions, as they terme them,

A modicated Lye.

and

A discussing
Cataplasme.

and sometimes this following cataplasme was applyed to resolve the tumor. *R. Far. bord. fabar. & orobi, an. ʒvj. mellis com. & tereb. an. ʒij. flo. chamam. melil. & ros. rub. an. ʒß. pulv. rad. Ireos, Flor. cyper. Mast. an. ʒij. oxymel. simp. quantum sufficit; fiat cataplasma ad formam pultis satis liquida.* And *Emplastrum de Vigo* without mercury was applyed thereto, whereby the paine was much asswaged, and the tumor lessened: yet were they not applyed before the parts were throughly heated by the fomentation, frictions, and evaporations; for otherwayes this Emplaster could never have beene activated, by reason of the excessive coldnesse of the affected parts. Neither did we omit catagmaticke powders, fit for the taking, and drawing forth of broken bones. He used a vulnerary potion for 15, dayes. Also besides the particular frictions of the affected parts, I appointed other generall frictions of the whole body, which was become very leane; for by these, blood together with the spirit was drawne to the parts, and the acride, and fuliginous vapours were breathed forth.

To conclude, his feaver and paines being asswaged, his appetite restored, by feeding plentifully upon good meates according to his strength, he in a short time became more lusty; and lastly by the singular mercy of God, recovered his health perfectly, but that he could not very well bend his knee. I thought good to recite these things, not to glory or bragge of the happy successe of those patients, which have recovered by my meanes, and the favour of God; but that thus I may more fully and perfectly by familiar examples instruct young practitioners in the operations of Chirurgery.

CHAP. XIII.

An Apologic concerning Wounds made by Gunshot.

The occasion
of writing
this Apologic.

The chiefe
heads of our
adversaries
Treatise.

All wounds
made by Gun-
shot are con-
tused.

Here lately came to my hands a booke written by a certaine Physicion; whereby he endeavours to disprove and overthrow, that which I have hitherto writ, of the cure of wounds made by Gunshot. Assuredly if there were no other harme, but the losse of my credit ensuing thereon, I would willingly hold my peace, and stoppe his mouth by modest silence. But seeing the safety of so many men, lyes upon the judgement of this point, I have thought good to withstand this error, least it, to the great destruction of mankind, spread and diffule it selfe any further. The use (saith he) of suppurative medicines, have killed many who have beene but lightly wounded with Gunshot, but acride medicines, as *Egyptiacum* have killed more. Neither is the counsell of *Hippocrates* to be observed in curing this sort of wounds, who bids that every contused wound be brought to suppuration. For seeing this is a new kinde of wound, it requires new, and not anciently used medicines. Now the temper of the ayre changed from the naturall constitution ought not to indicate change of medicines; but much lesse must thunder and lightening bee compared to the shooting of Great Ordinance. These are the chiefe heads of this his booke, which because they dissent from the truth, & these things I have formerly delivered, I have thought good heere to confute. First, seeing Leaden bullets which are usually shot out of Guns are round, obtuse and weighty, they cannot wound the body without contusion and attrition; Now no contusion can be cured without suppuration, not onely according to the opinion of *Hippocrates*, but also of *Galen* and all others who have written of Physicke. Neither must we invent new remedies, for these new kindes of wounds; for the lawes of the sacred and divine Art of Physicke are nor obnoxious to change, nor subject to the humor of men or times, as the decrees of Kings and Emperours are. For these are stablished with immutable necessitie, which constancie neither consuming time, nor age, nor tyranny can pervert. Wherefore neither these who with great prayse are Physicions to Kings and Princes, I meane *Ioubert* and *Botallus*, think it lawfull for them to depart from the rule of *Hippocrates*. And this they not onely doe and follow in curing and doing the workes of Art, but much and highly commend, confirme and propound to be diligently observed by all, in their bookes which they

they have published concerning the cure of these kinds of wounds. And yet these Physicians are such, as daily conversant in Armies and Kings houses have healed and daily cure as many wounded by Gunshot as this Physician our Antagonist hath seene in all his life. Neither onely doe these whom I have named thus cure these wounds, but almost all that dresse such kind of wounds doe the like, so that if there bee nothing which may hinder, or indicate to the contrarie they presently apply suppuratives. And I wonder that hee hath not observed how his neighbour *Doublet* the Empericke cures desperate wounds of this nature, with no other than a suppurative medicine, composed of Lard, the yolke of an Egge, Turpentine and a little Saffron.

A suppurative
medicine of
tryed efficacy.

In the year 1538. There was at *Turin* whilest I was Chirurgion there to the Marshall of *Montjan* the Kings Lieutenent Generall in *Piemont*, a certaine Chirurgion wondrous famous for curing these wounds, and yet hee used nothing else but the oyle of Whelpes, (the description whereof I at length obtained of him with much intreaty and expence) and hee used it not scalding hot, as some have imagined, but powred it scarce warme into their wounds, and so did mitigate their paine, and happily bring them to suppuration. Which afterwards almost all Chirurgions, after they had got the description heereof, when I first published this Worke, have used and daily doe use with happy successe.

But in condemning and condemning *Aegyptiacum*, I thinke hee hath no partaker, seeing there as yet hath beene found no medicine more speedy and powerfull to hinder putrefaction, if beginning; or correct it if present. Now these wounds often degenerate into virulent, eating, spreading, and maligne ulcers, which cast forth a stinking and carion-like filth, whence the part Gangrenates, unlesse you withstand them with *Aegyptiacum* and other acrid medicines, being greatly approved by the formerly named Physicians and all Chirurgions. But (saith hee) this unguent is poysonous, and therefore hath beene the death of many who have beene wounded by Gunshot. Verily if any diligently enquire into the composition of this ointment, and consider the nature of all and every the ingredients thereof, hee shall understand that this kind of Vnguent is so farre from poyson, that on the contrary it directly opposes and resists all poyson and putrefaction which may happen to a fleshy part, through occasion of any wound.

The force of
Aegyptiacum
a violent putrefaction.

It is most false and dissonant from the doctrine of *Hippocrates* to affirme, that the seasons of the year swerving from the Law of nature, and the aire, not truly the simple and elementary, but that which is defiled and polluted by the various mixture of putrid and pestilent vapours, cyther raised from the earth, or sent from above, make not wounds more maligne and hard to cure at sometimes than they are at other some.

The force of
the ayre in
breeding and
augmenting
diseases.

For the ayre cyther very hot, or cold, drawne into the body by inspiration or transpiration, generates a condition in us like its qualities. Therefore why may it not, when defiled with the putredinous vapours of bodies lying unburied after great battailes, and shipwracks of great Armadoes, infect with the like qualitie our bodies and wounds?

In the year 1562. when the civill warres concerning Religion first begun in France, at *Pene* a Castle lying upon the River *Lot*, many slaine bodies were cast into a Well, some hundred Cubits deepe, so stinking and pestilent a vapour arose from hence some two moneths after, that many thousand of people dyed all over the Province of *Aginois*, as if the Plague had beene amongst them, the pernicious contagion being spread twenty miles in compasse; which none ought to thinke strange, especially seeing the putride exhalations by the force of the windes may be driven and carried into divers and most remote regions, dispersed like the seeds of the Pestilence; whence proceeds a deadly corruption of the spirits, humors and wounds, not to be attributed to the proper malignitie, or perverse cure of wounds, but to be the fault of the aire.

A History.

Therefore *Francis Daleschampe* in his French Chirurgery, in reckoning up these things which hinder the healing of Vicers, hath not omitted

*Hip. Aph. I.
sect. 3.*

that common cause which proceeds from the ayre defiled or tainted with the seedes of the pestilence. For he had learnt from his Master *Hippocrates* that the mutations of times chiefly bring diseases, and he had read in *Guido*, that this was the chiefe occasion, that wounds of the head at *Paris*, and of the legges at *Avignon*, were more difficultly healed. Lastly even Barbers and such as have least skill in Chirurgery know, that wounds easily turne into a Gangrene in hot and moyst constitutions of the ayre.

In our second
discourse.

The power of
the starres up-
on the Ayre
and our bod-
ies.

*Aph. 20.
sect. 3.*

Wherefore when the winde is southerly, the Butchers will kill no more flesh than to serve them for one day. I have formerly declared the malignity of the wounds occasioned by the ayre in the seige of *Rouen*, which spared none, no not the Princes of the blood, who had all things which were requisite for their health. Which caused me, made at length more skilfull by experience, to use *Unguentum Aegyptiacum* and medicines of the like faculty in steed of suppuratives, to wounds during all that season, that so I might withstand the putrefaction and Gangrene which so commonly assailed them. But if the various motion of the starres, can by their influx send a Plague into the aire, why then may it not by depravation of their qualities infect, and as by poisoning corrupt both wounds and wounded bodies obnoxious to their changes and that of the ayre? Wee learnt long since by experience, that all paines but principally of wounds, grow worse in a rainy and moist season, specially because in that southerly constitution the aire replete with thicke and foggy vapours, causes the humors to abound in the body, which forthwith easily fall upon the affected parts, and cause encrease of paine. But (saith our Adversary) in the battell at *Dreux* and at *S. Dennis* which were fought in winter, there dyed a great number of men who were wounded by Gunshot: This I confesse is true; but yet I deny, that it was occasioned by applying suppuratives, or corrosives, but rather by the vehemencie and largenesse of their wounds, and the spoile the Bullet made in their members, but above all by reason of the cold. For cold is most hurtfull to wounds and ulcers (as *Hippocrates* testifies) it hardens the skinne and causes a Gangrene. If this my Gentleman had beene with mee in the seige of *Metz*, he might have seene the Legges of many souldiers to have rotted, and presently taken with a Gangrene to have fallen away, by the onely extremitie of cold; If he will not beleieve me, let him make tryall himselfe; and goe in winter to the Chappell at Mount *Senis* one of the Alpine hills, where the bodies of such as were frozen to death in passing that way are buried, and hee shall learne and feele how true I speake. In the meane time I thinke it fit to confute the last point of his reprehension.

The similitude
betweene
Thunder and
great Ordiz-
nance, main-
tained.

He cavills for that I compared Thunder and Lightning with the discharging peices of Ordinance. First he cannot denie but that they are alike in effects. For it is certaine that the flame arising from Gunpowder set on fire, resembles Lightning; in this also that you may see it before you heare the cracke or report. I judge for that the eye almost in a moment perceives its object; but the eare cannot but in some certaine space of time, and by distinct gradations. But the rumbling noise is like in both, and certainly the report of great Ordinance may bee heard sometimes at forty miles distance, whilst they make any great battry in the beleiging of Citties.

Besides also, Iron Bullets cast forth with incredible celerity by the fiered Gunpowder, throw downe all things with a horrid force, and that more speedily and violently by how much they resist the more powerfully by their hardnesse. They report that Lightning melts the money not hurting the purse; Now many by the onely violence of the aire agitated and vehemently mooved by shooting a peice of Ordinance, as touched with Lightning, have dyed in a moment, their bones beeing shivered and broken, no signe of hurt appearing in the skinne.

The smell of Gunpowder when it is fiered, is hurtfull, firy and sulphurous, just like that which exhales or comes from bodies killed with Lightning. For men doe not onely shunne this smell, but also wilde Beasts leave their Dennes if touched with Lightnings. Now the cruelty of great Ordinance makes

no lesse spoyle amongst buildings, nor slaughter amongst men and beasts, than Lightnings doe, as wee have formerly shovne by examples, not onely horrid to see, but even to heare reported, as of Mines, the Arcenall of *Paris*, the Cittie of *Malignes*. These may seeme sufficient to reach, that Thunder and Lightning have a great similitude with the shooting of great Ordinance, which notwithstanding I would not have alike in all things. For they neither agree in substance, nor matter, but onely in the manner of violent breaking asunder the objects.

Now let us see and examine what manner of cure of wounds made by Gunshot our adversarie substitutes for ours. For hee would have suppuratives used and applied, yet such as should not be hot and moist in qualitie, or of an Emplasticke consistence, but hot and dry things. For (saith hee) here is not the same reason as in Abscesses, where the Physition intends nothing but suppuration. But heere because a confusion is present with the wound, this requires to bee ripened with suppuratives, but the wound to be dried.

Now to answer this objection, I will referre him to *Galen*, who will teach him the nature of suppuratives, from whom also hee may learne that great regard is to be had of the cause and more urgent order in the cure of compound diseases; then would I willingly learne of him, whether he can heale a wound made by Gunshot, not first bringing that which is confused to perfect maturitie. If hee affirme hee can, I will be judged by whatsoever Practitioners hee will, to judge how obscure these things are. Whereby you may the better understand there is nothing more commodious than our *Basilicon* and oyle of Whelpes to ripen wounds made by Gunshot, if so bee that putrefaction, corruption, a Gangreen or some other thing doe not hinder. Then would hee have *Oxycrate* poured into these wounds to stay their bleeding, which if it cannot so bee stayed, hee would have a medicine applied consisting of the white of an Egge, Bole Armenicke, oile of Roses and salt. But I leave it to other mens judgement, whether these medicines have power to stay bleeding if put into the wound; certainly they will make it bleede the more. For Vinegar seeing it is of a tenuious substance and biting, it is no doubt but that it will cause paine, defluxion and inflammation.

To which purpose I remember I put to stanch bleeding, for want of another remedie, a medicine wherein was some Vinegar, into a wound received by a Moore, an attendant of the Earle of *Rossy*, hurt with a Lance, run through his arme before *Bologne* by an English horseman. But he comes againe to mee a little after, complaining and crying out that all his arme burnt like fire; wherefore I was glad to dresse him againe, and put another medicine into his wound, and layd an astringent medicine upon the wound, but poured it not therein.

And then above all other remedies hee extolls his Balsame composed of Oyle of Waxe, and Myrrhe beaten together with the white of an Egge; which hee saith is equall in operation to the naturall Balsame of *Peru*. For hee affirms that this hath a facultie to consume the excrementitious humidity of wounds, and so strengthens the parts that no symptome afterwards troubles them. Yet hee saith, this doth not so well heale and agglutinate these wounds, as it doth others which are cut. Verily it is ridiculous to thinke that confused wounds can bee healed after the same manner as simple wounds may, which onely require the uniting of the loosened continuities.

Therefore neither can these Balsames be fit remedies to heale wounds made by Gunshot, seeing by reason of their drynesse they hinder suppuration, which unlesse it be procured the patient cannot be healed. Wherefore such things ought not to be put into wounds of this nature, before they be ripened, washed and clesed from their filth. Yet can I scarce conceive, where we shall be able to finde out so many Chymists which may furnish us with these things sufficiently to dresse so many wounded souldiers as usually are in an Army, or whence the souldiers shall have sufficient meanes to beare the charge thereof. Also that which he saith is absurd, that these Balsames must bee put into the wounds without Tents; and presently forgetting himselfe, hee saith, It will not bee amisse, if there bee a little and slender Tent put into the wound, which may onely serve to hinder the agglu-

bleeding.
A History.

Balsmes are fit
to heale simple
but not confu-
sed wounds.

Egyptiacum
howsoever
made is a clen-
fer not a sup-
purative.

tination thereof. But how can these Balsames come to the bottomes of wounds without Tents, when as it is their chiefe propertie to carry medicines even to the innermost parts of the wounds, and alwayes keepe open a free passage for the evacuation of the quitture? But it is note worthy, that after hee hath rejected *unguentum Egyptiacum*, hee neverthelesse bids to apply it, from the beginning untill the contusion come to perfect maturation, dissolving it in a decoction of the tops of wormewood, *S. Iohn wurt*, the lesser Centory and Plantaine, and so injecting it into the wound. Besides also a little after hee gives another way of using it, which is, to boyle a quantity of Hony of Roses in plantaine water, carefully sciming it, untill it bee boiled to the consistence of Hony, and then to adde as much *Egyptiacum* thereto, and so to make an oymntment most fit to bring these wounds to supputation. But I leave it for any skillfull in Chirurgery to judge, whether such medicines can bee suppuratives, or whether they bee not rather deterfives. Last of all hee writes, that these wounds must bee drest but every fourth day. And if there bee a fracture of the bone joynd with the wound, then to moove nothing after the first dressing untill the eighth day after; then presently in another place hee saith, it will bee good, and expedient, to drop ten or twelve droppes of the formerly described Balsame every day into the wound. Verily such doctrine which neyther agrees with its selfe nor the truth, cannot but much puzzle a Novice and young Practitioner in Chirurgery, who is not yet versed in the Art, or the operations thereof.

CHAP. XIII.

Another Apologic, against those who have laboured with new reasons to proove, that wounds made by Gunshot are poysoned.

The occasion
of this Apo-
logic.

The reasons
of our adver-
saries that the
Bullets may
be poysoned,
set downe and
confuted.

OME few monthes agoe, I visited a patient together with some learned Physitions and skillfull Chirurgions. Now they, as it oft times happens, in way of discourse, begun to argue of the condition and quality of wounds made by Gunshot, and endeavoured to proove that they might be poysoned, by five reasons. Not truly through the occasion of the Gunpowder, for they all confessed that it was free from poyson, whether you have regard to its essence, or to its composition; but by the Bullet, into which the poyson may bee transfused and incorporated. The first reason is, that Lead seeing it is of a rare and spongy nature, which the easinesse of melting and softnesse argues, is very fit to drinke and soake in what liquors so ever you please. But me thinks this conclusion is very weake; for in all mixtures made by Art, such as this is whereof wee speake, there are two things to be considered; that is to say, the matter of the things which enter into the mixture, and the forme: for the matter, such bodies must be eyther liquid, or soft or friable; and lastly such as may be broken and divided into small particles, that so they may easily in all parts concur and bee conjoynd and united. But for their forme, there ought to be a certaine affinitie, consent and sympathy. You may perceive this by water and oyle; for each of them though of a liquid substance, and such as may easily bee mixed with divers other things, yet cannot they bee mixed the one with the other by reason of their antipathy of formes. For thus gold and silver are so agreeing with Lead, that as oft as they are molten, Lead is mixed with them. But Brasse shuns Lead as much as gold and silver fly Tinne and white Lead. If therefore Brasse and Lead being melted cannot bee mixed together, though contained under the same *Genus*, and common nature of Mettalls; how then can it be commixt with another thing distinct in the whole kinde, much more in *species*, and forme, to wit, poyson? Their second reason is this; Iron, say they, which is more dense, solid, and lesse porous, may receive some venenate substance and quality, as the Arrowes of the Ancients which were dipped in poyson, testifie; therefore must Lead much

much more be capable thereof. I answer, that the surface of Iron may be poysoned, but not the inner part or substance by mixture therewith. But heere the question is of union, but not of annointing or inunction.

The third reason is thus framed; Though (say they) Lead casts off and purges it selfe from the drosse and unpure parts, yet that is no argument, that it will not commix, or soake its selfe in some strangeli liquor or body; for thus Steele, being the most solid Iron, receives the temper which hardens it by the artificiall pouring upon it or quenching it in liquors contrary thereto in their whole kind. I answer, that Steele admits into it by that quenching and tempering, none of the juices or liquors wherewith it is watred or quenched. For if that were necessary, it might be better and more easily performed, when the mettall is first cast, than when it is beaten into plates, or barres; which answer shall serve to confute their fourth reason; wherein they say, that bullets may be made so poysonous by the commixture of the juices of Muncks-hood, Oleander, Crowe-foote, and other such like things which in their whole substance are contrary to ours, that the wound which is made with them can, not but be poysoned.

But I on the contrary affirme, that mixture is onely of these things, which may not onely be put, but also sticke thereto, and be mutually united; but how can water, or any other liquid juice so much as onely sticke to Lead, as that which is a solid and firme body, it is so farre from being united therewith? You may give more certaine judgement hereof by experience, than by reason; wherefore let melted Lead be put into the foresaid juices or the like; then when the lead is cold, weigh each of them severally, and you shall finde, that both of them recaine the same weight they formerly had. Which is a most certaine argument that neither the Lead hath mixed or united it selfe with the juices, nor the juices lost any part of their substance.

Their fifth reason is thus; A Bullet shot out of a Gun against some hard stone, growes not so hot, but that you may presently without any harme take it up in your hand. Therefore it is false, that the poyson commixt and united with the Bullet can bee dissipated by the fire and flash of Gunpowder. The answer to this objection is easily. For when wee say, that although the Bullet may bee infected by poyson perfectly commixt with the Lead, yet all the force of the poyson would bee dissipated by the fire; wee would have you thus to understand us, that we doe not meane this of that fire which is made by the powder at the discharging of the Peice, but of that by force whereof the molten head is mixed and conjoynd with the venenate juice, so to make one of many. For this fire exercising its force upon the venenate juices hindred by the intercourse of no *Medium*, and that for some space of time, and not for an instant, it may, if not consume, yet much weaken their strength.

If there be any, who will not bee satisfied by these reasons, let him consult, and reade *Matthiolus*. There are (saith hee) some of these latter times wholly ignorant of things, who (if wee may say the truth) have beene so madly foolish, that they said it was fit and requisite to put Treacle and Mithidate and such like Antidotes amongst Gold and Silver that was melted to make Cuppes, that so receiving the faculties of the Antidote they might resist poyson. But how absurd and ridiculous their opinion is, let them judge (for it needs no clearer reproofe) who have but a little knowledge in naturall things, but chiefly in Mettalls.

These are my reasons, these the authorities of men excelling in learning and judgement, that confirme me in my ancient and former opinion, that wounds made by Gunshot doe not partake of any venenate qualitie.

*In prefat. l.
6. Discor.*

CHAP. XV.

How wounds made by Arrowes differ from such as are made by Gunshot.

Wounds made with Arrowes and such like things, are oftentimes without contusion. But are oftentimes poysoned.

Wounds made by Arrowes and Bolts shot out of Crosse-bowes and such like things, differ chiefly in two things, from these which are made by Gunshot. The first is, for that they are oft times without contusion, which the other never are. The other is, for that they oft times are poysoned. In both these respects, their cure is different from the other. But the cure of these wounds made by Arrowes is different in it selfe, by reason of the variety and divers sorts of Darts or Arrowes.

CHAP. XVI.

Of the diversities of Arrowes and Darts.

The differences of Arrowes.
In matter.
In figure.

In bignes.
In number.
In making.

In force.

Arowes and Darts are different amongst themselves both in matter and in forme or figure, in number, making, facultie or strength; In matter, for that some of them are of wood, some of Reeds, some are blunt headed, others have piles or heads of Iron, Brasse, Lead, Tinne, Horne, Glasse, Bone. In figure, for that some are round, others cornered, some are sharpe pointed, some barbed, with the barbs standing either to the point, or shafts, or else acrosse, or both wayes, but some are broad and cut like a Chissell. For their bignesse, some are three foote long, some lesse. For their number, they differ in that, because some have one head, others more. But they varie in making, for that some of them have the shaft put into the head, others the head into the shaft; some have their heads nailed to the shaft, others not, but have their heads so loosely set on, that by gentle plucking the shaft, they leave their heads behind them, whence dangerous wounds proceede. But they differ in force, for that some hurt by their Iron onely, others besides that, by poyson, wherewith they are infected. You may see the other various shapes here represented to you in the following Figure.

The Figures of divers sorts of Arrowes.

CHAP. XVII.

Of the difference of the wounded parts.

THe Wounded parts are cyther fleshy or bony; some are neare the joynts, others seated upon the very joynts; some are principall, others serve them; some are externall, others internall. Now in wounds where deadly signes appeare, its fit you give an absolute judgement to that effect; least you make the Art to be scandalled by the ignorant. But it is an inhumane part, and much digressing from Art, to leave the Iron in the wound; it is sometimes difficult to take it out, yet a charitable and artificiall worke. For it is much better to try a doubtfull remedy, than none at all.

You must not leave the weapon in the wound.

CHAP. XVIII.

Of drawing forth Arrowes.

You must in drawing forth Arrowes shun incisions and dilacerations of Veines and Arteries, Nerves and Tendons. For it is a shamefull and bungling part to doe more harme with your hand, than the Iron hath done. Now Arrowes are drawne forth two wayes, that is, either by extraction, or impulsion. Now you must presently at the first dressing pull forth all strange bodies, which that you may more easily and happily performe, you shall set the Patient in the same posture, as hee stood when he received his wound; and hee must also have his Instruments in a readinesse, chiefly that which hath a slit pipe and toothed without, into which there is put a sharpe iron style, like the Gimbles we formerly mentioned for the taking forth of Bullets; but that it hath no scrue at the end, but is larger and thicker, so to widen the pipe, that so widened it may fill up the hole of the Arrowes head whereinto the shaft was put, and so bring it forth with it, both out of the fleshy as also out of the bony parts, if so bee that the end of the shaft be not broken, and left in the hole of the head. That also is a fit Instrument for this purpose, which opens the other end toothed on the outside, by pressing together of the handle. You shall finde the Iron or head that lies hid by these signes, there will be a certaine roughnesse and inequalitye observable on that part if you feele it up and downe with your hand; the flesh there will be bruised, livid, or blacke, and there is heavinesse and paine felt by the patient both there and in the wound.

The manner of drawing forth Arrowes and such weapons.

A deliniation of Instruments fit to draw forth the heads of Arrowes and Darts, which are left in the wound without their shafis.

A hooked Instrument fit for to draw forth strange bodies, as peices of Maile, and such other things as it can catch hold of, which may also bee used in wounds made by Gunshot.

But if by chance either Arrows, Darts or Lances, or any winged head of any other weapon, bee run through and left sticking in any part of the body, as the Thigh, with a portion of the shaft or staffe shivered in peices, or broken off; then it is fit the Chirurgeon with his cutting mullets should cut off the end of the staffe or shaft, and then with his other mullets plucke forth the head, as you may see by this Figure.

CHAP. XIX.

How Arrows broken in a wound may be drawne forth.

When to draw forth the weapon on the contrary side.

When by the same way it went in.

But if it chance that the weapon is so broken in the wound, that it cannot bee taken hold on by the formerly mentioned Mullets, then must you draw, or plucke it out with your Crane, or Crowes bill, and other formerly described Instruments. But if the shaft be broken neare the head, so that you cannot take hold thereof with your Cranes bill, then you shall draw it forth with your Gimblet which we described before to draw forth bullets; for if such a Gimblet can be fastened in Bullets, it may farre better take hold of wood. But if the head be barbed, as usually, the English arrowes are, then if it may be conveniently done, it will be very fitting to thrust them through the parts. For if they should be drawne out the same way they went in, there would bee no small danger of breaking or tearing the Vessells and Nerves by these hooked barbes. Wherefore it is better to make a section on the other side whither the head tended, and so give it passage forth if it may bee easily done; for so the wound will bee the more easily clenfed and consolidated. But on the the contrary, if the point tend to any bone, or have many muscles or thicke flesh against the head thereof, as it happens sometimes in the Thighes, Legges and Armes; then you must not thrust the head thorough, but rather draw it out the same way it came in, dilating the wound with fit Instruments, and by skill in Anatomie shunning the larger Nerves and Vessells. Therefore for this purpose put a hollow Dilater into the wound, and therewith take hold of both the barbes or wings of the head; and then take fast hold of the head with your Cranes-bill, and so draw them forth all three together.

A Dilater hollowed on the inside, with a Cranes-bill to take hold of the barbed head.

CHAP. XX.

What to be done, when an Arrow is left fastned or sticking in a bone.

B

Ut if the weapon be so depaſt and faſtned in a bone that you cannot drive it forth on the other ſide, neither get it forth by any other way than that it entred in by; you muſt firſt gently moove it up and downe, if it ſticke very faſt in, but have a ſpeciall care that you doe not breake it, and ſo leave ſome fragment thereof in the bone; then take it forth with your Crowes bill, or ſome other fit Inſtrument formerly deſcribed. Then preſſe forth the blood, and ſuffer it to bleed ſomewhat largely, yet according to the ſtrength of the Patient and nature of the wounded part. For thus the part ſhall be eaſed of the fulneſſe and illneſſe of humors, and leſſe moleſted with inflammation, putrefaction and other ſymptomes which are cuſtomarily feared. When the weapon is drawne forth, and the wound once dreſſed, handle it, if ſimple, as you doe ſimple wounds; if compound, then according to the condition and manner of the complication of the effects; Certainly the Oyle of Whelpes formerly deſcribed is very good to allwage paine. To conclude, you ſhall cure the reſt of the Symptomes according to the method preſcribed in our Treatiſe of wounds in generall, and to that wee have formerly delivered concerning wounds made by Gunſhot.

A Caution.

The benefit of bleeding in wounds.

CHAP. XXI.

Of poyſoned wounds.

I

F theſe wounds at any time proove poyſoned, they have it from their primitive cauſe, to wit, the empoiſoned Arrowes, or Darts of their enemies. You may finde it out both by the propertie of the paine; if that it bee great and pricking, as if continually ſtung with Bees, for ſuch paine uſually enſues in wounds poyſoned with hot poyſon, as Arrowes uſually are; Alſo you ſhall know it by the condition of the wounded fleſh; for it will become pale and grow livid, with ſome ſignes of mortification. To conclude, there happen many and maligne ſymptomes upon wounds which are empoiſoned, being ſuch as happen not in the common nature of uſuall wounds. Therefore preſently after you have plucked forth the ſtrange bodies, encompaſſe the wound with many and deepe ſcarrifications, apply ventoles with much flame, that ſo the poyſon may bee more powerfully drawne forth; to which purpoſe the ſucking of the wound, performed by one whoſe mouth hath no ſoareneſſe therein, but is filled with oyle, that ſo the poyſon which he ſucks may not ſticke, nor adhere to the part, will much conduce. Laſtly, it muſt be drawne forth by rubefying, veſicatory and cauſtick medicines, and aſſailed by ointments, cataplaſmes, emplaſters, and all ſorts of locall medicines.

The ſignes of poyſoned wounds.

Remedies in poyſoned wounds.

The end of the Eleventh Booke.

[The text in this section is extremely faint and illegible. It appears to be a large block of text, possibly a letter or a page from a book, with some lines of text visible on the left and right margins.]

OF CONTUSIONS AND GANGREENS.

THE TWELFTH BOOKE.

CHAP. I.

Contusion, according to *Galen*, is a solution of Continuity in the flesh or bone, caused by the stroke of some heavy and obtuse thing, or a fall from an high. The symptome of this disease is by *Hippocrates* called *Peliosis*, and *Melasma*, that is to say, blacknesse & blewnesse; the Latins tearme it *Sugillatum*. There are divers sorts of these Sugillations or blacknesse, according as the blood is poured forth into the more inward or outward part of the body. The blood is poured

fracturis.*

Causes of
Bruises and
Sugillations.

forth into the body when any (for example) falls from an high, or hath any heavy weight falls upon him, as it often happens to such as worke in Mines, or are extremely racked or tortured; and sometimes by too loud and forcible exclamation. Besides also by a Bullet shot through the body, blood is poured forth into the bellies, and so often evacuated by the passages of the Guts and bladder. The same may happen by the more violent and obtuse blowes of a hard Trunchion, Club, Stone, and all things which may bruise and presse the blood out of the vessells either by extending or breaking them. For which causes also the exterior parts are contused, or bruised sometimes with a wound, sometimes without, so that the skinn being whole, and as farre as one can discern, untoucht, the blood poures it selfe forth into the empty spaces of the muscles, and betweene the skinn and muscles; which affect the Ancients have tearmed *Ecchymosis*; *Hippocrates* calls it by a peculiar name *Nausiosis*, for that in this affect the swollne veines seeme as it were to vomit, and verily doe vomit or cast forth the superfluous blood which is contained in them. From these differences of Contusions are drawne the indications of curing, as shall appeare by the ensuing discourse.

*Sec. 2. lib.
de fract.*

CHAP. II.

Of the generall cure of great and enormous Contusions.

He blood poured forth into the body, must bee evacuated by visible and not visible evacuation. The visible evacuation may be performed by bloodletting, Cupping-glasses, hornes, scarification, horeseleeches and fit purgative medicines; if so bee the patient have not a strong and continuall feaver; The not visible evacuation is performed by resol-

resolving and sudorifick portions, baths, & slender diet. Concerning Blood-letting Galens opinion is plaine, where he bids, in a fall from an high place, and generally for bruises upon what part soever they be, to open a veine, though the parties affected are not of a full constitution; for that unlesse you draw blood by opening a veine, there may inflammations arise from the concreate blood, from whence without doubt evill accidents may ensue. After you have drawne blood give him foure ounces of Oxycrate to drinke; for that by the tenuity of its substance hinders the coagulation of the blood in the belly, or in stead thereof you may use this following potion. *R. rad. Gentiana ʒij; bulliant in Oxycrato; in colatura dissolve rhei electi ʒj. fiat potio.* These Medicines dissolve, and cast forth by spetting and vomite the congealed blood, if any thereof be contained in the ventricle or lungs; it will be expedient to wrap the patient presently in a sheeps skinne, being hot and newly taken from the sheepe, and sprinkled over with a little myrrhe, cresses and salt, and so to put him presently in his bed, and then cover him so that he may sweat plentifully. The next day take away the sheeps-skinne, and annoint the body with the following anodyne and resolving unguent. *R. unguent. de alibaa ʒvj. olei Lumbric. chamam. anethi. an ʒij. terebinth. veneta ʒiiij. farina fenugra. rosar. rub. pulverisat. pul. myrtillorum, an ʒj. fiat litus ut dictum est.* Then give this potion which is sudorifick and dissolves the congealed blood. *R. Ligni guaiaci ʒviij. rad. enula camp. consolid. majoris, ireos Florent. polypod. querni. seminis coriandri, anisi, an ʒʒ. glycyrrhiz. ʒij. napea, centaurea, caryophyl. cardui ben. verbena, an. m. f. aque fortanæ lib. xij.* Let them bee all beaten and infused for the space of twelve houres, then let them boyle over a gentle fire untill the one halfe bee consumed; let the patient drinke some halfe pinte of this drinke in the morning, and then sweate some houre upon it in his bed, and doe this for seaven or eight dayes. If any poore man light upon such a mischance, who for want of means cannot bee at such cost, it will be good, having wrapped him in a sheete, to bury him up to the chin in Dung mixed with some hay or straw, and there to keepe him, untill he have sweat sufficiently. I have done thus to many with very good successe. You shall also give the patient potions made with syrups which have power to hinder the coagulation and putrefaction of the blood; such as syrupe of Vinegar, or Lemons, of the juice of Citrons and such others to the quantitie of an ounce dissolved in scabious, or *Carduus* water. You may also presently after the fall give this drinke, which hath power to hinder the coagulation of the blood, and strengthen the bowells. *R. Rhei electi. in pul. redacti ʒj, aqua rubia majoris, & plantagin. an. ʒj. theriaca ʒʒ. Syrupi de rosis sicci, ʒʒ, fiat potus.* Let him take it in the morning for foure or five dayes. In stead hereof you may make a potion of one dramme of *Sperma ceti* dissolved in buglosse or some other of the waters formerly mentioned, and halfe an ounce of syrupe of Maiden-haire; if the disease yeeld not at all to these formerly prescribed medicines, it will be good to give the patient for nine dayes, three or foure houres before meate some of the following powder. *R. rhei torrefacti, rad. rub. majoris, centaurei, gentiana, aristolo. rotunda, an. ʒʒ. give ʒj. heereof with syrupe of Venegar and Carduus water.* They say that the water of greene Walnuts, distilled by an Alembicke, is good to dissolve congealed and knotted blood. Also you may use bathes made of the decoction of the rootes of Orris, Elecampane, Sorrell, Fennell, Marshmallowes, Water-ferne, or Ofmund the waterman, the greater Comfery; the seeds of Fenugreece; the leaves of Sage, Marjerome; the floures of Camemile, Melilote and the like. For a warme bath hath power to rarifie the skin, to dissolve the clotted blood, by cutting the tough & mitigating the acride humors, by calling them forth into the surface of the body, and relaxing the passages thereof, so that the rebellious qualities being overcome, there ensues an easie evacuation of the matter by vomit, or expectoration, if it stode in the stomacke, or be contained in the chest; but by stooles & Urine, if it lye in the lower parts; by sweates and transpiration if it lye next under the skin. Wherefore bathes are good for those who have a *Peripneumonia* or inflammation of their Lungs, or a *Pleurisie*, according to the minde of *Hippocrates*, if so be that they be used, when the feaver begins to be allwaged; for so they mitigate paine, helpe forwards suppuration, and hasten the spitting up of the purulent matter. But we would

would not have the patient enter into the bath, unlesse he have first used generall remedies, as blood-letting and purging; for otherwise there will be no small danger, least the humors diffused by the heate of the bath, cause a new defluxion into the parts affected. Wherefore doe not thou by any meanes attempt, to use this or the like remedy, having not first had the advice of a Physicion.

CHAP. III.

How we must handle Contusions, when they are joyned with a wound.

Very great Contusion forthwith requires blood-letting, or purging, or both; and these either for evacuation, or revulsion. For thus *Hippocrates* sect. 2. lib. fract. in a contusion of the Heele, gives a vomitory potion, the same day, or else the next day after the heele is broken. And then if the Contusion have a wound associating it, the defluxion must be stayed at the beginning, with an ointment made of Bole Armenicke, the whites of egges, and oyle of roses, and myrtles, with the pouders of red roses, Allome and mastich. At the second dressing apply a digestive made of the yoałke of an egge, oyle of violets and Turpentine. This following Cataplasme shal be appyled to the neare parts to help forwards suppuration. *R. rad. albae, & lilio. an. ʒiij sol. matv. violar. senecionis, an. M. ss coquantur complete, & passentur per setaceum, addendo butyri recentis & olei viol. an. ʒiij. farine volatilis quant. sufficit; fiat cataplasma ad formam pultis liquida.* Yet have a care in using of Cataplasmes, that you do not too much exceede; for too frequent and immoderate use of them makes wounds plegmonous, fordide and putride. Wherefore the wound after it is come to suppuration must be cleansed, filled with flesh and cicatrized; unlesse haply the contused flesh shall be very much torne, so that the native heate forsake it, for then it must be cut away. But if there be any hope to agglutinate it, let it be sowed, and other things performed according to Art; but the stitches must not be made so close together, as when the wound is simple, and without contusion; for such wounds are easily inflamed and swell up, which would occasion either the breaking of the thred or flesh, or tearing of the skinne.

A suppurative Cataplasme.

A caution to be observed.

How contused wounds must be sowed

CHAP. IV.

Of these Contusions which are without a wound.

IF the skinne being whole and not hurt, as farre as can be discerned, the flesh which lyes under it be contused, and the blood poured forth under the skin make an *Ecchymosis*, then the patient must be governed according to Art untill the malignant symptomes, which commonly happen, be no more to be feared. Wherefore in the beginning draw blood on the opposite side, both for evacuation and revulsion. The contused part shall be scarified with equall scarifications; then shall you apply cupping-glasses or hornes, both for evacuation of the blood which causes the tumor and Tension in the part; as also to ventilate and refrigerate the heate of the part, least it turne into an Abscesse. Neither must we in the meane while omit gentle purging of the belly. The first topicke medicines ought to bee astringives which must lye some short while upon the part, that so the Veines, and Arteries may be as it were straitened and closed up, and so the defluxion hindered; as also that the part it selfe may be strengthened. This may be the forme of such a remedy. *R. Albumina ovorum nu. iij. olei myrtini & rosacei, an. ʒj. boli armeni, & sanguin. dracon. an. ʒb. nucum cupress. gallarum, pul. aluminis usti, an. ʒij. incorporentur omnia addendo acetiparum, fiat medicamentum.* Then you shall resolve it with a fomentation, Cataplasme, and discussing emplasters.

Phlebotomie.

Scarifying. Cupping glasses.

Astringives how good in Contusions.

After astringives must follow discutives.

CHAP. V.

By what meanes the contused part may be freed from the feare and imminent danger of a Gangrene.

Sect. 2. lib. de fract.

The cause of a Gangrene.

The use of a Scarificator.

Great Contusions are dangerous even for this cause, for that a Gangrene and mortification sometimes followes them; which *Hippocrates* teacheth to happen, when as the affected part is growne very hard and liquide. Wherefore when the part growes livide and blacke, and the native colour thereof, by reason of the afflux of the concreate blood, is almost extinct; chiefly to ease the part of that burden, cupping glasses and hornes shall be applyed to the part it selfe being first scarified with a Lancet, or else the following Instrument termed a Scarificator, which hath 18 little wheelles sharpe and cutting like a razour, which may be straitened and slacked by the pins noted by D. and P. This instrument is to be commended for that it performes the operation quickly and gently, for it makes 18 incisiones in the space that you make one with a Lancet or knife.

A Scarificator.

A. Shewes the cover. B. The Boxe, or Case.

A fomentation to discusse and draw to the skinne.

In sect. 2. lib. de fractur.

A discussing plaster.

Then shall you foment the part with strong Venegar wherein the roootes of radish or of Dragons, Cuckow-pint, *Salomons Seale*, *Auripigmentum* and the like have beene boyled; for such acride things doe powerfully heat, resolve and draw the concreate blood from the inner part of the body unto the skinne, which by its settling in the part affected, prohibits the entrance of the vitall spirits, the preservers of its integrity; yea also extinguisheth the native heate of the same part. Now wee must not use these things but with great discretion, least so we draw not onely that blood which is poured forth of the vessells, but also the other which is contained in the vessells. Moreover also we must not use them, unlesse when the defluxion is stayed. For small contusions (which *Galen* judgeth by the softnesse of the contused part) it will bee sufficient to apply to discusse them, Virgins waxe dissolved and mixed with Cummin seedes, Cloves, the roote of blacke Briony, (which hath a wonderfull faculty to discusse all blackenesses and sugillations) for the same purpose, you may also apply wormewood brused and so warmed in a dish and sprinkled over with a little white wine. Also fry wormewood with oyle of cammomill, branne, the powder of Cloves, and Nutmegs, adding thereto a little *aqua vita*, then put it all in a linnen cloth and apply it hot to the part. The following emplaster doth powerfully discusse congealed blood. R. *Picus nigra* ʒij. Gum. *Elemi*. ʒiʒ. *Syracis liquida* & *serebintb. com.* an. ʒʒ. pul. *sulphuris vivi*. ʒj. Liquefiant simul, fiat Emplastrum; and let be spred upon leather and so applyed.

CHAP. VI.

Of that strange kinde of symptome which happens upon contusions of the ribbes.

He flesh contused sometimes by great violence becomes mucous and swolne, or puffed up like Veale, which the butchers blow up, the skinne remaining whole. This is seene and happens chiefly in that flesh which is about the ribs; for this being bruised either by a blow, or fall, or rentencie, or any other such like cause; if you presse it with your hand, a certaine windisse goeth out thereof with a small whyzzing, which may be heard, and the print of your fingers will remaine as in *adema's*. Vnlesse you quickly make fit provision against this symptome, there is gathered in that space which the flesh departing from the bones, leaves empty, a certaine purulent *sanies*, which divers times foules and corrupts the ribs. It will be cured, if the mucous tumor be presently pressed, and straightly bound with ligatures, yet so that you hinder not the breathing, when as the affect happens upon the ribs and parts of the Chest. Then apply to the part a plaister of *Oxycroceum* or *diachylon Treatum* with the emplaster *de meliloto*; also discussing fomentaions shall be used.

Hip. sect. 3. lib. de art. sent. 58. & 65.

Remedies for a mucous and flatulent tumor of the ribbes. The cause.

The cause of such a tumor is a certaine mucous flegme; seeing that nature is so weake that it cannot well digest the nourishment, and assimilate it to the part: but leaves something as it were halfe concocted. No otherwise than the conjunctive coate of the eye is sometime so lifted up and swolne by a stroake, that it startes as it were out of the orbe of the eye, leaving such filth or matter as wee see those which are bleard eye to be troubled withall; because the force and naturall strength of the eyes is become more weake, either by the fault of the proper distemperature, or the abundance of moysture which flowes thither, as it happens in those tumors which are against nature. For flatulencies are easily rayfed from a watrish and flegmaticque humors wrought upon by weake heate, which mixed with the rest of the humor, the tumor becomes higher.

CHAP. VII.

A discourse of Mumia, or Mummie.

Eradventure it may seeme strange what may be the cause, why in this Treatise of curing contusions, or bruises, I have made no mention of giving Mummie either in bole, or potion to such as have falne from high places, or have beene otherwise bruised, especially seeing it is so common and usuall, yea the very first and last medicine of almost all our practitioners at this day in such a case. But seeing I understood, and had learnt from learned Physicians, that in using remedies, the indication must alwaies be taken from that which is contrary to the disease, how could I? how can any other give Mummie in this kinde of disease, seeing we cannot as yet know what Mummie is, or what is the nature and essence thereof? So that it cannot certainly be judged, whether it have a certaine property contrary to the nature and effects of contusions. This how it may have, I have thought good to relate somewhat at large; neither doe the Physicians who prescribe Mummie, nor the Authours that have written of it, nor the Apothecaries that sell it, know any certainty thereof. For if you reade the more ancient, *Serapio*, and *Avicen*, or the moderne *Matthiolus* and *Thevet*, you shall finde quite different opinions. Aske the Merchants who bring it to us, aske the Apothecaries who buy it of them, to sell it to us, and you shall heare them speake diversly hereof, that in such variety of opinions, there is nothing certaine and manifest. *Serapio* and *Avicen* have judged Mummie to bee nothing else but *Pissasphaltum*; now *Pissasphaltum* is a certaine froth or foame rising from the Sea, or Sea waters, this same foame as long as it swimmes upon the water is soft and in some sort

Mummie a frequent and usuall medicine in contusions.

The reason that the Author makes no mention thereof amongst his medicines.

The opinion of the Arabians concerning it.

Lib. 4, cap. 84.

Another opinion of Mummie.

Another.

What over Mummie usually is.

Mummie is no way good for contusions,

But hurtfully and how?

liquid: but being driven upon the shore by force of tempest, and working of the sea, and sticking in the cavities of the rockes, it concretes into somewhat a harder substance than dried pitch, as *Dioscorides* saith. *Belonius* saith, that Mummie is onely knowne to *Egypt* and *Greece*. Others write that it is mans flesh, taken from the carcases of such as are dead, and covered over in the sandes in the desertes of *Arabia*; in which Countrey they say the sands are sometimes carried and rayed up with such force and violence of the windes, that they overthrow and suffocate such passingers as they meete withall; the flesh of these dried by the sand and winde they affirme to be Mummy.

Mathiolus following the more usuall and common opinion, writes that Mummie is nothing else than a liquor flowing from the Aromaticke embalmments of dead bodies, which becomes dry and hard. For understanding whereof you must know from all manner of antiquity, that the Egyptians have beene most studious in burying and embalming their dead; not for that end that they should become medicines for such as live, for they did not so much as respect or imagine so horride a wickednesse. But either for that they held an opinion of the generall resurrection, or that in these monuments they might have something, whereby they might keepe their dead friends in perpetuall remembrance.

Thevet not much dissenting from his owne opinion, writes that the true Mummie is taken from the monuments and stony tombes of the anciently dead in Egypt, the chinkes of which tombes were closed, and cimented with such diligence; but the enclosed bodies embalmed with precious spices with such art for eternity, that the linnen vestures which were wrapt about the presently after their death may be seene whole even to this day; but the bodies themselves, are so fresh that you would judge them scarce to have been three dayes buried. And yet in those Sepulchers and Vaultes from whence these bodies are taken, there have beene some corpes of two thousand yeeres old. The same, or their broken members are brought to Venice from Syria and Egypt, and thence disperst over all Christendom. But according to the different condition of men, the matter of their embalmments were divers; for the bodies of the Nobility or Gentry are embalmed with Myrrhe, Aloes, Saffron, and other precious spices, and Drugs; but the bodies of the common sort whose poverty and want of meanes could not undergoc such cost, were embalmed with *asphaltum* or *pissasphaltum*.

Now *Mathiolus* saith that all the Mummie which is brought into these parts is of this last kinde and condition. For the Noble men and cheefe of the province so religiously addicted to the monuments of their ancestors, would never suffer the bodies of their friends, and kindred to be transported hither for filthy gaine, and such detested use, as we shall shew more at large at the end of this worke.

Which thing sometimes mooved certaine of our French Apothecaries, men wonderous audacious, and coverous, to steale by night the bodies of such as were hanged, and embalming them with salt and Drugges they dried them in an Oven, so to sell them thus adulterated in steed of true Mummie. Wherefore wee are thus compelled both foolishly and cruelly to devoure the mangled and putride particles of the carcasses of the basest people of Egypt, or of such as are hanged, as though there were no other way to helpe or recover one bruised with a fall from a high place, than to bury man by an horrid insertion in their, that is, in mans guts. Now if this Drugges were any way powerfull for that they require, they might perhaps have some pretence, for this their more than barbarous inhumanity.

But the case stands thus, that this wicked kinde of Drugges, doth nothing helpe the diseased, in that case, wherefore and wherein it is administred, as I have tryed an hundred times, and as *Thevet* witnesses, he tryed in himselfe, when as hee tooke some thereof by the advice of a certaine Iewish Physition in Egypt, from whence it is brought; but it also inferres many troublesome symptomes, as the paine of the heart or stomacke, vomiting and stinke of the mouth.

I perswaded by these reasons, doe not onely my selfe prescribe any hereof to my patients, but also in consultations, endeavour what I may, that it bee not prescribed by others. It is farre better according to *Galens* opinion

in Method. med. to drinke some oxycrate, which by its frigidty restraines the flowing blood, and by its tenuity of substance dissolves and discusses the congealed clotts thereof. Many reasons of learned Physicians (from whom I have learned this history of Mummie) drawne from Philosophy, whereby they make it apparant, that there can be no use of this or that Mummie in contusions, or against flowing or congealed blood, I willingly omit, for that I thinke it not much beneficiall to Chirurgions to insert them heere. Wherefore I judge it better to beginne to treat of Combuſtions, or Burnes.

The effects
of oxycrate in
Contusions,

CHAP. VIII.

Of Combuſtions and their differences.

ALL Combuſtions whether occasioned by Gun-powder, or by scalding oyle, water, some mettall or what things soever else, differ onely in magnitude. These first cause paine in the part, and imprint in it an unnaturall heate. Which favouring of the fire, leaves that impression, which the Greekes call *Empyreuma*. There are more or lesse signes of this impression, according to the efficacie of the thing burning, the condition of the part burned, and stay upon the same. If the Combuſtion be superficially, the skin rises into pustles and blisters, unlesse it be speedily prevented. If it be low or deepe in, it is covered with an *Eschar* or crust, the burnt flesh by the force of the fire turning into that crusty hardnesse. The burning force of the fire, upon whatsoever part it falls, leaves a hot distemper therein, condensates, contracts, and thickens the skinn, whence paine proceedes; from paine there comes an attraction of humors, from the adjacent and remote parts. These humors presently turned into warrish or serous moyſture, whilest they seeke to passe forth, and are hindred thereof by the skinn condensed by the action of the fire, they lift it up higher, and raise the blisters which we see. Hence diverse Indications are drawne, whence proceedes the variety of medicines for burnes. For some take away the *Empyreuma*, that is, the heate of the fire (as we terme it) and assuage the paine; other hinder the rising of blisters; other some are fit, to cure the ulcer, first to procure the falling away of the *Eschar*, then to cleanse, generate flesh and cicatrize it. Remedyes fit to assuage paine, and take away the fiery heate, are of two kindes; for some doe it by a cooling faculty, by which they extinguish the preternatural heate, and repress or keepe backe the blood and humors, which flow into the parts by reason of heat & paine. Others endued with contrary faculties, are hot and attractive; as which by relaxing the skin, and opening the pores, resolve and dissipate the serous humors, which yeeld both beginning, and matter to the pustles, and so by accident assuage the paine and heat. Refrigerating things, are cold water, the water of Plantaine, Night-shade, Henbane, Hemlocke; the juyces of cooling hearbes, as Purselaine, Lettuce, Plantaine, Housleeke, Poppye, Mandrake and the like. Of these some may be compounded, as some of the fore-named juyces beaten with the white of an egge; Clay beaten and dissolved in strong Venegar; roch Alome dissolved in water, with the whites of egges beaten therein; writing inke mixed with Venegar and a little Camphire; *Vnguentum nutritum*, and also *Populeon* newly made. These and the like shall be now and then renewed chiefly at the first, untill the heate and paine be gone. But these same remedyes must be applyed warme, for if they should be layd, or put to cold, they would cause paine, and consequently defluxion; besides also their strength could not passe, or enter into the part, or be brought into action; but so applyed they assuage paine, hinder inflammation and the rising of blisters.

Description
of Nutritum.

Amongst the hot and attractive things which by rarifying, drawing out, and dissolving, assuage the paine and heate of combustions, the fire challenges the first place, especially when the burning is but small. For the very common people know and finde by dayly experience, that the heate of the lightly burnt part vanishes away, and the paine is assuaged, if they hold the part which is burnt some prety while to the heate of a lighted candle, or burning coales; for the similitude causeth attraction. Thus the externall fire whilest it drawes forth the fire which is internall and inust into the part, is a remedy against the disease it caused and bred. It is also an easily made and approved remedie, if they presently after the burne apply to the grieved part raw Onions beaten with some salt. Now you must note, that this medicine takes no place, if it be once gone into an ulcer, for it would increase the paine and inflammation; but if it bee applyed when the skinne is yet whole and not excoriated, it doth no such thing, but hinders the rising of pustles and blisters. Hippocrates for this cause also uses this kind of remedy in procuring the fall of the Eschar. If any endeavour to gainday the use of this remedy by that principle in Physicke, which sayes, that contraries are cured by contraries, and therefore affirme that Onions according to the authority of Galen, being hot in the fourth degree, are not good for combustions; let him know that Onions are indeed potentially hot, and actually moyst, therefore they rarifie by their hot quality and soften the skinne by their actuall moysture, whereby it comes to passe that they attract, draw forth, and dissipate the imprinted heate, and so hinder the breaking forth of pustles; To conclude, the fire as we formerly noted, is a remedy against the fire. But neither are diseases alwayes healed by their contraryes (saith Galen) but sometimes by their like; although all healing proceede from the contrary, this word contrary, being more largely and stricktly taken; for so also a Phlegmon is often cured by resolving medicines, which healeth it by dissipating the matter thereof. Therefore Onions are very profitable for the burnt parts, which are not yet exulcerated or excoriated. But there are also many other medicines good to hinder the rising of blisters; such is new horse-dung fryed in oyle of wall nuts or Roses, and applyed to the parts. In like manner the leaves of Elder or Dane-wort boyled in oyle of nuts, and beaten with a little salt. Also quinched lime poudered and mixed with *Unguentum Rosatum*. Or else the leaves of Cuckow-pint and Sage beaten together with a little salt. Also Carpenters Glue dissolved in water and anoynted upon the part with a feather, is good for the same purpose. Also thicke Vernish which pollishers or sword cutlers use. But if the paine be more vehement, these medicines must be renewed 3 or 4 times in a day and a night, so to mitigate the bitterness of this paine. But if so be we cannot by these remedies hinder the rising of blisters, then we must presently cut them as soone as they rise, for that the humor containd in them, not having passage forth, acquires such acrimonie that it eates the flesh which lyeth under it, & so causeth hollow ulcers: So by the multitude of causes & increase of matter the inflammation groweth greater, not only for nine daies (as the common people prattle) but for farre longer time; also some whiles for lesse time, if the body be neither repleat with ill humors, nor plethoricke, and you have speedily resisted the paine and heate by fit remedies. When the combustion shall be so great as to cause an Eschar, the falling away must be procured by the use of emollient and humective medicins, as of greases, oyies, butter, with a little *basilicon*, or the following oyntment.

℞. *Mucagin. psilly. & cydon. an. ℥iiij. gummi, trag. ℥ij. extrahantur cum aqua parietaria, olei lilliorum ℥iij. cera nova q. s. fiat unguentum molle.* For ulcers and excoriationes you shall apply fit remedies, which are those that are without acrimony, such as *unguentum album camphoratum, desiccativum rubrum, unguentum rosatum*, made without Venegar, or *nutritum* composed after this manner. ℞. *lithargyri auri ℥iiij.*

ol.

ol. rosar. ℥iij. ol. de papaver. ℥iij. ung. populeon. ℥iij. camphora ʒj. fiat unguentum in mortario plumbeo secundum artem. Or oyle of Egges tempered in a Leaden mortar. Also unquenched lime many times washed and mixed with *unguentum rosatum*, or fresh butter without salt, and some yolkes of egges hard roasted. Or. *R. Butyri recent. sive sale, ustulati, & colati ʒvj. vitell. ovor. iij. cerus. lota in aqua plantag. vel rosar. ʒB. tuthia similiter lota, ℥iij. plumbi usti, & loti, ʒij. Misceantur omnia simul. fiat linimentum ut decet.* Or else, *R. cort. sambuc. viridis, & olei rosar. an. lib. j. bulliant simul lento igne, postea colentur, & adde olei ovorum ℥iij. pul. ceruss. & tuthie prepar. an. ʒj. cera alba quantum sufficit, fiat unguent. molle secundum artem.* But the quantity of drying medicines may alwayes be encreased or diminished according as the condition of the ulcer shall seeme to require. The following remedies, are fit to allwage paine, as the mucilages of Line seedes, of the seedes of *Psilium*, or Flea-wort, and quinces extracted in rosewater, or faire water, with the addition of a little camphire; and least that it dry too speedily, adde thereto some oyle of Roses. Also five or sixe yoalkes of egges mixed with the mucilages of Line seede, the seede of *Psilium*, and quinces often renewed, are very powerfull to allwage paine. The women which attend upon the people in the Hospitall in *Paris*, doe happily use this medicine against burnes. *R. Lard. confisi libram unam;* let it be dissolved in Rosewater, then strained through a linnen cloath, then wash it foure times with the water of hen-bane or some other of that kinde, then let it be incorporated with eight yolkes of new layd egge, and so make an oynment. If the smart be great, as usually it is in these kindes of wounds, the ulcer or sores shall be covered over with a peice of Tiffany, least you hurt them, by wiping them with somewhat a course cloath, and so also the matter may easily come forth, and the medicines easily enter in. Also you must have a care when the eyelids, lippes, sides of the fingers, necke, the armpits, hammes, and bending of the elbow are burnt, that you suffer not the parts to touch one the other, without the interposition of some thing; otherwise in continuance of time they would grow and sticke together. Therefore you shall provide for this, by fit placing the parts, and putting soft linnen ragges betweene them. But you must note, that deepe combustions, and such as cause a thicker *Eschar*, are lesse painefull, than such as are but onely superficially. The truth hereof you may perceive by the example of such as have their limbes cut off, and seared or cauterised with an hot Iron; for presently after the cauterising is performed they feele little paine. For this great combustion takes away the sense, the vehemencie of the sensory or thing affecting the sense, depriving the sensitive parts of their sense; As wee have formerly noted when we treated of wounds and paines of the Nerves. The falling away of such *Eschars* shall be procured by somewhat a deepe scarification which may pierce even to the quicke, that so the humors which lye under it may enjoy freer perspiration, and emollient medicines may the freelier enter in, so to soake, moysten and soften the *Eschar* that it may at length fall away. The rest of the cure shall be performed by detergent and sarcoticke medicines, adding to the former oyntments metalline powders, when the present necessitie shall seeme so to require. But wee cannot justly say in what proportion and quantity each of these may be mixed, by reason of that variety which is in the temper and consistence of bodyes, and the stubbornesse and gentlenesse of diseases. After a burne the scarre which remaineth is commonly rough, unequall, and ill favoured: therefore wee will tell you in our treatise of the plague how it must be smoothed, and made even.

I must not here omit to tell you, that Gunpowder set on fire doth often so penetrate into the flesh, not ulcerating nor taking off the skinne, and so insinuate and throughly fasten it selfe into the flesh by its tenuity, that it cannot be taken or drawne out thence by any remedies, no not by *Phenigmes* nor vesicaryes, nor scarification, nor ventoses, nor hornes, so that the prints thereof alwayes remaine, no otherwise than the markes which the Barbarians burne in their slaves which cannot afterwards be taken away or destroyed by any Art.

CHAP. X.

Of a Gangrene and Mortification.

ERTAINELY the maligne symptomes which happen upon wounds, and the solutions of Continuity are many, caused either by the ignorance or negligence of the Chirurgion; or by the Patient, or such as are about him; or by the malignity and violence of the disease; but there can happen no greater than a Gangrene, as that which may cause the mortification and death of the part, and oft times of the whole body; wherefore I have thought good in this place to treat of a Gangrene, first giving you the definition, then shewing you the causes, signes, prognosticks, & lastly the manner of cure. Now a Gangrene is a certaine disposition, and way to the mortification of the part, which it seafeth upon, dying by little and little. For when there is a perfect mortification, it is called by the Greekes *Sphacelos*, by the Latines *Syderatio*, our countrymen terme it the fire of Saint *Anthony* or Saint *Marcellus*.

Gal. 21 ad
Glaucnem.

CHAP. XI.

Of the generall and particular causes of a Gangrene.

The generall
cause of a
Gangrene.

The prticular
causes.

Cold causeth
a Gangrene.

HE most generall cause of a Gangrene is, when by the dissolution of the harmony and joynt temper of the foure first qualities, the part is made unapt to receive the faculties, the Naturall, Vitall, and Animall spirits, by which it is nourished, lives, feelles, and mooves. For a part deprived by any chance of these, as of the light, languishes and presently dyes. Now the particular causes are many: and these either primitive; or antecedent. The primitive or externall are combustions, caused by things either actually or potentially burning; actually as by fire, scalding oyle or water, gunpowder fired and the like. But potentially by acride medicines; as Sublimate, vitrioll, potentiall cauteries and other things of the same nature: for all these cause a great inflammation in the part. But the ambient ayre may cause great refrigerations, and also a Gangrene, which caused *Hippocrates lib. de Aer.* to call great refrigerations of the braine *Sphacelisme*. Therefore the unadvised and unfit application of cold and narcoticke things, a fracture, luxation and great contusion, too strait bandages, the biting of beasts, especially of such as are venomous; a puncture of the Nerves and Tendons, the wounds of the nervous parts and joynts, especially in bodyes which are plethorike and replete with ill humors, great wounds whereby the vessels which carry life are much cut, whence an *aneurisma*, and lastly many other causes, which perturb that harmony of the foure prime qualities which we formerly mentioned, and so inferre a Gangrene.

CHAP. XII.

Of the Antecedent causes of a Gangrene.

How defluxions
cause a
Gangrene.

An uncureable
Gangrene.

OW the antecedent or internall and corporeall causes of a Gangrene, are plentifull and abundant defluxions of humors hot or cold, falling into any part. For seeing the faculty of the part is unapt and unable to sustaine and governe such plenty of humors, it comes to passe that the native heate of the part is suffocated and extinct for want of transpiration. For the Arteries are hereby so shut or pent up in a strait, that they cannot performe their motions of contraction and dilatation, by which their native heate is preserved and tempered. But then the Gangrene is chiefly uncureable when the influx of humors

mours first takes hold of the bones, and inflammation hath its beginning from them. For in the opinion of *Galen*; all these kind of affects which may befall the flesh, are all so incident to the bones. Neyther onely a Phlegmon or inflammation, but also a rottenesse and corruption doth oft times first invade and beginne at the bones; for thus you may see many who are troubled with the Leprosie and French disease; to have their skinn and flesh whole and faire to looke, on whose bones notwithstanding are corrupt and rotten, and oft times are much decayed in their proper substance. This mischief is caused by a venemous matter, whose occult quality wee can scarce expresse by any other name than poyson inwardly generated. Oft times also there is a certaine acrid and stinking filth generated in flesh with a malignant and old ulcer, with which if the bones chance to bee moistned they become foule and at length mortified: of which this saying of *Hippocrates* is extant, Vlcers of a yeares continuance or longer, must necessarily foule the bone, and make the scarres hollow.

Lib. de humor. fraternatior.

Aph. 5, sect. 6.

Whither also belongs this saying of the same party; An *Erysipelas* is ill in the laying bare of a bone. But this flowing venenate and gangrenous matter is somewhiles hot as in pestilent Carbuncles, which in the space of foure and twenty houres by causing an *escharre*, bring the part to mortification: otherwhiles cold, as wee see it divers times happens in parts which are posselt with a Gangrene, no paine, tumor, blacknesse, nor any other precedent signe of a Gangrene going before. For *Iohn de Vigo* saith, that happened to a certaine gentlewoman of *Genoa* under his cure.

A Gangrene by efflux of a cold matter.

I remember the same happened to a certaine man in *Paris*, who supping merrily and without any sense of paine, went to bed, and suddainly on the night time a Gangrene seized on both his legges, caused a mortification without tumor, without inflammation; onely his legges were in some places spred over with livid, blacke and greene spots, the rest of the substance retaining his native colour: yet the sense of these parts was quite dead, they felt cold to the touch, and if you thrust your lancet into the skinn no blood came forth.

A notable History.

A Councell of Physicians being called, they thought good to cut the skinn, and flesh lying under it, with many deepe scarifications; which when I had done, there came forth a little blacke, thicke and as it were congealed blood; wherefore this remedy as also diverse other, proved to no purpose, for in conclusion a blackish colour comming into his face, and the rest of his body, he dyed franticke. I leave it to the Readers judgement, whether so speedy, and suddainly cruell a mischief could proceede from any other than a venenate matter; yet the hurt of this venenate matter is not peculiar, or by its selfe.

For oft times the force of cold, whether of the encompassing ayre, or the too immoderate use of Narcoticke medicines, is so great, that in a few houres it takes away life from some of the members, and diverse times from the whole body, as we may learne by their example, who travell in great snowes, and over mountaines congealed, and horrd with frost & yce. Hence also is the extinction of the native heate and the spirits residing in the part, and the shutting forth of that which is sent by nature to ayde or defend it. For when as the part is bound with rigide cold, and as it were frozen, they cannot get nor enter therein. Neither if they should enter into the part, can they stay long there, because they can there finde no fit habitation, the whole frame and government of nature being spoyled, and the harmony of the foure prime qualities destroyed, by the offensive dominion of predominant cold their enemy, whereby it cometh to passe, that flying back from whence they first came, they leave the part destitute and deprived of the benefit of nourishment, life, sense and motion.

Simple cold may cause a Gangrene.

A certaine Briton an Hostler in *Paris*, having drunke soundly after supper, cast himselfe upon a bed; the cold ayre comming in at a window left open, so tooke hold upon one of his legges, that when he waked forth of his sleepe, he could neither stand nor goe. Wherefore thinking onely that his leg was numbe, they made him stand to the fire; but putting it very nigh, he burnt the sole of his foote without any sense of paine, some fingers thickenesse, for a mortification had already possessed more than halfe his legge. Wherefore after he was carried to the Hospitall, the Chirurgion who

A History.

who belonged thereto, endeavoured by cutting away of the mortified legge to deliver the rest of the body from imminent death; but it proved in vaine; for the mortification taking hold upon the upper parts, he dyed within three dayes, with troublesome belching and hicketting, raving, cold sweate, and often swoounding. Verily all that same winter, the cold was so vehement that many in the Hospitall of *Paris* lost the wings or sides of their nose-thrills, seized upon by a mortification without any putrefaction.

What parts
are usually tar-
ken by a Gang-
greene occasi-
oned by cold.

But you must note, that the Gangrene which is caused by cold, doth first and principally seaze upon the parts most distant from the heart, the fountaine of heate, to wit, the feete and legges; as also such as are cold by nature, as gristly parts, such as the nose and eares.

cold.

Signes of
Gangrenes
proceeding
from strait
bandages, or
ligatures, &c.

Signes of a
Gangrene
occasioned by
a bite, pun-
cture, &c.

He signes of a Gangrene which inflammation or a phlegmon hath caused, are paine and pulsation without manifest cause, the sudden changing of the fiery and red colour into a livid or blacke, as *Hippocrates* shewes where hee speakes of the Gangrene of a broken heele. I would have you here to understand the pulsiflicke paine not onely to be that which is caused by the quicker motion of the Arteries, but that heavy and pricking which the contention of the unaturall heate doth produce by raising a thicke cloud of vapours from these humours which the Gangrene sets upon. The signes of a Gangrene caused by cold, are, if suddenly a sharpe pricking and burning paine assaileth the part; for *penetrabile frigus adurit* (i) peircing cold doth burne: if a shining rednesse as if you had handled snow, presently turne into a livid colour; if instead of the accidentall heate which was in the part, presently cold and numbnesse shall possesse it, as if it were shooke with a quartain feaver. Such cold if it shall proceede so farre as to extinguish the native heate, bringeth a mortification upon the Gangrene; also oft times convullions and violent shaking of the whole body, wondrous troublesome to the braine and the fountains of life. But you shall know Gangrenes caused by too streight bandages, by fracture, luxation, and contusion, by the hardnesse which the attraction and flowing downe of the humors hath caused; little pimples or blisters spreading or rising upon the skinne by reason of the great heate, as in a combustion; by the weight of the part occasioned through the defect of the spirits not now sustaining the burden of the member; and lastly from this, the pressing of your finger upon the part, it will leave the print thereof as in an *edema*; and also from this, that the skinne commeth from the flesh without any manifest cause.

Now you shall know Gangrenes arising from a bite, puncture, *aneurisma*, or wound in plethoricke and ill bodies, and in a part indued with most exquisite sence, almost by the same signes as that which was caused by inflammation.

For by these and the like causes, there is a farre greater defluxion and attraction of the humors than is fit, when the perspiration being intercepted and the passages stopt, the native heate is oppressed and suffocated. But this I would admonish the young Chirurgeon, that when by the forementioned signes hee shall finde the Gangrene present, that hee doe not deferre the amputation for that hee findes some sence, or small motion yet residing in the part.

For oft times the affected parts are in this case mooved not by the motion

motion of the whole muscle, but onely by meanes, that the head of the muscle is not yet taken with the Gangrene: with mooving it selfe by its owne strength, also mooves its proper and continued tendon and taile though dead already; wherefore it is ill to make any delay in such causes.

CHAP. XIII.

Of the Prognostickes in Gangreens.

Having given you the signes and causes to know a Gangrene; it is fit wee also give you the prognosticke. The fearcenesse and malignity thereof is so great, that unlesse it be most speedily withstood the part it selfe will dye, and also take hold of the neighbouring parts by the contagion of its mortification: which hath beene the cause that a Gangrene by many hath beene termed an *Esthiomenos*. For such corruption creepes out like poyson, and like fire eates gnawes and destroyes all the neighbouring parts, untill it hath spread over the whole body. For as *Hippocrates* writes, *Lib. de vulner. capitis; Mortui & viventis nulla est proportio (i)* There is no proportion betwene the dead and living. Wherefore it is fit presently to separate the dead from the living; for unlesse that be done, the living will dye, by the contagion of the dead. In such as are at the point of death a cold sweat flowes over all their bodyes: they are troubled with ravings, and watchings, belchings, and hicketing molest them; and often swooundings invade them, by reason of the vapours abundantly and continually raysed from the corruption of the humors and flesh, and so carryed to the bowells and principall parts, by the Veines, Nerves, and Arteries. Wherefore when you have foretold these things to the friends of the patient; then make haste to fall to your worke.

Why a Gangrene is called *Esthiomenos*.

The quickest impatient of the dead.

CHAP. XV.

Of the generall cure of a Gangrene.

The Indications of curing Gangrenes are to be drawne from their differences, for the cure must bee diversely instituted according to the essence and magnitude. For some Gangrenes possesse the whole member; others onely some portion thereof; some are deepe; other some superficially onely. Also you must have regard to the temper of the body. For soft and delicate bodyes, as of children, women, Eunuches, and idle persons, require much milder medicines, than those who by nature and custome, or vocation of life, are more strong and hardy, such as husbandmen, labourers, mariners, huntsmen, porters, and men of the like nature who live sparingly and hardly. Neither must you have respect to the body in generall, but also to the parts affected; for the fleshy and musculous parts, are different from the solide, as the Nerves and joynts, or more solide, as the *Vertebra*. Now the hot and moist parts, as the Privities, mouth, wombe, and fundament, are easilier and sooner taken hold of by putrifaction; wherefore we must use more speedy meanes to helpe them. Wherefore if the Gangrene be cheefely occasioned from an internall cause, he must have a dyet prescribed for the decent and fitting use of the sixe things not naturall. If the body be plethoricke, or full of ill humors; you must purge, or let blood by the advice of a Physitian. Against the ascending up of vapours to the noble parts, the heart must cheefely be strengthened with Treacle dissolved in Sorrell, or *Carduus* water; with a bole of Mithridate, the conserves of Roses & Buglosse; and with Opiates made for the present purpose according to Art; this following Apozeme shall be outwardly applyed to the region of the heart. *Re. aque rosar. & nenuphar. an. ℥iiij. aceti scillitici ℥j. corallorum santalorum alborum & rubrorum, rosar. rub. in pulver. radaetorum, & spody, an. ℥j. mithrid. & theriaca, an. ℥iiss.*

Various Indications of curing of a Gangrene.

What parts soonest taken hold of by a Gangrene.

A cordiall Euphema.

℞i℞. trochiscorum de Caphura, ℞ij. flor. cordial. in pollin. redactarum, p.ij. croci ℞j. ex omnibus in pollinem redactis, fiat epibema. Which may be applyed upon the region of the heart with a scarlet clot or sponge. These are usually such as happen in the cure of every Gangrene.

CHAP. XVI.

Of the particular cure of a Gangrene:

The cure of a Gangrene made by inflammation.

The cure of a Gangrene, caused by the too plentiful and violent defluxion of humors suffocating the native heate, by reason of great Plegmons, is performed by evacuating and drying up the humors, which putrifie by delay and collection in the part. For this purpose scarifications and incisions, great, indifferent, small, deepe and superficially according to the condition of the Gangrene, are much commended; that so the burdened part may enjoy the benefit of perspiration; and the contained humors, of diffation, or evacuation of their stoothy excrements. Let incisions be made when the affect is great, deepe in, and neere to mortification. But scarifications may be used when the part first begins to putrefie; for the greatnesse of the remedy must answer in proportion to that of the disease. Wherefore if it penetrate to the bones, it will bee fit, to cut the skin and flesh with many and deepe incisions, with an incision knife made for that purpose; yet take heede of cutting the larger nerves and vessels, unlesse they be wholly putrified, for if they be not yet putrified, you shall make your incisions in the spaces betweene them; if the Gangrene be lesse, we must rest satisfied with onely scarifying it. When the scarifications and incisions are made, we must suffer much blood to flow forth, that so the conjunct matter may bee evacuated. Then must we apply and put upon it such medicines as may by heating, drying, resolving, cleansing and opening, amend and correct the putrefaction, and by peircing to the bottome may have power to overcome the virulencie already impact in the part. For this purpose Lotions made of the lye of the Ashes of fig-tree, or Oake wherein Lupines have bin thoroughly boyled are good. Or you may with lesse trouble make a medicine with salt water, wherein you may dissolve Aloes and *Egyptiacum*, adding in the conclusion a little *Aqua vite*; for *aqua vite* and calcined vitrioll are singular medicines for a Gangrene. Or, *R. acet. opimi ℞j. mel. ros. ℞iiij. syrup. acetosi ℞ij. salis com. ℞v. bulliant simul, adde aq. vite. ℞j.* Let the part be frequently washed with this medicine, for it hath much force to repress Gangrenes. After your Lotion, lay *Egyptiacum* for a Liniment and put it into the incisions; for there is no medicine, more powerfull against putrefaction, for by causing an *Eschar*, it separates the putride flesh from the sound. But we must not in this kinde of affect expect that the putride flesh may of it selfe fall from the sound; but rather cut off with your incision knife or sissors, whatsoever thereof you can, & then put to it *Egyptiacum* as oft as neede shall require. The knowledge hereof may be acquired from the colour, smell, and sensiblenesse of the flesh its selfe. The description of the *Egyptiacum*, whose wondrous effects I have often tryed in these causes, is this. *R. flor. aris, aluminis rock. mellis com. an. ℞iiij. acet. acer-rimi ℞v. salis com. ℞j. vitrioli rom. ℞℞. sublimati pul. ℞ij. bulliant omnia simul ad ignem, fiat unguent.* If the force of the putrefaction in the part be not so great, a weaker *Egyptiacum* may serve. When you have put in the *Egyptiacum*, then presently lay the following Cataplasme thereupon. For it hinders putrefaction, resolves, cleanses & dries up the virulent *sanies*, and by the dry subtilty of the parts penetrates into the meamber, strengthens it, and asswages the paine. *R. farin. fabar. bordei. orobi. lent. lupin. an. ℞℞. sal. com. mellis rosat. an. ℞iiij. succi absinth. marrub. an. ℞i℞. aloes, mastiches, myrrha, & aqua vit. an. ℞ij. oxymelitis simpl. quantum sufficit, fiat Cataplasma molle secundum artem;* Somewhat higher than the part affected, apply this following astringent, or defensive, to hinder the flowing down of the humors into the part, and the rising up of the vapours from the putride part into the whole body. *R. olei rosati, & myrtill. an. ℞℞. succi plantag. solani, sempervivi, an. ℞ij. album ovorum s. boli armeni, terra sigillata subtiliter pulverisatorum, an. ℞j. oxycrati quantum sufficit, misce ad usum dictum.*

The description of an *Egyptiacum*.

Astringents that may be used in cure of a Gangrene.

But

But these medicines must be often renewed. If the greese be so stubborne, that it will not yeeld to the described remedies, wee must come to stronger, to wit, Cauteries, after whose application, *Galen* bids to put upon it the juice of a Leeke with salt beaten and dissolved therewith, for that this medicine hath a peircing and drying faculty, and consequently to hinder putrification. But if you prevaile nothing with Cauteries, then must you come to the last remedy and refuge, that is, the amputation of the part; For according to *Hippocrates*, to extreame diseases exquisitely extreame remedies are best to be applyed. Yet first be certaine of the mortification of the part; for it is no little or small matter to cut off a member without a cause.

Gal. 2. ad
Clauonem.Aphor. 6. sect.
11.

Therefore I have thought it fit to set downe the signes, whereby you may know a perfect and absolute mortification.

CHAP. XVII.

The signes of a perfect Necrosis or Mortification.

You shall certainly know that a Gangrene is turned into a Sphacell, or mortification, and that the part is wholly and thoroughly dead, if it looke of a blacke colour, and bee colder than stone to your touch, the cause of which coldnesse is not occasioned by the frigiditie of the aire; if there bee a great softnesse of the part, so that if you presse it with your finger it rises not againe, but retaines the print of the impression. If the skinne come from the flesh lying under it, if so great and strong a smell exhale (especially in an ulcerated Sphacell) that the standers by cannot endure or suffer it; if a sanious moisture, viscid, Greene or blackish flow from thence; if it bee quite destitute of sense and motion, whether it be pulled, beaten, crushed, pricked, burnt, or cut off. Here I must admonish the young Chirurgion, that hee be not deceived concerning the losse or privation of the sense of the part.

For I know very many deceived as thus; the patients pricked on that part would say they felt much paine there. But that feeling is oft deceiptfull, as that which proceeds rather from the strong apprehension of great paine which formerly reigned in the part, than from any facultie of feeling as yet remaining. A most cleare and manifest argument of this false and deceitful sense appeares after the amputation of the member; for a long while after they will complaine of the part which is cut away.

A note concerning the
unsensibleness
of the part.

Verily it is a thing wondrous strange and prodigious, and which will scarce be credited, unlesse by such as have seene with their eyes, and heard with their eares the patients who have many moneths after the cutting away of the Legge, grievously complained that they yet felt exceeding great paine of that Leg so cut off. Wherefore have a speciall care least this hinder your intended amputation, a thing pittifull, yet absolutely necessary for to preserve the life of the patient and all the rest of his body, by cutting away of that member which hath all the signes of a Sphacell and perfect mortification; for otherwise the neglected fire will in a moment spread over all the body, and take away all hope of remedy; for thus *Hippocrates* wisheth: That Sections, Visions, and Terebrations must bee performed as soone as neede requires.

A wondrous
symptome.Sect. 7. Lib. 6.
Epidem.

CHAP. XVIII.

Where Amputation must be made.

It is not sufficient to know that Amputation is necessary; but also you must learne in what place of the dead part, it must bee done, and herein the wisdome and judgement of the Chirurgion is most apparent. Art bids

The contras
very decided.

to take hold of the quicke, and to cut off the member in the sound flesh; but the same art wisheth us, to preserve whole that which is sound, as much as in us lies. I will shew thee by a familiar example how thou maist carry thy selfe in these difficulties. Let us suppose, that the foote is mortified even to the ankle; here you must attentively marke in what place you must cut it off. For unlesse you take hold of the quicke flesh in the amputation, or if you leave any putrefaction, you profit nothing by amputation, for it will creepe and spread over the rest of the body. It befits Physicke ordained for the preservation of mankind, to defend from the iron or instrument and all manner of injurie, that which enjoyes life and health. Wherefore you shall cut off as little of that which is sound as you possibly can; yet so that you rather cut away that which is quicke, than leave behind any thing that is perished, according to the advice of *Celsus*. Yet oft times the commodity of the action of the rest of the part, and as it were a certaine ornament thereof, changes this counsell. For if you take these two things into your consideration they will induce you in this propounded case and example, to cut off the Legge some five fingers breadth under the knee. For so the patient may more fitly use the rest of his Legge and with lesse trouble, that is, he may the better goe on a wooden Legge; for otherwise, if according to the common rules of Art, you cut it off close to that which is perished, the patient will be forced with trouble to use three Legges instead of two.

An observable History.

For I so knew Captaine *Francis Clerke*, when as his foote was stricken off with an iron bullet shot forth of a man of warre, and afterwards recovered and healed up, hee was much troubled and wearied with the heavy and unprofitable burden of the rest of his Legge, wherefore though whole and sound he caused the rest thereof to be cut off, some five fingers breadth below his knee, and verily hee useth it with much more ease and facility than before in performance of any motion. Wee must doe otherwise if any such thing happen in the Arme; that is, you must cut off as little of the sound part as you can. For the actions of the Legges much differ from these of the armes, and chiefly in this that the body rests not, neither is carried upon the armes, as it is upon the feete and Legges.

CHAP. XIX.

How the section or amputation must be performed.

The Ligature of the part.

THe first care must be of the patients strength, wherefore let him be nourished with meats of good nutriment, easie digestion, and such as generate many spirits; as with the yolkes of Egges, and bread tosted and dipped in Sacke or Muskedine. Then let him be placed, as is fit, and drawing the muscles upwards toward the sound parts, let them be tyed with a strait ligature a little above that place of the member which is to be cut off, with a strong and broad fillet like that which women usually bind up their haire withall; This ligature hath a threefold use; the first is, that it hold the muscles drawne up together with the skin, so that retiring backe presently after the performance of the worke, they may cover the ends of the cut bones, and serve them in stead of boulders or pillowes when they are healed up, and so suffer with lesse paine the compression in sustaining the rest of the body; besides also by this meanes the wounds are the sooner healed and cicatrized; for by how much more flesh or skinne is left upon the ends of the bones, by so much they are the sooner healed and cicatrized. The second is, for that it prohibites the fluxe of blood by pressing and shutting up the veines and arteries. The third is, for that it much dulls the sense of the part by stupefying it; the animall spirits by the strait compression being hindred from passing in by the Nerves. Wherefore when you have made your ligature, cut the flesh even to the bone with a sharpe and well cutting incision knife, or with a crooked knife, such as is here expressed.

A crooked knife fit for dismembring; or a dismembring knife.

Now you must note, that there usually lyes betweene the bones, a portion of certaine muscles, which you cannot easily cut with a large incision or dismembring knife; wherefore you must carefully divide it and separate it wholly from the bone, with an instrument made neatly like a crooked incision knife. I thought good to advertise thee hereof; for if thou shouldest leave any thing besides the bone to bee divided by the saw, you would put the patient to excessive paine in the performance thereof; for soft things as flesh tendons and membranes, cannot be easily cut with a saw. Therefore when you shall come to the bared bone, all the other parts being wholly cut asunder and divided, you shall nimbly divide it with a little saw about some foote and three inches long, and that as neare to the sound flesh as you can. And then you must smooth the front of the bone which the saw hath made rough.

A caution to be observed.

The Figure of such a Saw.

CHAP. XX.

How to stanch the bleeding when the member is taken off.

Hen you have cut off and taken away the member, let it bleed a little according to the strength of the patient, that so the rest of the part may afterwards be lesse obnoxious to inflammation and other symptomes; Then let the Veines and Arteries be bound up as speedily and streightly as you can; that so the course of the flowing blood may bee stopped and wholly stayed. Which may be done by taking hold of the vessells with your Crowes beake, whereof this is the figure.

The Crowes beake fit for to draw the vessells forth of the flesh wherein they lye hid, that so they may be tyed or bound fast.

The ends of the vessells lying hid in the flesh, must be taken hold of & drawn with this instrument forth of the muscles whereinto they presently after the amputation withdrew themselves, as all parts are still used to withdraw themselves towards their originalls. In performance of this worke, you neede take no great care, if you together

How to draw forth the vessells and binde them.

with the vessells comprehend some portion of the neighbouring parts, as of the flesh, for hereof will ensue no harme; but the vessells will so bee consolidated with the more ease, than if they being bloodlesse parts should grow together by themselves. To conclude, when you have so drawne them forth, binde them with a strong double thred.

CHAP. XXI.

How after the blood is stanchd, you must dresse the wounded member.

How the lips
of the dismem-
bered part are
to be joynd
together.

When you have tyed the Vessells, loose you Ligature which you made above the place of amputation; then draw together the lippes of the wound with foure stiches made acrosse, having taken good hold of the flesh; for thus you shall draw over the bones that part of the skinne and cut muscles drawne upwards before the amputation, and cover them as close as you can, that so the ayre may the lesse come at them, and that so the wound may bee the more speedily agglutinated. But when wee say, draw together the lippes of the wound with foure stiches, you must not so understand it, as that you must endeavour, to draw them so close as to touch each other, for that is impossible, for the stiches would sooner breake out, and so the part would lye bare. Wherefore it will be sufficient to draw them indifferent close together, that so you may suffer the skinne and flesh thereunder to enjoy its former liberty which it posselt before the drawing up, and so in fine by natures assistance, the wound may be the more easily agglutinated.

CHAP. XXII.

How you must stoppe the bleeding, if any of the bound up vessells chance to get loose.

Hebusinke hitherto being performed as we said, if peradventure it happen that any bandage of any of the vessells be unloosed, then must you againe binde the member with that kinde of Ligature which you did before the amputation thereof. Or else, which is better, more easily and lesse painefull, let your servant taking hold of the member with both his hands, pressing his fingers strait, stoppe the passage of the loosed vessell, for so hee may stanch the bleeding. Then let the worke-master take a needle some foure fingers long, square, and having sharpe edges, drawing after it a three or foure doubled strong thred. With this let him binde the vessell after the following manner. Let him thrust his needle on the outside into the flesh, some halfe fingers breadth from the loosed vessell untill he come to the end thereof, then let him put it about it, and bring it backe againe, but so that there be no more than the space of a fingers bredth betweene the going in, and comming forth of the needle. In this space let him put a linnen ragge three or foure times doubled, and thereupon bind somewhat strait the two ends of the thred together. For so he shall hinder the knot from hurting the flesh which lyes under it in the bindings, and also adde strength thereto. For so the bound up orifice of the vessell will in short space be agglutinated to the adjoyning flesh, and that so firmly, that there hath never beene scene, any one drop of blood to have flowed from a vessell so bound up. But if the blood which flowes forth proceede from any small vessell, you must not use this suture and ligature, nor make any such great matter thereof; for it will quickly be stanchd by the only application of Astringents presently to be mentioned,

The Hemorrhagie of small
vessels is not
to be regarded

CHAP. XXIII.

How to performe the residue of the cure of the amputated member.

Now must we shew what medicines are fitting to be applyed after the amputation of a member; which are Emplasticks, as these which exceedingly conduce to greene wounds. As *℞. boli arm. ℥iiij. farin. vol. ℥ij. picis, resina, an. ℥ij. pulverisentur omnia subtiliss. & simul mixtis fiat pulvis;* herewith let the wound bee strewed, and lay thereupon dry Lint; but let the following repercussive or defensitive be applyed to the member.

An emplastick
medicine.

℞. Album ovorum vj. boli arm. sang. drac. gypsi, terra sigill. aloes, mastiches, gallar. com. bust. an. ℥ij. in pollinem redigantur omnia, & bene agitentur, addendo olei rosarum & myr. sil. an. ℥j. fiat defensivum ad formam mellis. This ointment must bee applyed upon stoopes dipped in Oxycrate, and that so that it may not onely cover the cut member, but also be spread further and cover the neighbouring parts; as when the Legge is cut off, it must bee laid upon the joynt, and spread higher than the knee, some foure fingers upon the thigh; for it hath not onely a repercussive facultie, but it also strengthens the part, hinders defluxion by tempering the blood, aswaging paine, and hindring inflammation. It will also be good to moisten your double clothes and bandages in Oxycrate; then must you place the member in an indifferent posture upon a pillow stuffed with oaten huskes or chaffe, Stagges haire, or wheate branne. It must not be stirred after the first dressing (unlesse great necessity urge) for foure dayes in winter, but somewhat sooner in summer. For the ligatures wherewith the vessells are bound, they must not be loosed, or otherwise taken away, before the mouthes of the vessells are covered with their glue or flesh, lest by too much haste you cause a new flux of blood. This agglutination will be performed by applying refrigerating, astringent, and emplasticke medicines, such as this following powder.

A repercussive.

How to place
the member
and how often
to dress it.

℞. boli arm. farin. hord. picis, res. gypsi, an. ℥iiij. Aloes, nucum cup. cort. granat. an. ℥j. incorporantur omnia simul, fiat pulvis subtilis: herewith let the whole ulcer be strewed over for three or foure dayes space; which being ended, let onely the seates of the vessells be poudered therewith, and that for eight or ten dayes, so that wee neede no further doubt of the agglutination of the vessells. In the meane space let the digestive be applyed to the rest of the Vicer untill it bee come to suppuration; for then you shall give over your digestive, and betake you to deterstive and mundificative medicines: As

An emplastick
powder.

℞. terebinth. ven. lota in aqua vita ℥vj. mellis ros. colati ℥iiij. succi plantag. Apj. centaur. minoris, an. ℥ij. bulliant omnia simul usque ad consumptionem succorum: auferantur ab igne, addendo farina fab. & hord. an. ℥j. theriac. Gal. ℥℔. aloes, myrrha, aristoloch. an. ℥iiij. croci ℥j. fiat mundificativum.

Deterstives.

But seeing the case stands so that the Patients imagine they have their members yet entire, and yet doe complaine thereof (which I imagine to come to passe, for that the cut nerves retire themselves towards their originall, and thereby cause a paine like to convulsions; for as *Galen* writes in his booke, *De motu musculorum*, That contraction is the true and proper action of a nerve and muscle: and againe, extension is not so much an action as a motion:) now wee must indeavour to give remedy to this symptome. Which may be done by annointing the spine of the backe and all the affected part with the following Liniment, which is very powerfull against Convulsions, the Palsie, numnesse, and all cold affects of the nervous bodies.

Why after

How to procure the falling away of the ends of the bones.

Cathæreticks.

binth. ℥iij. axung. hum. ℥ij. croci ℥j. vini albi odoriferi lib. j. cera quantum sufficit, contundenda contundantur, pulverisanda pulverisentur, deinde macerentur omnia in vino per noctem, postea coquantur cum oleo & axungia prædictis in vase duplici, fiat linimentum secundum artem, in fine adde aqua vitæ ℥iij. Besides, in dressing these wounds, the Chirurgion must use diligence to procure the falling away of the ends or scalls of the bones, which the saw and the appulse of the aire never before comming hereto, have tainted; which may be done by applying to their ends actual cauteries, that is, hot irons, in using of which you must have a speciall care that you touch not the sensible parts with fire; neither must the bones themselves bee forcibly pluckt off, but gently mooved by little and little, so that you shall thinke you and the patient have exceedingly well performed your parts if they fall away at the thirtieth day after the Amputation. All these things being performed, you shall hinder the growth of proud flesh with the cathæreticks, such as are burnt vitrioll, the powder of Mercurie, and other things, amongst which is Alome burnt and powdered, which is excellent in these kind of wounds whether by its selfe or mixed with others. You shall use these and such like, even unto the perfect agglutination and cicatrization of the wound, and you may of your selfe devise other things, such as these, as occasion shall offer its selfe.

CHAP. XXIII.

What just occasion moved the Author to devise this new forme of remedy, to stanch the blood after the amputation of a member, and to forsake the common way used almost by all Chirurgions, which is, by application of actual cauteries.

Hot Irons not to be used.

Verily I confesse, I formerly have used to stanch the bleeding of members after amputation, after another manner than that I have a little before mentioned. Whereof I am ashamed, and agreived; But what should I doe? I had observed my maisters whose method I intended to follow, alwaies to doe the like; who thought themselves singularly well appointed to stanch a flux of blood, when they were furnished with various store of Hot Irons and causticke medicines, which they would use to the dismembred part, now one, then another, as they themselves thought meete. Which thing cannot be spoken, or but thought upon without great horror, much lesse acted. For this kinde of remedy could not but bring great and tormenting paine to the patient, seeing such fresh wounds made in the quicke and sound flesh are endewed with exquisite sence. Neither can any causticke be applyed to nervous bodies, but that this horrid impression of the fire will be presently communicated to the inward parts, whence horrid symptomes ensue, and oft times death it selfe. And verily of such as were burnt, the third part scarce ever recovered, and that with much adoe, for that combust wounds difficultly come to cicatrization; for by this burning are caused cruell paines, whence a Fever, Convulsion, and oft times other accidents worse than these. Adde hereunto, that when the eschar fell away, oft times a new hæmorrhagye ensued, for stanching whereof they were forced to use other causticke and burning Instruments. Neither did these good men know any other course; so by this repetition there was great losse and waste made of the fleshy and nervous substance of the part. Through which occasion the bones were laid bare, whence many were out of hope of cicatrization, being forced for the remainder of their wretched life to carry about an ulcer upon that part which was dismembred; which also tooke away the oportunitie of fitting or putting too of an artificiall legge or arme in stead of that which was taken off.

Wherefore I must earnestly entreate all Chirurgions, that leaving this old, and too too cruell way of healing, they would embrace this new, which I thinke was taught

taught mee by the speciall favour of the sacred Deitie; for I learnt it not of my mai-
sters, nor of any other, neither have I at any time found it used by any. Onely I
have read in *Galen*, that there was no speedier remedy for stanching of blood, than Lib. 5. Meth.
to bind the vessels through which it flowed towards their rootes, to wit, the Liver
and Heart.

This precept of *Galen*, of binding and sowing the Veines and Arteries in the new
wounds, when as I thought it might be drawne to these which are made by the am-
putation of members, I attempted it in many; yet so that at first in my budding
practise thereof, I alwayes had my cauteries and hot Irons in a readinesse, that if any
thing happened otherwise then I expected in this my new worke, I might fetch suc-
cour from the ancient practise, untill at length confirmed by the happy experience
of almost an infinite number of particulars, I bid eternally adieu, to all hot Irons and
cauteries which were commonly used in this worke. And I thinke it fit that Chi-
rurgions doe the like. For antiquity and custome in such things as are performed
by Art, ought not to have any sway, authority or place contrary to reason, as they
oft times have in civill affaires; wherefore let no man say unto us, that the Ancients
have alway done thus.

CHAP. XXV.

*The practice of the former precepts is declared, together with a memorable
history of a certaine soldier, whose arme was taken
off at the Elbow.*

Thinke it fit to confirme by an example the prescribed method of cu-
ring a Gangrene and Mortification. Whilest I was Chirurgion to the
Marshall of *Montejan* at *Turin*, a certaine common souldier received a
wound on his wrett with a musket bullet, by which the bones and ten-
dons being much broken, and the nervous bodyes cruelly torne, there followed a
Gangrene, & at length a mortification even to the Elbow; besides also an inflammati-
on seized upon the middle part of his Chest, and there was as it were a certaine dis-
position to a Gangrene, whereby it followed that he was painefully and dange-
rously troubled with belchings, hickettings, watchings, unquietnesse and frequent
sfoundings, which occasioned many Chirurgions to leave him as desperate. But it so
it fell out, that I orecome by his friends intreaty, undertooke the cure of this
wretched person, destitute of all humane helpe. Wherefore knowing the mortifi-
cation by its signes, I cut off the arme by the elbow as speedily as I could, making first
the ligature, where of I made mention; I say I tooke it off not with a saw, but onely
with an incision knife, cutting in sunder the ligaments which held the bones toge-
ther, because the sphacell was not passed the joynt of the Elbow. Neither ought
this section to be accounted strange, which is made in a joynt; for *Hippocrates*
much commends it, and saith that it is easily healed, and that there is nothing to be
feared therein besides sfoundings, by reason of the paine caused by cutting the com-
montendons and ligaments. But such incision being made, the former Ligature
could not hinder, but much blood must flow from thence, by reason of the large
vessels that run that way. Wherefore I let the blood to flow plentifully so to dis-
burden the part, and so afterwards to free it from the danger and feare of inflam-
mation and a Gangrene; then presently I stanchd the blood with an hot Iron, for as
yet I knew no other course. Then gently loosng the Ligature I scarifie that part
of the brawn of the Arme which was Gangreenated, with many and deepe incisions,
flanning and not touching the inner part, by reason of the multitude of the large
vessels and Nerves which runne that way; then I presently applyed a cautery to
some of the incisions, both to stanch the bleeding, and draw forth the virulent sanies
which

A History:

Dismembring
at a joynt.Sec. 4. lib.
de Art.

which remained in the part. And then I assailed and overcame the spreading putrefaction by putting and applying the formerly prescribed medicines; I used all sorts of restrictive medicines, to stay the inflammation of the Chest; I also applied Epithema's to the region of the heart, and gave him cordiall potions and boles, neither did I desist from using them untill such time as his belching, hicketing and swoonings had left him. Whilst I more attentively intended these things, another mischeife assailes my patient, to wit, Convulsions, and that not through any fault of him or me, but by the naughtinesse of the place wherein hee lay, which was in a Barne every where full of chinkes and open on every side, and then also it was in the midst of winter raging with frost and snaw and all sorts of cold; neyther had he any fire or other thing necessary for preservation of life, to lessen these injuries of the Aire and place; Now his joints were contracted, his teeth set, and his mouth and face were drawne awry, when as I pitying his case made him to bee carried into the neighbouring Stable which smoaked with much horse dung, and bringing in fire in two chafendishes, I presently annointed his necke and all the spine of his backe, shunning the parts of the Chest, with liniments formerly described for convulsions; then straight way I wrapped him in a warme linnen cloth, and buried him even to the necke in hot dung, putting a little fresh straw about him; when hee had stayed there some three dayes, having at length a gentle scowring or flux of his belly, and plentifull sweate, hee begun by little and little to open his mouth and teeth which before were set and close shut. Having got by this meanes some opportunitie better to doe my businesse, I opened his mouth as much as I pleased, by putting this following Instrument betweene his Teeth.

Burying in
hot horse dung
helpes Convulsions,

A Dilater made for to open the mouth and Teeth by the meanes of a screw in the end thereof.

Now drawing out the Instrument I kept his mouth open by putting in a willow sticke on each side thereof, that so I might the more easily feede him with meats soone made, as with Cowes milke and reare egges, untill hee had recovered power to eat, the convulsion having left him. Hee by this meanes freed from the Convulsion, I then againe begun the cure of his arme, and with an actuall cauterie seare the end of the bone, so to dry up the perpetuall afflux of corrupt matter.

It is not altogether unworthy of your knowledge, that hee said, how that hee was wondrously delighted by the application of such actuall cauteries, a certaine tickling running the whole length of the arme by reason of the gentle diffusion of the heate by applying the causticke; which same thing I have observed in many others; especially in such as lay upon the like occasion in the Hospitall of Paris. After this cauterizing there fell away many and large scalles of the bone, the freer appulse of the aire than was fit making much thereto; besides when

when there was place for fomentation, with the decoction of red Rose leaves, Wormewood, Sage, Bay leaves, flowers of Chamomile, Melilote, Dill; I so comforted the part that I also at the same time by the same meanes drew and tooke away the virulent *Sanies*, which firmly adhered to the flesh and bones.

A fomentation for a Convulsion.

Lastly, it came to passe, that by Gods assistance, these meanes I used, and my carefull diligence, he at length recovered. Wherefore I would admonish the young Chirurgion, that hee never account any so desperate, as to give him for lost, content to have let him goe with prognosticks; for as an ancient Doctor writes; That as in Nature, so in diseases there are also Monsters.

Monsters or miracles in diseases.

Ariscap. 6.
The internall
causes.*

The externall
causes.

Aving already handled and treated of the nature, differences, causes, signes and cure of fresh and blood wounds, reason & order seeme to require that we now speake of Vlcers; taking our beginning from the ambiguity of the name. For according to *Hippocrates*, the name of Vlcer most generally taken may signifie all or any solution of Continuity; In which sense it is read, that all paine is an Vlcer. Generally, for a wound and Vlcer properly so called; as appeares by his Booke, *de Vlceribus*. Properly, as when hee saith, it is a signe of death when an Vlcer is dried up through an *Atrophia*, or defect of nourishment. Wee have here determined to speake of an Vlcer in this last and proper signification. And according thereto wee define an Vlcer to bee the solution of Continuity in a soft part, and that not bloody, but sordide and unpure, flowing with quitture, *Sanies* or any such like corruption, associated with one or more affects against nature, which hinder the healing and agglutination thereof; or that we may give you it in fewer words according to *Galens* opinion; An ulcer is a solution of Continuity, caused by Erosion. The causes of Vlcers are either internall or externall. The internall are through the default of humors peccant in quality rather than in quantity, or else in both, and so making erosion in the skinn and softer parts by their acrimonie and malignitie; Now these things happen eyther by naughty and irregular diet, or by the ill disposition of the entrailes, sending forth and emptying into the habite of the body this their ill disposure. The externall causes are, the excesse of cold seazing upon any part, especially more remote from the fountaine of heate, whence followes paine, whereunto succeeds an attraction of humors and spirits into the part, and the corruption of these so drawne thither by reason of the debility or extinction of the native heate in that part, whence lastly ulceration proceeds. In this number of externall causes may be ranged, a stroake, contusion, the application of sharpe and acrid medicines, as causticks, burnes; as also impure contagion, as appeares by the virulent vlcers acquired by the filthy copulation or too familiar conversation of such as have the French disease. How many and what the differences of Vlcers are, you may see here described in this following Scheme.

A Table of the differences of Vlcers.

An Vlcer is an impure solution of continuity in a soft part, flowing with filth and matter or other corruption, whereof there are two chiefe differences, for one

Is simple and solitary without complication of any other affect against nature and this varies in differences, either

Of the signes of Vlcers.

The signes of
a putrid Vlcer.

Here are various signes of Vlcers according to their differences. For it is the signe of a putrid Vlcer, if it exhale a noysome, grievous, stinking and carion-like vapour, together with filthy matter. An eating Vlcer is knowne by the eating in, hollownesse and wearing away of the part wherein it resides, together with the adjoyning parts. A fardide Vlcer may be knowne by the grossnesse and visciduity of the excrements it sends forth, and by the loose and spongy softnesse, or the cruisted inequality of the flesh which growes over it. A cavernous Vlcer, by the streightnesse of the orifice, and largenesse and deepenesse of the windings within. A fistulous Vlcer, if to the last mentioned signes there accrew a callous hardnesse of the lips or sides of the Vlcer. A cancrus Vlcer is horrible to behold with the lips turned backe, hard and swollne, flowing with virulent and stinking corruption, and sometimes also with bloody matter, together with the swelling and lifting up of the adjacent veines. An untemperate, or as they terme it, a distempered Vlcer, is such as is nourished by some great distemper whether hot or cold, moist or dry, or compounded of these. An ill* natured or malignant Vlcer is knowne by the difficulty of curing and rebellious contumacy to remedies appointed according to art and reason. Wee know a catarrhus Vlcer, if the matter which feeds it flow to it from some *varices* thereunto adjoyning, or dilated, swollne and broken veines, or from some entrails, or from the whole body being ill affected. An Apostumatous Vlcer is perceived by the presence of any tumor against nature, whose kind may be found out by sight and handling. *Telephian* Vlcers, are such as affected *Telephus*, and *Chironian* (in whose cure *Chiron* excelled) are Vlcers which may be knowne by their magnitude not much putrid, and consequently not sending forth any ill smell, not eating, not tormenting with paine, but having their lips swollne and hard, and therefore ill to bee healed. For although they may bee sometimes cicatrized, yet it being but slender may easily bee broken, and the Vlcer renewed. They are almost like an ulcerated *Cancer*, but that they are accompanied with swelling in the adjacent parts; they are also worse than these which are termed *Cacoethe*, that is, ill natured or malignant; whence it is that *Fernelius* thought they had a hidden cause of malignitie, besides the common default of the humour, and that such as can scarce bee driven away; such commonly are left after the plague. Wherefore *Galen* thinks such to bee malignant as will not suppurate or yeeld any quittance.

Gal. cap. 7. lib. 4. Meth.
* *Vlcus cacoethe.*

Com. ad Aphor. 22. sect. 5.

CHAP. III.

Of the prognosticks of Vlcers.

Aph. 45. sect. 6.

He bone must necessarily scall, and hollow scarres be left by malignant Vlcers of a yeares continuance or longer, and rebellious to medicines fitly applied. The bone must scall by reason of the continuall afflux, and wearing by the acrimony of the humour, which looses the compostructure and glue by which the parts thereof are joyned together. But the scars must become hollow, for that the bone (whence all the flesh takes its first originall) or some portion thereof, being taken from under the flesh, as the foundation thereof, so much of the bulcke of the flesh must necessarily sinke downe, as the magnitude of the portion of the wasted bone comes unto.

Hip. progn. lib. 1. cap. 8.
Aph. 65. sect. 5.

You may know that death is at hand, when the Vlcers that arise in or before diseases, are suddenly either livid or dried, or pale and withered. For such driness sheweth the defect of nature, which is not able to send the familiar and accustomed nutriment to the part ulcerated. But the livid or pale colour is not onely an argu-
ment

ment of the overabundance of choler and melancholy, but also of the extinction of the native heate. In Vlcers where tumors appeare, the patients suffer no convulsions, neither are franticke; for the tumor being in the habite of the body possessed with an Vlcer, argues that the nervous parts and their originall are free from the noxious humors. But these tumors suddenly vanishing and without manifest cause, as without application of a discussing medicine, or bleeding, those who have them on their backs have convulsions and distensions, for that the spine of the backe is almost wholly nervous; but such as have them on their fore parts, become eyther franticke, or have a sharpe paine of their side, or pleurisie, or else a dysentery if the tumors be reddish; for the forepart of the body is replenished and overspread with many and large vessells, into whose passages the morbidicke matter being translated, is presently carried to these parts which are the seats of such diseases.

Soft and loose tumors in Vlcers are good, for they shew a mildnesse and gentleness of the humors, but crude and hard swellings are naught; for all digestion in some measure resembles elixation. Vlcers which are smooth and shining are ill, for they shew that there resides an humour maligne by its acrimony, which frets asunder the roots of the haire, and depraves the naturall construction of the pores of the skin; whence it is that such as are troubled with Quartaine agues, the Leprosie or *Lues venerea*, have their haire fall off.

Aph. 67. sect. 5.

Aph. 4. sect. 6.

A livid flesh is ill in Vlcers which cause a rottennesse or corruption of the bones lying under the flesh; for it is an argument of the dying heate and corruption of the bone, whence the flesh hath its originall and integrity.

These Vlcers which happen by occasion of any disease, as a Dropsy, are hard to be cured; as also those whereinto a *varix* or swollne vessell continually casts in matter, which a present distemper foment; which have swollne, hard and callous lips; and such as are circular or round. An *Hyperfarcosis*, or fleshy excrescence usually happens to Vlcers not diligently mundified; and if they possesse the armes or Legs they cause a Phlegmon or some other tumor in the groines, chiefly if the body bee full of ill humors, as *Avicen* hath noted. For these parts by reason of their rarity and weakenesse are fit and subject to defluxions. *Albucrasis* writes that for nine causes Vlcers are difficultly replenished with flesh and cicatrized. The first for want of blood, in a bloodlesse body; the second by reason of ill humors and the impurity of the blood; the third by the unfit application of inconvenient medicines; the fourth by reason of the fordidnesse of the Vlcer; the fifth by the putrification of the soft and carionlike flesh encompassing the Vlcer; the sixth when they take their originall from a common cause which every where rages with fury, such as are those which are left by the pestilence; the seaventh by reason of the callous hardnesse of the lips of the Vlcer. The eighth when the heavens and aire are of such condition as ministers fuell to the continuance of the Vlcer, as at Saragoza in Aragon; the ninth when the bones which lye under it are wasted by rottennesse.

Hip. lib. de ulc. Gal. cap. 2. 830 5. lib. Meth. 4.

For what causes Vlcers are hard to beale.

An Vlcer that casts forth white, smooth, equall quitture, and little or no stinking, is easily healed; for it argues the victory of the native heate, and the integrity of the solid parts. We terme that smooth quitture which is absolutely concocted, neither yeelds any asperity to the touch, whereby we might suspect that as yet any portion of the humor remaines crude; we call that equall wherein you can note no diversity of parts; and white not that which is perfectly so, but that which is of an ash colour, as *Galen* observes. But it is ill, if when the cure is indifferently forward, a fluxe of blood suddainly breake forth in those Vlcers which beate strongly by reason of the great inflammation adjoynd therewith. For as *Hippocrates* observes, an effusion of blood happening upon a strong pulsation in Vlcers is evill; for the blood breaking out of an Artery cannot be stayed but by force; and also this blood is so furious by reason of the heate and inflammation the nourishers of this Vlcer, that it breakes its receptacles, and hence ensues the extinction of the native heate, whence the defect of suppuration and a Gangrene ensues. Now for that there flowes two sorts of excrements from malignant Vlcers, the more thinne is tearmed *Ichor* or *saniès*, but the more grosse is named *sordes*; that is virulent and flowes from pricked nerves, and the *Periostia* when they are evill affected; but the other usually flowes from the

What pus or matter is smooth, equall and white.

Ad feulent. 3 2. sect. 2. de fract.

Aph. 21. sect. 7.

Two sorts of excrements flow from a malignant Vlcers.

Vlcers of the joynts, and it is the worser if it be blacke, reddish, ash-coloured, if muddy or unæquall like wine Lees, if it stinke. *Sanies* is like the water wherein flesh hath beene washed; it argues the preternaturall heate of the part, but when it is pale coloured, it is said to shew the extinction of the heate.

CHAP. IIII.

Of the generall cure of Vlcers.

The curing of
a simple Vlc
consists in ex-
siccation.

Gal. 7. Meth.
cap. 12.

Gal Lib. 4.
de comp. med.
secund. gen.

IN Vlcer is eyther simple or compound. A simple Vlcer, as an Vlcer hath one and that a simple indication, that is, exsiccation; and that more than in a wound, by how much an Vlcer is moister than a wound. There are many indications proposed for the cure of a compound Vlcer, in respect of w^{ch} *Galen* would have us to keepe this order, that wee have the first regard of the most urgent, then of the cause, then of that, which unlesse it be taken away, the Vlcer cannot be healed. By giving you an example you may easily understand the meaning hereof. Imagine on the inside of the Leg a little above the ancle, an Vlcer very painefull, hollow, putride, associated with the rottennesse of the bone, circular, having hard and swolne Lips, and engirt with the inflammation and *varices* of the neighbouring parts. If you take this to cure before you doe any thing about the Vlcer, unlesse you bee called upon by that which urges, as by vehemency of paine, you must first use generall meanes by calling and advising with a Physition; For in *Galens* opinion, if the whole body require a preparation, then must that be done in the first place; for in some Vlcers purgation onely will bee sufficient; in some bloodletting; others are better by using both meanes, which is as the cause of the Vlcer proceedes from a repletion or illnesse of humors. Now by these meanes having taken away the cause of the Vlcer, you must come to the particular cure thereof, beginning with that which is most urgent. Wherefore you must first assuage the paine by application of things contrary to the cause thereof, as if it proceede from a Phlegmonous distemper, which hath long possest, distended and hardened the part, it must bee eased by evacuation. First, bathing it with warme water, to mollifie and relaxe the skinne, that so you may the more easily evacuate the contained humors; then shall you draw away portion of the matter causing the swelling and paine by scarification, if the patient shall be of sufficient courage, or else by application of hose-leaches if hee be more faint hearted; and then you shall temper the heate there of by applying *Vnguentum refrigerans Galeni*.

To conclude, you shall attempt all things which wee have formerly delivered (in our treatise of Tumors) to take away the swelling thereof. When you have brought this to that passe you desire, you shall come to those which are such, that it cannot be taken away or healed without them, which shall be done by orderly helping the defects against nature which were conjoynd with the Vlcer, to wit, the rottennesse of the bone, which you shall helpe by actuall cauterics; and in the meane while you shall draw the Vlcer into another forme, to wit, cornered, and you shall cut away the callous hardnesse, and helpe the rottennesse. Then must you procure the falling away of the Eschar, and then provide for the scailing of the bone by the meanes formerly prescribed, lastly the mundified Vlcer must be filled with flesh.

The things
conducing to
the generating
of flesh.

For generating of flesh two causes must concurre, the efficient and materiall; The efficient is, the good temper both of the whole body, as also of the Vlcerrated part. For this prevailing, there will be an attraction, digestion, apposition and assimilation of the laudible juice to the part affected; verily the laudible temper is preserved by like things, but the vicious is amended by contraries. The matter to bee spent upon flesh, is laudible blood, which offends neither in quality, nor quantity. In this regeneration of the flesh there appeare two kinds of excrements, the one more thinne and humide called *Sanies*, the other more grosse termed *Sordes*. Both of these for that they are contrary to nature, doe therefore hinder the regeneration of flesh, and therefore must be taken away by applying their contraryes, as by things drying

drying in the first degree, and more strongly or weakly detergent according to the complexion of the part and the whole body, and the plenty and quality of the excrementitious humor, and the uncleanness of the Vlcer. For the part must be preserved by the use of the like, but the ulcer overcome by application of things contrary thereto. After that by natures endeavour and the Chirurgions helpe the Vlcer is replete with flesh, it must be cicatrized, that is, covered with a callous skin in stead of the true and native skin. It may be cicatrized by strewing of very drying pouders having very little or no acrimony. Thus Alume and vitrioll being burnt and made into powder, and thinly strewed upon the part doe quickly cicatrize the former fleshy worke. To this purpose also serve, the roote of *Aristolochia*, Aloes, burnt Lead, Pomegranat pills burnt, Litharge, *Tutia*, and also plates of Lead besmeared with quicksilver, whose efficacy for this purpose Chirurgions sometimes finde more certaine and powerfull than any other remedies.

What a Scarre is.

Things causing cicatrization.

CHAP. V. Of a distempered Vlcer.

BEfore we speake of a distempered Vlcer, it is meete, least that the Chirur-
gion take one distemper for another, briefly to relate the signes of each. You may know that an Vlcer is associated with a dry distemper by your sight, as if the Vlcer be as it were wrinckled, if it send forth little or no moisture; also it is knowne by touch, if it feele rough and hard. You shall correct this distemper by humecting medicines, as fomenting it with warme water according to *Galen's* opinion, or else with *Hydrasum* (i. e.) Oile and water mixt, but alwayes you must first purge, if the body shall abound with ill humors, or use Phlebotomie if the body be plethoricke; otherwise you shall draw more humors into the part than it can beare. Now you shall so long foment it, untill the flesh which is about it begin to looke red, was soft and moist, and the part it selfe be a little swollne. If you proceede further, you will resolve all the humor which you have drawne thither, and so your labour is in vaine. After the fomentation apply such a remedy to the ulcerated part.

R. cremoris hordei ʒij. fol. malva in aq. coct. ʒj. pingued. porci ʒss. mellis com. ʒss. misce in mortario & fiat unguentum.

Signes of a distempered Vlcer.

Remedies for a dry distempered Vlcer.

You shall know a moist distemper associates the Vlcer by the plenty of the excrementitious humor, which the Vlcer sends forth; by the spongie and fungous softnesse and growth of the flesh about it. You shall amend this by drying remedies, such as these are, which we terme sarcoticks, having alwayes regard to the plenty of the humour, the proper temper of the part, and other indications formerly mentioned. Amongst other remedies *Galen* much commends Alume water, for it dries, clenches and corroborates the affected part. Also this ensuing fomentation may be applied to good purpose. *ʒ. rosar. rub. absinth. beton. tapsi barbat. an. m. j. gallarum, nucum cupressi, an. ʒij. aluminis rocha ʒj. fiat decoctio in vino austero, instituatur fons;* Then let *Empl. de cerussa* or *De minio* be applyed to the Vlcer. Also I have found by experience that the powder of burnt alome lightly strewed upon the Vlcer is very effectuell in this case. You shall know that an hot distemper associates the Vlcer by rednesse, or yellownesse thereof, by the heate manifest to your touch, and the propriety of the paine. Then must you have recourse to refrigerating things, such a *ung. Rosatum M. f. Refrigerans Gal. Populeon*; stoopes and cloathed dipped in plantaine water, Night shade water, or Oxycrate. I have oft found by experience that scarification, or Leaches being applyed, did more conduce than any other remedy. For so the chafed blood, which by that meanes is apt to corrupt, is drawne away, and the part its selfe is also freed of that burden.

Signes of too moist an Vlcer.

Gal. lib. 1. simp. cap 7.

Signes of a hot distempered Vlcer.

We know a cold distemper by the whitish or pale colour, by the touch of the Chirur-
gion, and speech of the patient complaining of the coldnesse of the ulcerated part. You shall correct this by applying and putting bottles filled with water about the part, or else Swines bladders halfe filled with the following decoction.

Signes of a cold distempered Vlcer.

ʒ. origani, pulegy, chamam. melilori, an. m. j. absinth. majorana, salvia, rorismar. an. m. ss. fiat

fiat decoctio in vino generoso, addendo aqua vite quod sufficit. Also the Vlcer may conveniently be fomented with sponges dipped in the same decoction, and let there be applied thereto *Empl. Oxycroceum; emp. de meliloto; de Vigo cum mercurio, and sine mercurio.* But if a mixt and compound distemper be joynd to the Vlcer, the medicines must in like manner be mixt & composd. The residue of the Chirurgical care and paines must be spent upon the proper and peculiar cure of the Vlcer, as it is an Vlcer; which we said in the former Chapter was contained in deterfion, regenerating flesh and cicatrization thereof.

CHAP. VI.

Of an Vlcer with paine.

The matter
of Narcoticke
cataplasmes.

Catheracticks
have power to
assuage paine.

Here oft times so great paine accompanieth Vlcers, that it calls thereto the counsell of the Physician. Wherefore if it proceede from any distemper, it shall be taken away by remedies proper against that distemper, such as we mentioned in the former Chapter. But if it doe not so cease, wee must goe on to Narcoticks. Such are cataplasmes of the leaves of Mandrakes, water lillies, Henbane, Nightshade, Hemlocke, the seeds of Poppy and Oyles of the same; to which also may be added *Opium, Populeon*, and other things of like faculties. But if a malignant acrimonie and virulency of an humour corroding and eating the flesh lying under it and the lips about it, cause and make the paine, you shall neither assuage it by anodynes, nor Narcoticks; for by application of gentle medicines it wil become worse and worse. Wherefore you must betake you to Cathæreticks; For strong medicines are fittest for strong diseases. Wherefore let a pledget dipped in strong and more than ordinarily powerfull *Aegyptiacum*, or in a little oyle of Vitrioll, be applyed to the Vlcer; for these have power to tame this raging paine, and virulent humors. In the meane season let refrigerating things be put about the Vlcer, least the vehemency of acrid medicines cause a defluxion.

CHAP. VII.

Of Vlcers with overgrowing or proudnesse of flesh.

Things wash-
ing super-
fluous flesh.

Lib. 3. Meth.
cap. 6.

Vlcers.

Vlcers have oft times proud or overgrowing flesh in them, either by the negligence of the Chirurgion, or fault of the patient. Against this, drying and gently eating or consuming medicines must be applyed; such as are Galls, *cortex thuris*, Aloes, *Tutia*, Antimony, *Pompholix*, Vitrioll, Lead, all of them burnt and washt if neede require. Of these powders you may also make ointments with a little oyle and waxe; but if the proud flesh, as that which is hard and dense yecld not to these remedies, we must come to causticks, or else to iron, so to cut it off. For in *Galens* opinion, the taking away of proud flesh is no worke of nature, (as the generating, restoring and agglutinating of the flesh is) but it is performed by medicines which dry vehemently, or else by the hand of the Chirurgion; wherefore amongst the remedies fit for this operation, the powder of mercury with some small quantity of burnt Alum, or burnt Vitrioll alone, seeme very effectual to me. Now for the hard and callous lips of the Vlcer, they must be mollified with medicines which have such a faculty, as with Calves, Goose, Capons or Ducks grease, the oiles of Lillies, sweet Almonds, Wormes, Whelpes, *Oesipus*, the mucilages of Marsh-mallows, Linefeede, fanugreeke feede, Gum *Ammoniacum*, *Galbanum*, *Bdellium*, of which being mixed may be made Emplaisters, unguents, and liniments, or you shall use *Emp. Diachylon*, or *de Mucaginibus*, *De Vigo cum mercurio*. To conclude, after we have for some few dayes used such like remedies, you may apply to the Vlcer a plate of Lead rubbed over with Quicksilver; for this is very effectual to smooth an Vlcer and depresse the lips; if you shall prevaile nothing by this meanes, you must come to the causticks, by which if you still prevaile nothing, for that the lips of the Vlcer are so callous that the caustickes cannot perce into them, you must cleave them with a gentle scarification, or else cut them to the quicke, so to make way,

or

or as it were open a window for the medicine to enter in, according to *Galen*. Neither in the interim must you omit *Hippocrates* his advice, which is, that by the same operation we reduce the ulcer if round, into another figure, to wit, long or triangular. Lib 4. Meth, cap. 2.

CHAP. VIII.

Of an Ulcer putride and breeding wormes.

Ormes are divers times bred in ulcers, whence they are called wormie ulcers; the cause hereof is the too great excrementitious humidity prepared to putrefie by unnaturall and immoderate heate. Which happens, either for that the ulcer is neglected, or else by reason of the distemper and depraved humors of all the body, or the affected part; or else for that the excrementitious humor collected in the ulcer, hath not open and free passage forth; as it happens to the ulcers of the eares, nose, fundament, necke of the wombe, and lastly to all sinuous and cuniculous ulcers. Yet it doth not necessarily follow that ali putrid ulcers must have wormes in them; as you may perceiue by the definition of a putride ulcer which we gave you before. For the cure of such ulcers after generall meanes, the wormes must first be taken forth, then the excrementitious humor must be drawne away, whence they take their originall. Therefore you shall foment the ulcer with the ensuing decoction, which is of force to kill them; for if any labour to take forth all that are quicke he will be much deceived; for they oft times doe so tenaciously adhere to the ulcerated part, that you cannot plucke them away without much force and paine.

The cause of wormes breed in Vlcers.

R. absinth. centaur. majoris, marrubij, an. M. j. fiat decoctio ad lb. ss. in qua dissolve aloes ꝑb. unguenti aegyptiaci ꝑj. Let the ulcer be fomented and washed with this medicine, and let pledgets dipped herein be put into the ulcer; or else if the ulcer be cuniculous or full of windings, make injection therewith which may goe into all parts thereof.

A fomentation to kill the wormes.

Archigenes much commendeth this following medicine. *R. Cerusa, polij montani, an. ꝑb. picis navalis liquida quantum sufficit, misce in mortario pro linimento.* If the putrefaction be such that these medicines will not suffice for the amendment thereof, you must come to more powerfull, or to cauteries also, or hot Irons, or to section; yet you must still beginne with the more gentle, such as this of *Galen*'s description.

Gal. 4. comp. med.

R. cera. ꝑj. cerusa ꝑj. olei ros. ꝑj. salis ammon. ꝑb squam. aris ꝑij. thur. alum. arag. malicer. calcis viva, an. ꝑj. fiat emplastrum. Or *R. terebinth. lota ꝑj. cera alba ꝑb liquefiant simul addendo sublimati, ꝑb. salis torrefacti, & vitrioli calcinati, an. ꝑj. fiat mundificatorium.* Or you must use our *Aegyptiacum* alone, which hath Sublimate entring into the composition thereof; but in the interim the circuit of the Ulcer must be defended with refrigerating, and defensative things for feare of paine.

CHAP. IX.

Of a sordide Vlcer.

Sordide Vlcer after the cure of the body in generall, shall be healed with detergent medicines; the indication being drawne from the grosse and tough excrement, which with the excrementitious *Sanies*, as it were besieging, and blocking up the ulcerated parts, weakens and as it were dulls the force of medicines though powerfull, which causeth us to beginne the cure with fomentations and lotions as thus.

R. Lixivij com. lb. j. absinth. marrub. appj. centaur. utriusque, hypericonis, an. M. ss. coquantur, colatura, qua sufficiat, adde mellis rosati ꝑj. unguenti aegyptiaci ꝑb. fiat lotio. Then use the following deterfive medicine: *R. succi appj. & plantag. an. ꝑj. mellis com. ꝑj. terebinth. ꝑb. pul. areos Florent. & aloes, an. ꝑb. fiat medicamentum.*

A detergent lotion.

The Chirurghion must wel consider, at how many dressings he shall be able to wash

Detergent medicines without acrimony.

A caution very observable in use of detergent things.

A distinction to be observed concerning the impurity of ulcers.

Diligent regard must be had of the patients bodies and the affected parts.

away the grosse *sordes* or filth sticking close to the Vlcer, and dry up the excrementitious *sanies*. For oft times these things may be done at one dressing; but in others who have more quicke sense or feeling, not so soone. But when the Vlcer is freed of such grosse *Sordes* or filth, you must forbear to use more acride things for feare of paine, defluxion, inflammation, and erosion, whereby the Vlcer would become more hollow. Wherefore then we shall bee content to apply remedies which dry and cleanse without acrimony, that wee may so helpe natures endeavours in generating flesh. Such remedies are the pouders of Aloes, Mastich, Myrrhe, Orris, Litharge, Antimony, roots of Gentian, Barly flower, and the like, which being strewed upon the Vlcer, you shall cover it with Lint, and put over that a plate of Lead, rubbed over with quicksilver; and you shall put on these deterfives and desiccatives more or lesse strong, as you shall finde it requisite and necessary. For the too plentiful use of drying and deterfiv things, doth in time hollow the Vlcers, whereby it comes to passe that in short time in like sort, a greater quantity of *Sanies* flowes from the Vlcer, the proper substance of the flesh being dissolved by the force or acrimony of the deterfiv medicine; as also the proper alimentary humor, which flowed to the part, being in like sort, a greater quantity of *Sanies* flowed from the Vlcer, the proper substance of the flesh being dissolved by the force or acrimony of the deterfiv medicine, as also the proper alimentary humor, which flowed to the part, being in like sort defiled: which thing beguiles the unskilfull Chirurgion. For by how much he sees the Vlcer flow more plentifully with *sanies*, he endeavours by so much the more to exhaust and dry up with more acrid medicines these humidities as if they were excrementitious; But *Galen* hath long agoe admonished us to take heede hercof, setting forth a History of a certaine Empericke who dressing a sordide Vlcer with a greene, acrid and eating medicine, dissolved the flesh, and so consequently made the Vlcer more hollow, and caused more paine and defluxion; whereby it happened that continually adding more acrid medicines, hee continually by his ignorance and unskilfulnesse increased the colliquation of the flesh, the largenesse of the ulcer and excrementitious humidity. Wherefore wee must take speciall care, whether the sordide Vlcer grow each day worse, by its proper fault and the impurity of the whole body besides, or else by the colliquation of the flesh and corruption of the benigne and alimentary humor sent thither for the nutrition of the part, by the too frequent and unskilfull use of too acrid a medicine. You may conjecture this by the increase of the paine without reason, and by the heate and rednesse of the lips of the Vlcer. Therefore you must principally have regard to this, that you give each of your patients his fit measure, that is, a convenient and agreeable medicine to each of their strengths, taking indication from the strength, distemper, and consistence of the whole body and affected part; for there is a great deale of difference whether you apply a medicine to a plowman or labourer, or to an Eunuch and woman, or whether to the Legge, or eyes. For these medicines which to a dense and hard body and part are onely detergent and drying, the same are to delicate and tender bodies and parts cathæreticke and eating, by colliquation of the flesh, and corruption of the nourishment, making an increase of *Sordes* or filth; on the contrary those things which doe laudibly and sufficiently cleanse the flesh in a soft body and dry up the *sanies*, these same things applied to a hard body increase the *sordes* and *sanies* by suffering them to breed, neither are they of sufficient power to wash away the tenacious impurity of a dense body. Wherefore the skilfull Chirurgion will see when he must betake himselfe from too strongly cleansing and eating medicines, to these which are more milde.

CHAP. X.

Of a virulent, eating & malignant Vlcer which is termed Cacoëthes, & of a Chironian Vlcer.

How virulent and eating ulcers differ.

Virulent and eating Vlcers differ not unlesse in *magis* and *minus*, for we tearme it a virulent Vlcer which sends forth a virulent *sanies*, which is properly called *Virus*. This *Virus*, or virulency, when it becomes more malignant, gnawes

gnawes and feeds upon the parts which lye under, and are adjoyning to the Vlcer, and makes an eating Vlcer. Such Vlcers are by *Galen* called *Dyssepulotica*, that is, difficultly to be cicatrized; for, saith he, it happens that the Vlcer is *Dyssepuloticke*, either for that the part affected may be vitiated either in the habit or temper thereof, so that it may corrupt the humor which flowes thither; such an Vlcer is by a particular name tearmed *Cacoethes*; or for that by reason of the evill quality of the blood flowing thither and eating the part, the part affected being too moist cannot heale up. He further addes that a Chironian Vlcer is farre more maligne than these Vlcers which are tearmed *Cacoethe*.

Gal. Lib. 4. de comp. med. sec. genera.

How a chironian ulcer differs from an eating, see before, Cap. 25

For the cure; by reason that all these Vlcers have a large extent, for some are more maligne and ill to be cicatrized than othersome; it is also necessary to have divers medicines ready and at hand distinct both in their faculties and the degrees thereof; so that it is no marvaile if they oft faile of their purpose, who with the same medicine dresse and thinke they shall heale all maligne Vlcers. This following medicine described by *Asclepiades* is much commended by *Galen*.

℞. squama aris, aruginis rase, an. ʒij. cera lb. ss. resine laricis. ʒjss. qua liquari possunt aridis affundantur, and make an emplaister to bee laid onely upon the Vlcer; for you must lay a defensative about the Vlcer for feare of inflammation. But *Galen* saith, that the following Epuloticke of *Primion* excells the rest, as that which to desperate Vlcers, (which many have taken in hand and left as incurable,) was of certaine and approved use.

Gal. lib. 4. sec. gen. Cap. 55

℞. sorcos ʒij. aluminis scissilis, calcis viue, an ʒij. thuris, gallarum, an. ʒiij. cera, lb. j. & ʒiij. seu vitulini lb. j. & ʒviij. olei veteris quantum sufficit, fiat emplastrum.

Gal. lib. 3. de comp. med. sec. gen. Cap. 65

CHAP. XI.

An advertisement to the young Chirurgion touching the distance of times wherein maligne Vlcers are to be dressed.

O shew the use of *Asclepiades* his medicine described in the former Chapter, and convince the error of these Chirurgions, who thinke they doe well for their patients, if they twise or thrice on a day dresse maligne Vlcers, I have beere thought good to digresse a little from my purpose and to interpolate *Galen's* authority. Rightly (saith *Galen*) hath *Asclepiades* added these words to the formerly described medicine: And loose this after three dayes, and foment the Vlcer, and fasten the same emplaister being washed, and apply it againe; for unlesse the medicine adhere long to the skin, it will doe no good. Which thing notwithstanding many Physicians have beene ignorant of, thinking if they wiped away the *Sanies* from the Vlcer thrice on a day, they should doe better than those who did the same but twice a day. But those who dresse it but once a day, are reprooved by the patients as negligent. But they are much mistaken; for you must remember, as we have delivered in most of our writings, that the qualities of all neighbouring bodies do mutuall actuate and affect each other in some degree, although the one thereof bee much more powerfull; for by this reason in space of time they become somewhat alike, though they otherwise differ much; But when the quality of the medicine shall bee like in *species* to the body to bee cured, there followes the better successe. Wherefore he which moved by these reasons first appointed to use the emplaister formerly applyed, is worthy of commendations; and we ought to follow him much the rather, seeing that which he found out by reason, is approved by experience. Neither did he unadvisedly command to foment the wound every third day, that is, at every dressing; for seeing it is a powerfull medicine, therefore it stands in neede of mitigation. Thus much *Galen*, whose opinion grounded on reason, he can againe confirme with another reason. It is already sufficiently knowne, that medicines can doe nothing in us unlesse by the force of the native heate, which stirres up the faculty of the medicine to operation. But in Vlcers which are absolutely maligne, the native heate of the affected part is very languid, being broken

Gal. lib. 4. de comp. med. sec. gen. Cap. 55

Galen's reason further explained,

broken and debilitated by the presence of the preternaturall heate; so that it stands in need of a great space of time to actuate the vertue and faculty of the medicine. Wherefore, if in that time, when as the native heate hath much moved and stirred up the faculty of the medicine, the ulcer be loosed or opened, and that emplaister cast away which was layd upon the part, and a fresh one layd in steede thereof, the heate implanted in the part is either dissipated by the contact of the ayre, or is weakned and driven in; and that endeavour which was made by the emplaister was to no purpose, being as it were stopped in the midst of the course. But a new emplaister being layd on, the heate of the part must undergoe a new labour, so to stirre up the faculty to bring it to act.

Medicines are
onely such in
faculty.

For all medicines are, what they are, in faculty. Equall to this is their error, who by too oft renewing their emplaisters on the same day, doe too powerfully clense; for so they doe not onely take away the excrementitious humors, both *Sordes* and *Sanies*, but also the alimentary juice; to wit, the *Rob*, *Cambium*, and *Gluten*, which are the next matter for procreating of laudible flesh. Wherefore it is not good to dreisse Vlcers so often in one day, and to loose them to apply new emplaisters, unlesse some grievous symptome (as paine) force us to doe it, which requires to be asswaged and mitigated by the often changing and renewing of Anodyne medicines.

CHAP. XII.

How to binde up Vlcers.

The beginnig
of your bind-
ing must be
at the Vlcere.

Hip. lib. de ale.

Revulsion into
contrary
parts.

Or the binding up of Vlcers, you must alwayes beginne your bandage at the Vlcere. Now the Rowler must be so large that it may not onely cover and comprehend the Vlcere, but also some portion of the adjacent parts above and below; and let it presse the Vlcere with that moderation, that it may only presse out the excrementitious humors. For so the ulcer wil become dry, and consequently more neere to healing, as it is observed by *Hippocrates*. Let this be the measure of your binding, that it be neither too strait for hence would ensue paine and defluxion; nor too laxe, for such is of no use. You may moysten your boulders and Rowlers in oxycrate or in red and astringent wine, especially in Summer; when you have bound it up the part must be kept quiet. For according to *Hippocrates*, those who have an ulcer in the legges, ought neither to stand, nor sit, but to lye on a bed. Wherefore when the legges are ulcerated the armes must be exercised, by handling, lifting up and casting downe of divers things. But on the contrary if the armes be ulcerated, the legges must be exercised with walking, or frictions from above downewards, if the patient cannot endure to walke. So the humors and spirits which with more violence and greater plenty runne downe to the part affected, may be drawne backe and diverted.

CHAP. XIII.

Of the cure of particular ulcers, and first of those of the eyes.

4. Methodi.

Or that (in *Galen's* opinion) the diverse indication in curing diseases is drawne from the condition of the part, to wit, the temper, complexion, site, figure, use, dull or quicke sense; Therefore having breecely handled the generall cure both of simple and compound and implicate ulcers, I thinke it fit to treat of them now as they are distinguished by the parts, beginning with these of the eyes. These according to *Celsus*, are sometimes caused by pustules, or a sharpe defluxion which frets or eates in sunder the coates thereof, or else by a stroake.

Lib. 6. cap. 6.
lib. 3.
Botryon.
Caloma.

Paulus sets downe these differences of the ulcers of the eyes; If (saith he) a small, little and hollow ulcer be upon the horny coate, it is by the Greekes termed *Botryon*; but if it be broader and lesse deepe, it is termed *Caloma*; about the circle of the *Iris* or

Raine-

Rainebow, it is called *Argemon*. If it be crusty and sordid, it is termed *Epicauma*. These in generall require the same cure as the former, that is, to bee mundified, incarnated, dried and cicatrized; but the part affected indicates more gentle medicines. Wherefore having purged the patient and taken some blood both from his arme, as also from his veines and temporall Arteries, and bathed him if it be needfull; to divert the defluxion you shall to his shoulders apply cupping glasses with scarification; or else bread newly drawne out of the oven, and sprinkled with *aqua vita* or some good wine shall be applyed to the originall of the spinall marrow. But you shall apply to the forehead and temples an astringent emplaister made of *emplastrum contra rupturam*, *arg. Comitise*, and *Resiccativum rubrum* mixed together. But this ensuing *Collyrium* described by *Celsus* and approved by *Hollerius*, shall be dropped into the eye. *R. aris usti, cadmia usta & lota, an. ʒj. ex aqua fingatur collyrium quod liquore ovi dissolvatur.* But in the meantime you must diligently observe whetheryou put the eye to any great paine. Wherefore now and then by putting anodyne medicines thereto, it will be good to comfort it. Also you may make *collyria* of the decoction of Plantaine, fenugreeke, wormewood, with a little quantity of Sugar Candy, *tutia*, gumme *tragacanth*, myrrhe and vitmoll dissolved therein. When the ulcer is mundified, the following sarcoticke will be of good use.

Argemon.
Epicauma.
The cure

A *Collyrium*
to cleanse the
Vlcers of the
eyes.

R. sarcocolla in lacte muliebri nutrita, ʒiij. pul. diatreos simplicis, gum. arabici, tragacanth, an. ʒʒ. mucilaginis sanugraci quantum sufficit ut inde fiat collyrium. But you must note that for moyst Vicers, powders are more convenient than *Collyria*.

A sarcoticke
Collyrium.

When the ulcer is playned or filled with its proper flesh, it may bee cicatrized with the following *collyrium*. *R. tutia, cadmia ut decet preparata, cerusa, antimony, olivani, an ʒʒ. myrrha, sarcocolla, sanguinis Draconis, aloes, ʒij, an. ʒʒ. cum aqua plantaginis fiat collyrium;* or the powder onely may be conveniently strewed thereon.

An epulotick
Collyrium.

Celsus hath noted that the cicatrizing of the eyes is incident to two dangers, that is, least they be too hollow, or else too thick. If too hollow, they must be filled by the following remedy, *R. Papaveris lachryma, ʒʒ. sagapeni, opopanax, an. ʒʒ. aruginis ʒj.*

Lib. 6. cap. 6.

cumini ʒiij. piperis ʒij. cadmia lota & cerusa, an. ʒʒ. cum aqua pluviali fiat collyrium.

A *Collyrium*
for hallow
scarres.

But if the scars be thicke or grosse, the following remedy will extenuate them. *R. cinamom. acacie, an. ʒʒ. cadmia elota, croci, myrrha, papaveris lachryma, gum. arabici, an. ʒj piperis albi, thuris, an. ʒʒ. aris combusti, ʒiij. cum aqua pluviali fiat collyrium.*

But if the scarre be upon the cornea or horny coate, so that it cover the pupilla or sight, the sight will be intercepted by the denseness of the membrane. Here you must also observe, that the scarres that are on the Cornea are white, but these on the Adnata are red, because this is spread over with more little veines than that.

The scarres of
the fleshy coate
are white and
these of the
Adnata red.

CHAP. XIII.

Of the Ozæna and Vicers of the Nose.

THe *Ozæna* is a deepe and stinking Vicer in the inside of the nose, sending forth many crusty and stinking excrements. *Celsus* saith that such ulcers can scarcely be healed. It is caused (as *Galen* saith) by the distillation of acride and putride humors from the head into the nosethrills about the mammillary processes. For the cure, the patient must eat sparingly, and his meate must neither be sharpe nor strong; the humor being prepared must be purged; the head dried and strengthened, that so it may neither admit the excrementitious humors, nor send them downe; then must we come to the part affected with the Vicer. The Vicer must be dried with a repelling medicine, such as is the juice of Pomegranats boyled to the halfe in a brasle vessell; the powder of Calamint, Cresses, white Hellebore, the juyce of Cresses with Alume and other things which you may reade in *Celsus*.

Lib. 6. cap. 8.
Ga. Lib. 3. de
comp. med.
secunda. ocos
cap. 3.
The cure.

Galen out of *Archigenes* wishes, to draw up into the nosethrills the juyce of Calamint, or that the Calamint it selfe being dried, and made into powder, may bee blowne with a quill into the nose. Others use this following powder. *R. ros. rab. mint.*

mint. calam. arom. rad. angelica. gentian. macis. caryop. an. ʒʒ. camph. ambræ. an. gr. iiii. mosch. gr. vj. fiat pulvis subtilissimus. Manardus writes that the Urine of an Asse, though a nasty medicine, is an excellent remedy in this affect. But if the inveterate and contumacious evill doe not yeeld to these remedies, then you must have recourse to Coprose, Verdigreece, *sal ammoniacum*, and Alume with Vinegar. It divers times happens that the Vlcer spreading on, comes to take hold of the *Ossa ethmoidæ* or five-like bones; in which case you must not forcibly plucke them out; but referre the whole businesse to nature, and expect when they shall come away of themselves, making in the meane while injections into the nozethrills of *aqua vitæ*, wherein Cephalicke powders have beene steeped for the greater drying.

An injection when the *Ozæna* shall come to the *Ossa Ethmoidæ*.

CHAP. XV.

Of the Vlcers of the mouth.

Aph. 24. sect. 3. Celsus lib. 6. cap. 11. Galen. com. ad 3. lib. eptæm.

Of this tribe are the *Aphthæ*, Vlcers familiar to little children, according to *Hippocrates*. They oft times beginne at the gums, and by the palate of the mouth creepe into the *uvula*, throtle, and over all the mouth, as *Celsus* saith. *Galen* makes two kinds of *Aphthæ*; the one of easie cure, such as that which usually troubles children by reason of the acrimony of the nurses milke; the other is maligne by reason of an afflux of an evill humor (that is, venenate and maligne) into the mouth.

The cure.

For the cure, it shall be good to abstaine from all acride things, and if it be a sucking child, it will not be amisse to temper the nurses milke with refrigerating meates, bathing the whole body, and fomenting the dugges with warme water; for all the members in children are most tender, and as it were mucous, and their mouths are unaccustomed to meates and drinckes. For topicke medicines, you must make choise of such which may quickly and readily worke the effect; for heere the condition of the affected part is such, that they cannot long remaine and adhere thereto. Therefore if the Vlcer be maligne, it must be lightly touched with *aqua fortis* which hath beene used in separating mettalls and which besides is tempered with sixe parts of common water. You may for the same purpose use the oyles of Vitrioll, Sulphur, Antimony, Mercurie water and the like.

Aetius wishes you to touch and correct such Vlcers with a Locke of wooll dipped in scalding oyle, and so fastened to the end of a probe, untill they waxe white and become smooth or plaine. For so their eating and spreading force will at length be bridled, and laudible flesh grow up in place of that which is eaten. After such burning it will be good to wash the mouth with the following gargarisme, which also of its selfe alone will serve to cure *Aphthæ*, which are not maligne.

A gargarisme for the *Aphthæ*.

Lib. 6. meth. Cap. 10.

Vlcers of the palate must be quickly and carefully dressed.

R. hordei integri p. j. plantag. ceterach. pilosella. agrimonia. an. M. j. fiat decoctio ad lb. j. in qua dissolve mellis rosati ʒi. diamoron, ʒʒ. fiat gargarisma. You may also make other gargles, of Pomegranate pills, Balausties, Sumach, Berberies, red roses being boyled, and dissolving in the strayned liquor *Diamoron* and *Dianuncum* with a little Alume. For *Galen* writes, that simple Vlcers of the mouth are healed with things which dry with moderation; now *Diamoron* and *Dianuncum* are such. But others stand in neede of strong medicines, with such like. If the palate be seized upon, we must use the more diligence and care; for there is danger, least being the part is hot and moist, the bone which lyes under which is rare and humide, may bee corrupted by the contagion and fall away, and the voyce or speech be spoyled. If the Vlcer be pockie, omitting the common remedies of Vlcers, you must speedily betake your selfe to the proper antidote of that disease, to wit, quick-silver.

Aetius lib. 6. cap. 3. Celsus lib. 6. cap. 13.

Fistulous Vlcers often take hold on the Gummies, whence the roote of the next tooth becomes rotten, and so farre that the acrimony of the *Sanies* oft times makes its selfe a passage forth on the outside under the chinne; which thing puts many into a false conceite of the *scrophula* or Kings evill, and consequently of an uncurable disease. In such a case *Aetius*, and *Celsus* counsell is, to take out the rotten tooth, for so

the

the *Fistula* will be taken away, the Gum pressing and thrusting its selfe into the place of the tooth which was taken forth; and so the cause nourishing the putrefaction being taken away, (that is, the tooth) the rest of the cure will be more easy. The Ulcers of the tongue may be cured by the same remedies by which the rest of the mouth; yet those which breede on the side thereof endure very long, and you must looke whether or no there be not some sharpe tooth over against it, which will not suffer the Ulcer in that place to heale; which if there be, then must you take it away with a file.

CHAP. XVI.

Of the Ulcers of the Eares.

Ulcers are bred in the auditory passage both by an externall cause, as a stroke, or fall, as also by an internall, as an abscesse there generated. They oft times flow with much matter, not there generated, for such Ulcers are usually but small and besides in a spermatike part, but for that the braine doth that way disburden its selfe.

Their causes

For the cure, the cheefe regard must be had of the antecedent cause, which feedes the Ulcer, and it must be diverted by purging medicines, Masticatories and Errhines.

The cure,

This is the forme of a Masticatory. ʒ. Mastice. ʒj. staphisagr. & pyreth. an. ʒj. cinam. & caryoph. an. ʒʒ. fiant Masticatoria, utatur mane & vespere.

A masticatory

But this is the forme of an Errhine. ʒ. succi betonice. mercurialis & melissa, an. ʒʒ. vini albi ʒj. misce & frequenter naribus attrahatur.

An Errhine.

For topicke medicines we must shunne all fatty and oily things, as *Galen* sets downe in *Method. medendi*, where he findes fault with a certaine follower of *Thessalus* who by using *Tetrapharmacum*, made the Ulcer in the eare grow each day more filthy than other, which *Galen* healed with the Trochisces of *Andronius* dissolved in Vinegar, whose composure is as followeth. ʒ. balaust. ʒij, alumin. ʒj. atrament. sutor. ʒij, myrrha. ʒj, thur. aristoloch. gallarum, an. ʒij, salis ammon. ʒj. exsicciantur omnia melicrato, & fiant trochisci.

The composition of *Andronius* trochisces.

Galen in the same place witnesseth, that he hath healed inveterate Vicers and of two yeares old of this kind, with the scales of Iron made into powder, and then boyled in sharpe Vinegar untill it acquired the consistence of Honey: Moreover an Oxes gall dissolved in strong Vinegar, and dropped in warme, amends and dryes up the putrefaction wherewith these Ulcers flow. Also the scales of Iron made into powder boyled in sharpe Vinegar, dried and strewed upon them. But if the straitnesse of the passages should not give leave to the matter contained in the windings of the eares to passe forth, then must it bee drawne out with an Instrument thereupon called a *Pyoulcos*, or matter-drawer, whereof this is the figure.

Scales of Iron,

Of the *Pyoulcos* *Galen* makes mention on 2 ad Glauconem.

The figure of a Pyoulcos, or matter-drawer.

CHAP. XVII.

Of the Vlcers of the Windpipe, weazon, stomacke and Guts.

The Causes.

Hese parts are ulcerated either by an externall cause as an acride medicine, or poyson swallowed downe; or by an internall cause, as a maligne fretting humor which may equall the force of poyson generated in the body, and restrained in these parts. If the paine be encreased by swal-

Signes.

lowing or breathing, it is the signe of an Vlcer in the weazon, or windpipe joyning thereto; But the paine is most sensibly felt when as that which is swallowed is either soure or acride, or the ayre breathed in, is more hot or cold than ordinary. But if the cause of paine lye fastened in the stomacke, more greevous symptomes urge; for sometimes they swound, have a nauseous disposition and vomiting, convulsions, gnawings, and paine almost intollerable, and the coldnesse of the extreame parts; all which when present at once, few scape unlesse such as are young, and have very strong bodyes. The same affect may befall the whole stomacke, but because both for the bitternesse of paine, and greatnesse of danger, that Vlcer is farre more greevous which takes hold of the mouth of the Ventricle, honoured by the Ancients with the name of the heart; therefore Physitions doe not make so great a reckoning of that which happens in the lower part of the stomacke. Now we know that the Guts are ulcerated if Pus, or much purulent matter come forth by stooles; if blood come that way with much griping; for by the Pus staying and as it were gathered together in that place, there is as it were a certaine continuall *Tenesmus*, or desire to goe to stooles.

Gal. lib. 8. de
loc. affect.
cap. 5.

Lib. 4. cap. 5.
Methodo.

The cure.

Now all such Vlcers are cured by meates and drinckes, rather than by medicines, according to *Galen*. Therefore you must make choise of all such meates and drinckes as are gentle, and have a lenitive faculty, shunning acride things; for *Tutia*, Lytharge, Ceruse, Verdigreece and the like, have no place heere, as they have in other Vlcers. But when as the Vlcer shall be in the Gullet or Weazon, you must have a care that such things may have some visciduity or toughnesse, and be swallowed by little, and little, and at diverse times; otherwise they will not much availe, because they cannot make any stay, in these commune wayes of breath and meat; therefore they presently

How to take
medicines for
Vlcers of the
throate.

slip downe and flow away; wherefore all such things shall be used in forme of an *Eglema*, to be taken lying on the backe, and swallowed downe by little and little, opening the muscles of the throate, least the medicine passing downe sodainely and in great quantity, cause a cough, a thing exceeding hurtfull to these kinds of Vlcers. When they must be clenfed, you shall have crude honey, which hath a singular faculty, above all other detergent things, in these kind of Vlcers. But when they can conveniently swallow, you shall mixe Gumme Tragacanth dissolved in some astringent decoction. In Vlcers of the stomacke all acride things (as I have formerly advised) must be shunned, as those which may cause paine, inflammation and vomite, and besides hinder the digestion of the meate. Therefore let them frequently use a pisan, and sugered gellyes wherein Gumme Tragacanth, and bole Armenicke have beene put, the decoction of Prunes, Dates, Figges, Raisons, Honey, Cowes milke boyled with the yoalkes of egges, and a little common honey. When they are to be agglutinated, it will be convenient to make use of austere, astringent, and agglutinative things which want all acrimony, and ungratefull taste, such as are *Hypocistis*, Pomegranate flowres and pills, *terra sigillata*, *sumach*, *acacia*, a decoction of quinces, the Lentiske wood, the tops of Vines, of brambles, myrtles, made in astringent wine, unlesse there be feare of inflammation. Their drinke shall be *Hydromel* water with

Why acride
things must be
shunned in
these Vlcers.

How power-
full Honey is
to cure such
kind of Vlcers:

Sugar, syrupe of Violets and Iujubes. Honey mixed with other medicines is a very fitting remedy for Vlcers of the guts and other parts more remote from the stomacke; for if you shall use astringent medicines alone of themselves, they will sticke to the stomacke; neither will they carry their strength any further; but honey mixed with them, besides that it distributes them to the rest of the body, and helps them forwards to the affected parts; also clenfes the Vlcers themselves. Here also Asses milke may with good successe be used in stead of Goates or Cowes milke. The use

of

of a vulnerary potion is also commendable, if so bee that it bee made of such hearbes and simples, as by a certaine tacite familiarity have respect to the parts affected. But the Vlcers of the Guts have this difference amongst themselves, that if the greater guts be affected, you may heale them with a Glyster and injections, made also sharpe to correct the putrefaction; such as are those which are made of Barly water, or wine with *Ægyptiacum*. But if the small guts be ulcerated, they must bee rather healed by potions and other things taken at the mouth, for that (as *Galen* saith) these things which are put up into the body by the Fundament, doe not commonly ascend to the small or slender guts, but such as are taken at the mouth cannot come unlesse with the losse of their faculty, so farre as the great guts.

Egyptiacum
good for the
Vlcers of the
greater guts.
Lib. 5. meth.

CHAP. XVIII.

Of the Vlcers of the Kidneyes and Bladder.

Vlcers are caused in the Kidneyes and Bladder, either by the use of acride meates, drinkes, or medicines, as *Cantharides*; or else by the collection of an acride humor bred in that place, sent oralne thither; or else by the rupture of some vessell, or an abscess broken and degenerated into an Vlcer, as it sometimes comes to passe. They are discerned by their site, for the paine and heaviness of Vlcers of the Reines comes to the Loynes, and the Pus or matter is evacuated well and thoroughly mixed with the Urine.

Causes.

Signes.

Neither doth the Pus which flowes from the reines stinke so ill, as that which is cast forth of the bladder; the reason is, for that the bladder being a bloodlesse, fleshlesse & membranous part, hath not such power to resist putrefaction. That pus which flowes from the Kidneyes never flowes without water; and although by long keeping in an Urinall, it at length subside or falls to the bottome, and may be seene separated; yet when it is first made, you may see it perfectly mixed with the Urine; but that Pus which flowes from the bladder is oft times made alone without Urine; & usually it comes to passe that the Pus, or matter which flowes from the ulcerated Kidneyes, hath in it certaine caruncles, or as it were haire, according to the rule of *Hippocrates*. Those who in a thicke Urine have little caruncles, and as it were haire come forth together therewith, they come from their Kidneyes; but on the contrarie those who have certaine bran-like scalles come from them in a thicke Urine, their bladder is scabby or troubled with a scabby Vlcer.

*Hip. Aphor. 81**sect. 4.**Aphor. 76.**sect. 4.**Aphor. 77.**sect. 4.*

For the cure, it is expedient that the belly be soluble either by nature or Art, and the use of mollifying Glysters. And it is good to vomit sometimes, so to draw backe the humors by whose conflux into the affected part the Vlcer might bee fed and made more sordide and filthy. You must beware of strong purgations, least the humors being moved and too much agitated, the matter fit to nourish the Vlcer may fall downe upon the Kidneyes or bladder. The ensuing potion is very effectually to mundifie those kind of Vlcers.

The cure.

Why we must
shunne strong
purgos.

R. *Hordei integri*, M. ij. *glycyrrhizæ ras. & contus.* ʒB. *rad. acetosæ & petrosel. an.* ʒvj. *fiat decoctio ad lb. j. in colatura dissolve mellis dispum.* ʒij. R. *quater sem. frig. maj. mundatorum, sem. papaveris albi, sem. malvæ, portul. cydon. baccarum myrti, tragacanth. gum. arab. nucum pincarum mund. pistach. glycyrrhizæ mund. mucaginis sem. psilg, amygd. dulc. hordei mund, an.* ʒij. *bol. armeni, sang. drac. spodi, rosarum, myrrha an.* ʒB. *excipiantur hydromelite, & singantur trochisci singuli ponderis ʒij.* Let him take one thereof in the morning dissolved in Barly water or Goates milke. *Galen* bidsto mixe honey and diurectick things with medicines made for the Vlcers of the Reines and bladder, for that they gently move Urine, and are as vehicles to carry the medicines to the part affected. Vlcers of the bladder are either in the bottome thereof, or at the necke and urinary passage.

Things to
cense these
Vlcers.

Trochisces for
the Vlcers of
the Kidneyes
and bladder.

4. Method.

If they be in the bottome, the paine is almost continuall; if in the necke, the paine then prickes and is most terrible when they make water and presently after. The Vlcer which is in the bottome sends forth certaine scaly or skinny excrements together with the Urine; but that which is in the necke, causes almost a continuall *Tentigo*. Those which are in the bottome are for the most part incurable, both by

Signes to
know what
part of the
bladder is
ulcerated.

The

reason

Why ulcers in
the bottome of
the bladder
are uncurea-
ble.

reason of the bloodlesse and nervous nature of the part, as also for that the Vlcer is continually chased and troubled by the acrimony of the Vrine, so that it can hardly be cicatrized. For even after making of water some reliques of the Vrine alwayes remaine in the bottome of the bladder, which could not therefore passe forth together with the rest of the Vrine, for that for the passing forth of the Vrine, the bladder being distended before, falls and is complicated in its selfe. Vlcers of the bladder are healed with the same medicines as those of the reines are; but these not onely taken by the mouth but also injected by the urinary passage. These injections may be made of *Gordonius* his Trochiscs formerly prescribed, being dissolved in some convenient liquor; but because Vlcers of the bladder cause greater and more sharpe paine than those of the Kidnyes, therefore the Chirurgion must bee more diligent in using Anodynes. For this purpose, I have often by experience found, that the oyle of hen-bane made by expression gives certaine helpe. Hee shall doe the same with Cataplasmes and liniments applyed to the parts about the *Pecten* and all the lower belly and *perinaum*, as also by casting in of Glisters. If that they stinke, it will not be amisse to make injection of a little *Egyptiacum* dissolved in wine, plaintaine or rose water. For I have often used this remedy in such a case with very prosperous successe.

Egyptiacum
for the ulcers
of the bladder.

CHAP. XIX.

Of the Vlcers of the wombe.

The causes.

Vlcers are bred in the wombe either by the confluxe of an acride, or biting humor, fretting the coates thereof, or by a tumor against nature degenerating into an Absesse, or by a difficult and hard labour; they are knowne by paine at the *perinaum*, and the efflux of Pus and Sanies by the privity. All of them in the opinion of *Avicen* are either putride, when as the *Sanies* breaking forth is of a stinking smell, and in colour resembles the water wherein flesh hath beene washed; or else fordide, when as they flow with many virulent and crude humors; or else are eating or spreading Vlcers, when as they cast forth blacke *Sanies*, and have pulsation joyned with much paine. Besides they differ amongst themselves in site, for either they possesse the necke and are known by the sight, by putting in a *speculum*; or else are in the bottome, and are manifested by the condition of the more liquid and ferous excrements, and the site of the paine. They are cured with the same remedies wherewith the ulcers of the mouth to wit, with *aqua fortis*, the oyle of Vitrioll and antimony, and other things made somewhat more milde, and corrected with that moderation, that the ulcerated parts of the wombe may bee safely touched with them; it is requisite that the remedies which are applyed to the Vlcers of the wombe, doe in a moment that which is expected of them, for they cannot long adhere or sticke in the wombe, as neither to the mouth. *Galen* saith that very drying medicines are exceeding fit for the Vlcers of the wombe, that so the putrefaction may be hindred or restrained, whereto this part as being hot and moyst is very subject; besides that the whole body unto this part as unto a sinke sends downe its excrements. If an ulcer take hold of the bottome of the wombe, it shall be cleansed and the part also strengthened by making this following injection. R. *hordei integri* p. ij. *guajaci*. ʒj. *rad. Ireos*. ʒʒ. *absinth. plant. centaury. utriusque*, an. M. j. fiat decoct. in aqua fabrorum ad lb. ij. in quibus dissolve mellis rosati, & *syrupi de absinthio*, an. ʒiij. fiat injectio. For amending the stinking smell I have often had certaine experience of this ensuing remedy. R. *vinirub.* lb. j. *unguent. egyptiaci* ʒij. *bulliant parum*. Thus the putrefaction may be corrected and the painefull maliciousnesse of the humor abated. Vlcers when they are clenfed must presently be cicatrized; that may be done with Alume water, the water of plantaine wherein a little virrioll or Alume have beene dissolved. Lastly, if remedies nothing availing, the Vlcer turne into a Cancer, it must be dressed with anodynes and remedies proper for a Cancer, which you may finde set downe in the proper treatise of Cancers. The cure of Vlcers of the fundament was to bee joyned to the cure of these of the wombe; but I have thought good to referre it to the treatise of *Fistula's*, as I doe the cure of these of the urinary passage to the Treatise of the *Lues venerea*.

CHAP. XX.

Of the Varices and their cure by cutting.

Varix is the dilatation of a Veine, some whiles of one and that a simple branch, otherwhiles of many. Every *Varix* is either strait or crooked, and as it were infolded into certaine windings within its selfe. Many parts of the body are subiect to *Varices*, as the temples, the region of the belly under the Navill, the testicles, wombe, fundament, but

What a *Varix* is and what be the differences thereof.

principally the thighes and legges. The matter of them is usually melancholy blood, for *Varices* often grow in men of a melancholy temper, and which usually feed on grosse meates, or such as breed grosse and melancholy humors. Also women with child, are commonly troubled with them, by reason of the heaping together of their suppressed menstruell evacuation. The precedent causes are a vehement concussion of the body, leaping, running, a painfull journey on foote, a fall, the carrying of a heavy burden, torture or Racking. This kind of disease gives manifest signes thereof by the largenesse, thicknesse, swelling or colour and the Veines.

The matter.

The causes.

Signes.

It is best not to meddle with such as are inveterate, for of such being cured there is to be feared a reflux of the melancholy blood to the noble parts, whence there may be imminent danger of malignant Vlcers, a Cancer, Madnesse or suffocation.

The cure.

When as many *Varices* and diversly implicate are in the legges, they often swell with congealed and dried blood, and cause paine which is increased by going and compression. Such like *Varices* are to be opened by dividing the veine with a Lancet, and then the blood must be pressed out, and evacuated by pressing it upwards and downwards; which I have oft times done, and that with happy successe to the patients, whom I have made to rest for some few dayes, and have applyed convenient medicines. A *Varix* is often cut in the inside of the legge a little below the knee, in which place commonly the originall thereof is seene. He which goes about to intercept a *Varix* downwards from the first originall and as it were fountaine thereof, makes the cure far more difficult. For hence it is divided as it were into many rivulets, all which the Chirurgion is forced to follow.

The cutting of *Varices*

A *Varix* is therefore cut or taken away so to intercept the passage of the blood and humors mixed together therewith, flowing to an Ulcer seated beneath; or else least that by the too great quantitie of blood, the vessell should be broken, and death be occasioned by a hæmorrhagic proceeding from thence. Now this is the manner of cutting it. Let the patient lye upon his backe on a bench or table, then make a ligature upon the legge in two places the distance of some foure fingers each from other, wherein the excision may be made, for so the Veine will swell up and come more in sight, and besides you may also marke it with inke, then taking the skin up betweene your fingers cut it longwayes according as you have marked it, then free the bared veine from the adjacent bodies; and put there under a blunt pointed needle (least you pricke the veine) thred with a strong double thred, and so binde it fast; and then let it be opened with a Lancet, in the middle under the Ligature just as you open a veine, and draw as much therehence as shall be fit. Then straight make a Ligature in the lower part of the forementioned Veine, and then cut away as much of the sayd Veine as is convenient betweene the Ligatures, and so let the ends thereof withdraw themselves into the flesh above and below; let these ligatures alone untill such time as they fall away of themselves. The operation being performed, let an astringent medicine be applyed to the wound and the neighbouring parts; neither must you stirre the wound any more for the space of three dayes. Then doe all other things as are fit to be done to other such affects.

For what intention a *Varix* must be cut.

Paulus cap. 82. lib. 6. The manner how to cut it.

CHAP. XXI.

Of Fistula's.

What a Fistula
is.

Fistula is a sinuous, white, narrow, callous and not seldome unperceivable Vicer. It tooke its denomination from the similitude of a reeden (Fistula) that is, a pipe, like whose hollownes it is. A Fistula is bred in sundry parts of the body, and commonly followes upon Abscesses or Vlcers not well cured.

What a Callousus.

The differences of Fistula's.

The signes.

The signe that the bone is bare from the condition of the matter which is cast forth.

Acrid tetra. 4. fol. 2. cap. 55.

Old Fistula's if closed prove mortall.

A *Callous* is a certaine fleshy substance, white, solid, or dense and hard, dry and without paine, generated by heaping up of dried excrementitious phlegme, or else adust melancholy, encompassing the circuite of the Vicer, and substituting its selfe into the place of laudible flesh. The *Sinus* or cavity of a Fistula is sometimes dry, and otherwhile drops with continuall moisture: sometimes the dropping of the matter sodainly ceases, and the orifice thereof is shut up, that so it may deceive both the Chirurgion and the Patient with a false shew of an absolute cure; for within a while after it will open againe and run as formerly it did. Some Fistula's are bred by the corruption of a bone, others of a nerve, others of membranes, and others of other parts of the body. Some run straight in, others and that the greater part, have turnings and windings; some have one, others have more orifices and windings; some are at the Ioynts, others penetrate into some capacity of the body, as into the chest, belly, guts, womb, bladder; some are easily, others difficultly cured, and some wholly uncurable. There are divers signes of Fistula's according to the variety of the parts they possesse; for if that which you touch with the end of your probe make resistance, and resound, then you may know that it is come to the bone; and then if the end of the probe slip up and downe as on a smooth and polite superficies, it is a signe that the bone is yet sound; but if it stop and stay in any place as in a rough way, then know that the bone is eaten, rough and perished; sometimes the bone lies bare, and then you neede not use the probe. Besides also it is a signe that the bone is affected, if there be a purulent efflux of an unctuous or oily matter, not much unlike that marrow wherewith the bone is nourished. For every excrement shewes the condition of the nourishment of the part whence it is sent; in a Fistula which penetrates to a Nerve, the patient is troubled with a pricking paine, especially when you come to search it with a probe, especially if the matter which flowes dewne be more acrid. Oft times if it be cold, the member is stupified the motion being weakned; besides also the matter which flowes from thence is more subtle, and somewhat like unto that which flowes from the bones, yet not oily nor fat, but sanious and viscous resembling the condition of the alimentary humor of the Nerves. The same usually appeares and happens in Fistula's which penetrate to the Tendons and those membranes which involve the muscles. If the Fistula bee within the flesh, the matter flowing thence is more thicke and plentifull, smooth, white and equall. If it descend into the Veines or Arteries, the same happen as in those of the Nerves; but that there is no such great paine in searching with your probe, nor no offence or impediment in the use of any member: yet if the matter of the Fistulous Vicer be so acrid, as that it corrode the vessells, blood will flow forth; and that more thicke if it be from a veine, but more subtle and with some murmuring if from an Artery. Old Fistula's and such as have run for many yeares, if suddainly shut up, cause death, especially in an ancient and weake body.

CHAP. XXII.

Of the cure of Fistula's.

How to finde out the windings and cavities of Fistula's.

Or the cure; in the first place it wil be expedient to search the Fistula; & that either with a waxe size, a probe of lead, gold or silver, to find out the depth and windings or corners thereof. But if the Fistula be hollowed with two

or

or more orifices, and those cuniculous, so that you cannot possibly and certainly search or finde them all out with your probe; then must you cast an injection into some one of these holes, and so observe the places where it comes forth, for so you may learne how many, and how deepe or superficially cavities there be; then by making incisions you must lay open and cut away the callous parts. You must make incisions with an incision knife or razor, or else apply actuall or potentiall caustics; for nature cannot unlesse the Callous substance bee first taken away, restore or generate flesh or agglutinate the distant bodies. For hard things cannot grow together, unlesse by the interposition of glue, such as is laudible blood; but a callous body on all sides possessing the surface of the ulcerated flesh, hinders the flowing of the blood out of the capillary veines for the restoring of the lost substance and uniting of the disjoyned parts. If you at any time make causticke injections into the Fistula, you must presently stop the orifice thereof, that so they may have time to worke the effect, for which they are intended. Which thing we may conjecture by the tumor of the part, the digesture of the flowing matter, and its lesser quantity. Then you must hasten the falling away of the Eschar, and then the Vlcér must be dressed like other Vlcers. But oft times the Callous which possesses the sinuous cavity of a Fistula, overcome by the power of acrid and escharoticke medicines comes whole forth, and falls out like a pipe, and so leaves a pure Vlcér underneath it. Which I observed in a certaine Gentleman, when I had washed with strong *Agyptiacum* divers times a Fistulous Vlcér in his thigh shot through with a bullet; then presently by putting in my Balsame formerly described, he grew well in a short time. Fistula's which are neare great vessells, Nerves or principall intrailles, must not be medled with, unlesse with great caution. When a Fistula proceeds by the fault of a corrupt bone, it is to be considered whether that fault in your bone be superficially, or deeper in, or whether it is wholly rotten and perished. For if the default be superficially it may easily be taken away with a desquamatory Trepan; but if it penetrate even to the marrow, it must be taken forth with cutting mullets, first having made way with a *Terebellum*. But if the bone be quite rotten and perished, it must bee wholly taken away, which may be fitly done, in the joynts of the fingers, the radius of the Cubite and Legge; but no such thing may be attempted in the socket of the Huckle bone, the head of the Thigh bone, or any of the Rack bones when they are mortified, neither in those Fistula's, which are of their owne nature incurable; but you shall thinke you have discharged your duty and done sufficiently for the Patient, if you leave it with a prognosticke. Of this nature are Fistula's which penetrate even to the bowells, which come into the parts overspread with large vessells or Nerves, which happen to effeminate and tender persons, who had rather dye by much, than to suffer the paine and torment of the operation. Like caution must be used, when by the cutting of a Fistula there is feare of greater danger, as of convulsion if the disease be in a nervous part. In these and the like cases the Chirurgion shall not set upon the perfect cure of the disease, but shall thinke it better to prevent by all meanes possible that the disease by fresh supplies become no worse, which may be done if he prevent the falling downe of any new defluxion into the part; if by an artificiall diet hee have a care that excrementitious humors be not too plentifully generated in the body; or so order it, that being generated they may be evacuated at certaine times, or else diverted from the more noble to the base parts. But in the meane space it shall be requisite to waite the faulty flesh, which growes up more than is fitting in the Vlcér, and to cleanse the *sordes* or filth, with medicines, which may doe it without biting or acrimony and putrefaction.

CHAP. XXIII.

Of the Fistula's in the Fundament.

Fistula's in the Fundament are bred of the same causes as other kinds of Fistula's are; to wit, of a wound or abscesse not well cured, or of a hæmorrhoides which is suppurated. Such as are occult, may be knowne by dropping downe of the *sanious* and purulent humor by the Fundament and the

The causes.

Signes.

the paine of the adjacent parts. But such as are manifest by the helpe of your probe you may finde whither they goe and how farre they reach. For this purpose the Chirurgion shall put his finger into the Fundament of the patient, and then put a Leaden probe into the orifice of the Fistula, which if it come to the finger without interposition of any *medium*, it is a signe it penetrats into the capacity of the Gut. Besides also then there flowes not onely by the fundament but also by the orifice which the maligne humor hath opened by its acrimony, much matter, somewhiles sanious, and oft times also breeding Wormes. Fistula's may be judged cuniculous, and running into many turnings and windings, if the probe doe not enter farre in, and yet notwithstanding more matter flowes thence than reason requires should proceede from so small an Vlcer.

Symptomes.

The art of
binding and
cutting a Fi-
stula of the
Fundament.

You may in the orifices of all Fistula's, perceive a certaine callous wart, which the common Chirurgion steame a Hens arse. Many symptomes accompany Fistula's which are in the Fundament, as a *Tenesmus*, strangury & falling downe of the Fundament. If the Fustula must be cured by manuell operation, let the patient lye so upon his backe, that lifting up his legges, his thighs may presse his belly, then let the Chirurgion, having his naile pared, put his finger belmeared with some oyntment into the patients Fundament, then let him thrust in at the orifice of the Fistula a thick Leaden needle drawing after it a thread consistng of thread and horse haire woven together, and then with his finger taking hold thereof and somewhat crooking it, draw it forth at the Fundament, together with the end of the thread. Then let him knit the two ends of the thread with a draw or loose knot, that so hee may straiten them at his pleasure. But before you bind them you shall draw the thread somewhat roughly towards you as though you meant to saw the flesh therein contained, that you may by this means cut the Fistula without any feare of an Hæmorrhage, or flux of blood.

It sometimes happens that such Fistula's penetrate not into the Gut; so that the finger by interposition of some callous body cannot meete with the needle or probe. Then it is convenient to put in a hollow iron or silver probe so through the cavity thereof to thrust a sharp pointed needle, and that by pricking and cutting may destroy the *callous*; which thing you cannot performe with the formerly described leaden probe, which hath a blunt point, unlesse with great paine.

The description of a hollow Silver probe to be used with a needle,
as also a Leaden probe.

A. Shewes the Needle.

B. The hollow probe.

C. The needle with the probe.

D. The Leaden needle drawing a thread after it.

The *Callus* being waisted, the Fistula shall be bound as wee formerly mentioned That which is superficially needs no binding, onely it must be cut with a crooked *scal- prum*, and the *Callus* being consumed, the rest of the cure must be performed after the

the manner of other Vlcers. But you must note, that if any parcell of the Callous body remaine untoucht by the medicine or instrument, the Fistula reviving againe will cause a relapse.

CHAP. XXIII.

Of Hæmorrhoides.

Hæmorrhoides, as the word is usually taken, are tumors at the extremities of the veines encompassing the Fundament, caused by the defluxion of an humor commonly melancholicke, and representing a certaine kind of *Vari-ces*. Some of these run at an hole being opened, which sometimes in space of time contracts a *Callus*; others onely swell, and cast forth no moisture; some are manifest; others lye onely hidde within. Those which runne, commonly cast forth blood mixed with yellowish serous moisture, which stimulates the blood to breake forth, and by its acrimony opens the mouthes of the veines. But such as do not run, are eyther like blisters, such as happen in burnes, and by practitioners are usually called *vesicales*, and are caused by the defluxion of a phlegmaticke and serous humor; or else represent a Grape, whence they are called *Vvales*, generated by the afflux of blood laudible in qualitie, but overabundant in quantity; or else they expresse the manner of a disease, whence they are termed *morales*, proceeding from the suppression of melancholicke blood; or else they represent warts, whence they are stiled *Verrucæ*, enjoying the same materiall cause of the generation as the *morales* doe.

What they
are.

Their differ-
ences.

This affect is cause of many accidents in men; for the perpetuall efflux of blood extinguisheth the vivide and lively colour of the face, calls on a dropsie, overthrowes the strength of the whole body. The fluxe of Hæmorrhoides is commonly every moneth, sometimes onely foure times in a yeare. Great paine, inflammation, an Abscesse which may at length end in a Fistula, unlesse it be resisted by convenient remedies, doe oft times forerunne the evacuation of the Hæmorrhoides. But if the Hæmorrhoides flow in a moderate quantity, if the patients brooke it well, they ought not to be stayed, for that they free the patients from the feare of imminent evils, as melancholy, leprosie, strangury and the like. Besides, if they bee stopped without a cause, they by their refluxe into the Lungs cause their inflammation, or else breake the vessells thereof, and by flowing to the Liver cause a dropsie by the suffocation of the native heate; they cause a dropsie and universall leanenesse on the contrary, if they flow immoderately, by refrigerating the Liver by losse of too much blood; wherefore when as they flow too immoderately, they must be stayed with a pledget of hares downe dipped in the ensuing medicine. *℞ pul. aloes, thuris, balanst. sang. draconis, an. ʒʒ. incorporentur simul cum ovi albumine, fiat medicamentum ad usum.* When they are stretched out and swolne without bleeding, it is convenient to beate an Onion roasted in the embers with an Oxes gall, and apply this medicine to the swolne places, and renew it every five houres. This kind of remedy is very prevalent for internall Hæmorrhoides; but such as are manifest may be opened with horse-leaches, or a Lancet. The juyce or masse of the hearbe called commonly Dead-nettle or Arkeangell, applyed to the swolne Hæmorrhoides opens them, and makes the congealed blood flow there hence. The *Fungus* and *Thymus* being diseases about the fundament are cured by the same remedy. If acrimony heate and paine doe too cruelly afflict the patient, you must make him enter into a bath, and presently after apply to the ulcers (if any such be) this following remedy. *℞ Olei ros. ʒiiij. ceruse ʒj. Litharg. ʒʒ cera nova, ʒvj. opij ʒj. fiat unguent. secundum artem.* Or else. *℞ thuris, myrrha, croci, an. ʒj. opij ʒj. fiat unguentum cum oleo rosarum & mucagine sem. psij, addendo vitellum unius ovi.* You may easily prosecute the residue of the cure according to the generall rules of Art.

OF BANDAGES, OR, LIGATURES.

THE FOURTEENTH BOOK.

CHAP. I.

Of the differences of Bandages.

Bandages, wherewith we use to binde, doe much differ amongst themselves. But their differences (in Galens opinion) are chiefly drawne from sixe things; to wit, their matter, figure, length, breadth, making, and parts whereof they consist. Now the matter of Bandages is threefold; Membranous or of skinnes, which is accommodated peculiarly to the fractured grilles of the Nose; of Woollen, proper to inflamed parts, as those which have neede of no astringion; of Linnen, as when anie

Lib. de fasciis.

thing is to be fast bound: and of Linnen cloathes, some are made of flaxe, other some of hempe, as Hippocrates observes. But Bandages doe thus differ amongst themselves in structure, for that some thereof consist of that matter which is sufficiently close and strong of it selfe, such are the membranous; others are woven, as the linnen ones. But that Linnen is to bee made choice of for this use, and judged the best, not which is new and never formerly used, but that which hath already beene worne and served for other uses, that so the Bandages made thereof may be the more soft and pliable: yet must they bee of such strength, that they may not breake with stretching, and that they may straitly containe and repell the humour readie to flow downe, and so hinder it from entring the part. These, besides, must not bee hemmed nor stitched, must have no lace nor seame; for hems and seamies by their hardnesse presse into, and hurt the flesh that lyes under them. Lace, whether in the midst or edges of the rowler, makes the Ligature unequall. For the Member where it is touched with the Lace, as that which will not yeeld, is pressed more hard; but with the cloth in the middle more gently, as that which is more lax. Furthermore, these Ligatures must bee of cleane cloth, that if occasion bee, they may bee moystened or steeped in liquour appropriate to the disease, and that they may not corrupt, or make worse that liquour by their moistening therein. Now the Bandages which are made of Linnen cloathes must be cut long-waies, and not athwart, for so they shall keepe more firme and strong that which they binde, and besides, they will be alwaies alike, and not broader in one place than in another. But they thus differ in figure, for that some of them are rowled up, to which nothing must be sowed, for that they ought to be of a due length to binde up the member: others are cut or divided, which truly consist of one piece, but that divided in the end (such are usually taken to bind up the breasts) or else in the midst; others are sowed together, which consist of many branches sowed together, and ending in divers heads, and representing divers figures, such are the Bandages appropriated

Sec. 3. de chir. offic.

What cloth best for rowlers.

to the head. But they thus differ in length, for that some of them are shorter, others longer : so in like sort for breadth ; for some are broader, others narrower. Yet wee cannot certainly define nor set downe neither the length, nor breadth of Rowlers, for that they must be various, according to the different length and thickeſſe of the members or parts. Generally they ought both in length and breadth to fit the parts, whereunto they are used. For these parts require a binding different each from other, the head, the necke, shoulders, armes, breasts, groines, testicles, fundament, hips, thighs, legs, feet and toes. For the parts of Bandages, wee terme one part their bodie, another their heads. By the bodie we mean their due length & breadth, but their ends, whether they run long waies or a-crosse, wee according to Galen, terme them their heads.

CHAP. II.

*Sheweth the indications and generall precepts of fitting of
Bandages and Ligatures.*

1. & 2. ſect.
lib. de fract.

Here are, in Hippocrates opinion, two indications of fitting Bandages or Ligatures ; the one whereof is taken from the part affected ; the other from the affect it ſelfe. From the part affected : ſo the legge, if you at any time binde it up, muſt bee bound long-waies, for if you binde it overthwart, the binding will looſen as ſoone as the patient beginnes to goe, and put forth his legge, for then the muſcles take upon them another figure. On the contrarie the Arme or Elbow muſt be bound up, bending in and turned to the breaſt, for otherwiſe at the firſt bending, if it bee bound when it is ſtretched forth, the Ligature will be ſlacked, for that (as we formerly ſaid) the figure of the muſcles is perverted. Now for this indication, let each one perſwade himſelfe thus much, That the part muſt be bound up in that figure, wherein wee would have it remaine.

We muſt al-
waies begin our
ligatures at the
bottome of a
ſinus.

Hipp. ſent. 4. ſect.
2. offici.

Initio 2. ſect. off.

Now for that indication which is drawne from the diſeaſe, if there be a hollow ulcer, ſinuouſ and cuniculouſ, caſting forth great ſtore of *ſanies*, then muſt you begin the ligature and binding from the bottome of the *ſinus*, and end at the oriſice of the ulcer ; and this precept muſt you alwayes obſerve, whether the *ſinus* be ſealed in the top, bottome, middle, or ſides of the ulcer. For thus the filth therein contained ſhall bee emptied and caſt forth, and the lippes of the ulcer too farre ſeparated, ſhall bee joyned together ; otherwiſe the contained filth will eate into all that lyes neare it, increaſe the ulcer, and make it uncurable by rotting the bones which lye under it with this acride *ſanies* or filth. But ſome Ligatures are remedies of themſelves, as thoſe which perſorme their duties of themſelves, and whereto the cure is committed, as are theſe which reſtore to their native unitie, thoſe parts which are diſ-joyned : others are not uſed for their owne ſakes, but only to ſerve to hold faſt ſuch medicines as have a curative facultie. This kinde of Ligature is eyther yet a doing, and is termed by Hippoc. *Deligatio operans* ; or elſe done and finiſhed, and is called, *Deligatio operata* : for the firſt, that the Ligature may be well made, it is fit that it be cloſe rowled together, and beſides, that the Surgeon hold it ſtiſſe and ſtrait in his hand, and not careleſſy, for ſo he ſhall binde up the member the better. Alſo he muſt in the binding obſerve, that the ends of the Rowler, and conſequently their faſtning may not fall to bee on the affected or grieved part ; for it is better that they come above or below, or elſe on the ſide : beſides alſo, he muſt have a ſpeciall care that there be no knot tyed upon the ſame place, or upon the region of the backe, buttocks, ſides, joynts, or backe part of the head, or to conclude in any other part upon which the Patient uſes to leane, reſt or lye. Alſo on that part where wee intend to ſow or faſten the Rowlers, you muſt double in their ends, that ſo the faſtning or ſuture may be the ſtronger, otherwiſe how cloſe ſoever they ſhall be wrapped or rowled about the member, yet will they not remaine firme, eſpecially if they be of a great breadth. For the ſecond kinde of Ligature, to wit, that which is already done and finiſhed ; the Surgeon, the performer thereof, muſt conſider to what end

it was done, and whether he hath performed it well and fitly, as also neatly and elegantly, to the satisfaction both of himselfe and the beholders. For it is the part of a skilfull Workeman everie where handsomely and rightly to performe that which may so be done.

Ligatures must not bee only lightly, but also neatly performed.

In fractures and luxations & all dislocations of bones, as also in wounds and contusions, you must beginne your bandage with two or three windings or wraps about upon the place, and that (if you can) more straitly than in other places, that so the set bones may be the better kept in their places, and that the humors, if anie be already fallen thither, may by this strait compression be pressed forth, as also to hinder and prevent the entrance in of any other which may bee readie to fall down. But in fractures (as those which never happen without contusion) the blood flowes, and is pressed forth of its proper vessels, as those which are violently battered and torne, which causes sugillation in the neighbouring flesh, which first lookes red, but afterwards black and blue by reason of the corruption of the blood poured forth under the skinne. Wherefore after these first windings, which I formerly mentioned, you must continue your rowling a great way from the broken or luxated part; he which does otherwise, will more and more draw the blood and humors into the affected part, and cause Impostumes, and other malignant accidents. Now the blood which flowes, goes but one way downwards, but that which is pressed is carried as it were in two pathes, to wit, from above downwards, and from below upwards. Yet you must have a care that you rather drive it backe into the body and bowels, than towards the extremities thereof, as being parts which are incapable of so much matter, and not furnished with sufficient strength to suffer that burden, which threatens to fall upon it, without danger and the increase of prenatall accidents. But when this masse and burden of humors is thrust backe into the bodie, it is then ruled and kept from doing harme by the strength and benefit of the faculties remaining in the bowels and the native heat.

fract.

CHAP. III.

Of the three kindes of Bandages necessarie in fractures.

Two sorts of Ligatures are principally necessarie for the Surgeon, according to Hippocrates, by which the bones aswell broken as dislocated may be held firme when they are restored to their naturall place.

Sent. 24. sect. 2.
offic.

Of these some are called *Hypodesmides*, that is, Under-binders: others, *Epidesmi*, that is, Over-binders. There are sometimes but two under-binders used, but more commonly three. The first must first of all bee cast over the fracture, and wrapped there some three or foure times about, then the Surgeon must marke and observe the figure of the fracture; for as that shall be, so must he vary the manner of his binding. For the ligature must be drawne strait upon the side opposite to that whereto the luxation or fracture most inclines, that so the bone which stands forth may be forced into its seat, and so forced may be the more firmly there contained. Therefore if the right side be the more prominent or standing forth, thence must you beginne your ligation, and so draw your ligature to the left side. On the contrary, if the left side be more prominent, beginning there, you shall goe towards the opposite side in binding and rowling it. Here therefore would I require a Surgeon to be *Ambidexter*, (i.e.) having both his hands at command, that so he may the more exquisitly performe such variety of ligations. But let him in rowling, bend or move this first ligature upwards, that is, towards the bodie, for the former reasons. But neyther is this manner of ligation peculiar to fractures, but common to them with luxations: for, into what part soever the luxated bone flew, then when it is restored, that side must be bound the more loosely and gently whence it departed, and that on the contrary more hard unto which it went. Therefore the ligature must be drawne from the side whereunto the bone went; so that on this side it bee more loose and soft, and not straitly pressed with bouldsters or rowlers, that so it

Hypodesmides

may be more inclined to the side opposite to the luxation. If the ligation be otherwise performed, it succeeds not well, for the part is relaxed, and moved out of its naturall seat : wherefore there will be no small danger, lest the bone bee forced out againe, and removed from its place, whereinto it was restored by art and the hand. Which thing Hippocrates so much feared, that on the contrarie he willed that the set bone should be drawne somewhat more unto the part contrary to that whereunto it was driven by force, than the naturall and proper site thereof should require. But to returne to our former discourse of the three Ligatures : The first under-binder being put on, wee then take the second, with which wee in like sort begin at the fracture, but having wrapped it once or twice about there, for that, as we formerly said, wee must not force backe, and presse so much blood towards the extremities, as wee must doe towards the body and bowels. Wherefore this Ligature shall be drawne from above downe-wards, gently straining it to presse forth the blood contained in the wounded part : When by rowling you shall come to the end of that part, then you shall carry back againe that which remains thereof, to wit, upwards ; But otherwise you may take the third under-binder, wherewith you may beginne to rowle, whereas you left with the second, and you may carry it thus, rowling it from below upwards. These under-bindings thus finished, apply your boulders, after them your over or upper bindings, which are oft times two, but sometimes three. The first hath two heads, and is wrapped both from the right hand and the left, for the preservation of the first under-binder and the boulders, and restoring the muscles to their native figure. The two other which remaine, consist of one head, & the one of them must be rowled from below upwards, the other from above downwards, after such a manner, that they may bee directly contrary to the under-binders ; as if they were rowled from the right hand, then these must be from the left. Now this is the manner of Hippocrates his Ligation, which, for that it is now growne out of use, we must here set downe that which is in common use. They doe not at this time use any over-binders, but that which we termed the third under-binder serves our Surgeons in stead of the three forementioned over-binders. Wherefore they carry this third under-binder, wrapped from below upwards (as we formerly said) contrary to the first and second under-binder ; as if these begunne on the right side, this shall be rowled from the left, and shall end whereas the first under-binder ended. And you must not only draw it indifferently hard, but also make the spires and windings more rare. This third rowler is of this use in this manner of Ligation, that is, it restores the muscles to their native figure, from whence they were somewhat altered by the drawing and rowling of the two former Ligatures. But you must alwaies have regard, that you observe that measure in wrapping your Ligatures, which reason, with the sense of the patient, and ease in suffering, prescribes ; having regard that the tumor become not inflamed. Also the habit of the body ought to prescribe a measure in Ligation : for tender bodies cannot away with so hard binding as hard. Verily, in fractures and luxations, the humors by too strait binding are pressed into the extreme parts of the body ; whence grievous and oft times enormous Oedema's proccede : for healing whereof the Ligature must bee loosed, and then the tumified parts pressed by a new rowling, which must bee performed from below upwards, and so, by forcing the matter of the Tumor thither, it may be helped ; for there is no other hope or way to drive the humor backe againe. He which doth this, forsakes the proper cure of the disease, so to resist the symptome, which the Surgeon shall never refuse to doe, as often as any necessarie cause shall require it. For this cause Hippocrates bids, that the Bandages bee loosed everie three dayes, and then to foment the part with hote water, that so the humors, which (drawne thither by the vehemency of paine) have settled in the part, may be dissolved and disperfed, and itching and other such like symptomes prevented. The feare of all accidents being past, let the Ligation bee sooner or later loosed, and more slacked than it formerly was accustomed ; that so the blood and laudible matter, wherof a *Callus* may ensue, may flow more freely to the affected part.

C H A P. IIII.

of the binding up of Fractures associated with a wound.

IT sometimes happens, that a Fracture is associated by a wound, and yet for all this it is fit to binde the part with a Ligature, otherwise there will be no small danger of swelling, inflammation, and other ill accidents, by reason of the too plentiful afflux of humors from the neighbouring parts. But it is not fit to endeavour to use that kinde of binding which is performed with manie circumvolutions or wrappings about. For, seeing the wound must bee dressed everie day, the part must each day necessarily be stirred, and the Ligature, consisting of so many windings, loosed; which thing will cause paine, and consequently hinder the knitting and uniting which is performed by rest. Therefore this kinde of binding may be performed by one onely rowling about the wound, and that with a rowler which consists of a twice or thrice doubled cloth, made in manner of a boulder, and sewed with as much conveniencie as you can, that it may be so large as to encompassse and cover all the wound, for these reasons; which shall bee delivered at large in our Treatise of Fractures. But if the wound runne long-ways, let the boulders and splints be applyed to the sides of the wound, that so the lipps of the wound may bee pressed together, and the contained filth pressed forth. But if it be made over-thwart, we must abstaine from boulders and splints: for that, in Galens opinion, they would dilate the wound, and the purulent matter would be pressed out, and cast back into the wound.

C H A P. V.

Certaine common precepts of the binding up of Fractures and Luxations.

IN everie Fracture and Luxation, the depressed, hollow and extenuated parts, such as are neere unto the joynts, ought to be filled up with boulders, or cloaths put about them, so to make the part equall, that so they may be equally and on every side pressed by the splints, and the bones more firmly contained in their seates. So when the knee is bound up, you must fill the ham or that cavity which is there, that so the ligation may be the better and speedilier performed. The same must be done under the armpits, above the heele, in the arme neer the wrest, and, to conclude, in all other parts which have a conspicuous inequality by reason of some manifest cavities. When you have finished your binding, then enquire of the patient, whether the member seeme not to be bound too strait. For if he say, that he is unable to endure it so hard bound, then must the binding be somewhat slackened. For, too strait binding causes paine, heate, defluxion, a gangrene, and lastly, a sphacell or mortification: but too loose is unprofitable, for that it doth not contain the parts in that state we desire. It is a signe of a just ligation that is neyther too strait nor too loose, if the ensuing day the part be swolne with an oedematous tumor, caused by the blood pressed forth of the broken place; but of too strait ligation, if the part be hard swolne; and of too loose, if it bee no whit swolne, as that which hath pressed no blood out of the affected part. Now if a hard tumor, caused by too strait binding, trouble the patient, it must presently bee loosed, for feare of more grievous symptomes, and the part must be fomented with warme *Hydraeum*, and another indifferent, yea verily, more loose ligation must be made in stead thereof, as long as the paine and inflammation shall continue; in which time and for which cause, you shall lay nothing upon the part which is any thing burdensome. When the patient beginnes to recover, for three or foure dayes space, especially if you find him of a more compact habit and a strong man, the ligation must be kept firme and not loosed. If on the third day, and so untill the seventh, the spires or windings

up.*

Why we must
make more
strait ligation
on the broken
part.

be found more loose, and the part affected more slender; then wee must judge it to be for the better. For hence you may gather, that there is an expression and digestion of the humors, causing the tumor made by force of the ligation. Verily, broken bones fitly bound up, are better set, and more firmly agglutinated, which is the cause, why in the place of the fracture the ligation must bee made the straiter, in other places more loosely. If the fractured bone stand forth in any part, it must there be more straitly pressed with boulders and splints. To conclude, the seventh day being past, we must binde the part more straitly than before: for that then inflammation, paine, and the like accidents, are not to bee feared. But these things which we have hitherto spoken of the three kindes of Ligatures, cannot take place in each fractured part of the body, as in the chaps, collar-bones, head, nose, ribs. For, seeing such parts are not round and long, a Ligature cannot be wrapped about them, as it may on the armes, thighes, and legges, but only bee put on their outsides.

CHAP. VI.

The uses for which Ligatures serve.

The first benefit
of Ligatures.

Y that which wee have formerly delivered, you may understand that Ligatures are of use to restore those things which are separated and moved forth of their places, and joyne together those which gape; as in fractures, wounds, contusions, sinewous ulcers, and other like affects against nature, in which the solution of continuities stands in neede of

The second.

the helpe of Bandages, for the reparation thereof. Besides also, by the helpe of Bandages these things are kept asunder or separated, which otherwise would grow together, against nature; as in Burns, wherein the fingers and the hams would mutually grow together; as also the arme-pits to the chests, the chin to the breast, unless they be hindered by due Ligation. Bandages doe also conduce to refresh emaciated parts: wherefore if the right legge waste for want of nourishment, the left legge, beginning at the foote, may bee conveniently rowled up even to the groine.

The third.

If the right arme consume, binde the left with a strait Ligature, beginning at the hand, and ending at the arme-pit. For thus a great portion of blood from the bound-up part is sent back into the *VENA CAVA*, from whence it regurgitates into the almost emptie vessels of the emaciated part. But I would have the sound part to bee so bound, that thereby it become not painefull; for a dolorifick ligation causes a greater attraction of blood and spirits, as also exercise: wherefore I would have it during that time to bee at rest, and keep holy-day. Ligatures also conduce to the stopping of bleedings: which you may perceive by this, that when you open a veine with your launcet, the blood is presently stayed, laying on a boulder and making a ligature. Also Ligatures are usefull for women presently after their delivery;

The fourth.

The fifth.

for their womb being bound about with Ligatures, the blood wherewith their womb was too much moistened, is expelled, the strength of the expulsive facultie being by this means stirred up to the expulsion thereof: and it also hinders the empty wombe from being swolne up with winde, which otherwise would presently enter thereinto. This same Ligature is a helpe to such as are with childe, for the more easie carrying of their burden; especially those whose Childe lyes so farre down-wards, that lying as it were in the den of the hippe, it hangs betweene the thighes, and so hinders the free going of the mother. Therefore the woman with childe is not only eased by this binding of her wombe with this Ligature, which is commonly termed, the navill Ligature; but also, her childe being held up higher in her wombe, she hath freer and more liberty to walke. Ligatures are in like sort good for revulsion and derivation: as also for holding of medicines which are layd

The sixth.

The seventh.

to a part, as the necke, breast or belly. Lastly, there is a triple use of Ligatures in amputation of members, as armes and legges. The first to draw and hold up-wards the skinned and muscles lying under it, that the operation being performed, they

particular use of
ligatures in the
amputation of
members.

they

they may, by their falling downe againe, cover the ends of the cut-off bones; and so by that meanes helpe forwards the agglutination and cicatrization; and when it is healed up, cause the lame member to move more freely, and with lesse paine; and also to performe the former actions, this, as it were, cushion or boulster of muscous flesh lying thereunder. The second is, they hinder the bleeding by pressing together the veines and arteries. The third is, they by strait binding intercept the free passage of the animall spirits, and so deprive the part which lyes thereunder of the sense of feeling, by making it, as it were, stupid or num.

CHAP. VII.

Of Boulsters or Compresses.

Boulsters have a double use; the first is to fill up the cavities and those parts which are not of an equall thickeesse to their ends. Wee have examples of cavities in the Arme-pits, Clavicles, Hams & Groines; and of parts which grow small towards their ends, in the armes towards the wrists, in the legges towards the feet, in the thighes towards the knees. Therefore you must fill these parts with bouldsters and linnen cloathes, that so they may be all of one bignesse to their ends. The first use of Boulsters.

The second use of bouldsters, is to defend and preserve the first two or three Rowlers or Under-binders, the which we sayd before must be applyed immediately to the fractured part. Boulsters, according to this twofold use, differ amongst themselves, for that when they are used in the first mentioned kind, they must be applied athwart; but when in the latter, long-wayes or down-right. The second use of them.

You may also use Boulsters, lest the too strait binding of the Ligatures cause paine and trouble to the new set bones. A three or foure times doubled cloth will serve for the thickeesse of your Boulsters, but the length and breadth must be more or lesse, according to the condition of the parts and disease for which they must be applyed. The third use of them.

CHAP. VIII.

Of the use of Splints, Junks, and Cafes.

Having delivered the uses of Ligatures and Boulsters, it remaines that wee say somewhat of the other things, which serve to hold the bones in their places; as Splints, Junks, Cafes, and such other like. Splints are made and composed of past bord, of thin splinters of wood, of leather, such as shoo-soales are made with; of the rindes of trees, or plates of Latin, or lead, and such other like, which have a gentle and yeelding stiffe-nesse; yet would I have them made as light as may bee, lest they by their weight become troublesome to the affected part. But for their length, breadth, and number, let them be fitted agreeable to the part whereto they must bee used. Let also their figure be straight or crooked according to the condition of the member whereto they must be applyed. You must have a speciall care, that they runne not so farre as the swellings out, or eminencies of the bones; as the ancles, knees, elbowes, and the like, lest they hurt them by their pressure: also you must have a care, that they be smaller at their ends, and thicker in their middles, whereas they lye upon the broken bone. The use of splints is, to hold fast and firme, that they may stir no way the broken and luxated bones, after they bee set and restored to their places. That they performe this use, it is fit there be no thicke bouldsters under them, nor over many rowlers; for so through so thick a space, they would not so straitly presse the part. Junks are made of stickes the bignesse of ones finger, wrapped about with rushes, and then with linnen cloth: they are principally used in fractures The matter of Splints.
Their use.

for such things.

of the thighes and legges. Cases are made of plates of Latin, or else of some light wood; their use is, to containe the bones in their due figure, when the patient is to be carried out of one bed or chamber into another, or else hath neede to goe to stoole: lastly, if wee must rest somewhat more strongly upon the broken or luxated members, these Cases will hinder the bones from stirring or flying out on the right side or left, above or below, we sleeping or waking, being willing or unwilling, and in like sort lest being not as yet well knit, or more loosely bound up for feare of paine, inflammation, or a gangrene, they hang downe, fall, or fly in sunder by reason of the inequalities of the bed. Such Cases, Junkes, and the like, which serve for restoring and fast holding of broken and luxated bones, we may, according to Hippocrates his minde, call them in generall *Glossocomia*. All which things, the yong Surgeon, which is not as yet exercised in the workes of Art, can scarce tell what they are. But in the meane time, whilst that hee may come to bee exercised therein, or see others performe these operations, I, as plainly as possibly I could, have in words given him their portraiture or shape.

The end of the fourteenth Booke.

OF

OF FRACTURES.

THE FIFTEENTH BOOKE.

CHAP. I.

What a Fracture is, and what the differences thereof are.

Fracture, in Galens opinion, is the solution of continuitie in a bone, which by the Greeks is called *Catagma*. There are many sorts of hurting or offending the bones : as the drawing them a-sunder, luxation, or putting them out of joynt ; their unnaturall growing together, their cutting or dividing a-sunder ; contusion, abscesse, putrefaction, rottennesse, laying bare the *periostium* being violated or lost ; and lastly, that whereof we now treat, a Fracture. Again, the varieties of Fractures are almost infinite. For one is complete and perfect, another imperfect ; one runnes long-wise, another transverse, another oblique ; one while it is broken into great peeces, another while into little and small scales, which have eyther a blunt, or else a sharpe end, and pricke the adjacent bodies of the muscles, nerves, veins or arteries. It somtimes happens, that the bone is not broken into splinters, that is, long-wayes, but together, and at once into two peeces overthwart, which Fracture is called *Raphanedon*, that is, after the maner of a Raddish. Lib. 6. method.

A Fracture is made *Caryedon*, or like a nut, when as the bone flies into many small peeces, severed each from other, as when a Nut is broken with a hammer or mallet upon an Anvile : Which fracture is also termed *Alphitidon*, by reason of the resemblance it hath to meale or floure ; and such is often seene in fractures made by bullets, shot out of guns and such fiery engines. Contrary to these are those fractures which are called *Schidacidon*, as rent into splinters, or after the manner of a boord or peece of timber, that is, right-downe, and alongst the bone : and these fractures are eyther apparent to the eye, or else not apparent, and therefore called *Capillarie*, being so small, as that they cannot be perceived by the eye, unless you put inke upon them, and then shave them with your Scrapers. Sometimes the bone is only pressed downe by the stroke, sometimes on the contrarie it flies up, as if it were vaulted. They call it attrition, when the bone is broken into many small fragments, and as it were scales or chips. The fragments of fractured bones are sometimes smooth and polished, otherwhiles unequall, and as it were sharpe and rough with little teeth, or prickles. Some fractures touch onely the surface of the bone, fetching off only a scale ; other some change not the site of fractured bones, but only cleaves them length-waies, without the plucking away of any fragment ; other some penetrate even to their marrow. What it is for a boneto be broken *Raphanedon*.
What *Caryedon*, or *Alphitidon*.
What *Schidacidon*.

Furthermore some Fractures are simple and alone by themselves ; other some are accompanied with a troop of other affects and symptomes, as a wound, hæmorrhage, inflammation, gangrene, and the like. Hereunto you may also adde the differences

The causes of fractures.

rences drawne from the parts which the Fractures possesse; as from the head, ribs, limbs, joynts, and other members of the bodie. Adde also these which are taken from the habit of bodies, aged, young, full of ill humors, well tempered; almost all which have their proper and peculiar indications for curing. Now the causes of Fractures, are the too violent assaults or stroaks of all externall things, which may cut, bruise, breake, or shake: in this number of causes may also be reckoned fals from high places, and infinite other things, which would be long and tedious to reckon up.

CHAP. II.

Of the signes of a Fracture.

The first signe of a broken bone.

Another.

A third.

WE may know by evident signes that a bone is broken: the first whereof, and most certaine, is, when by handling the part which we suspect to be broken, wee feele peeces of the bone severed asunder, and heare a certaine crackling of these peeces under our hands, caused by the attrition of the shattered bones. Another signe is taken from the impotencie of the part, which chiefly bewrayes its selfe, when both the bones, the legge, and brace-bones, the ell and wand are broken. For if onely the brace-bone or wand be broken, the Patient may goe on his legge, and stirre his arme: for the brace-bone serves for the sustaining of the muscles, and not of the bodie, as the legge bone doth. The third signe is drawne from the figure of the part changed besides nature: for it is there hollow, from whence the bone is flowne or gone, but gibbous or bunching out whither it is runne. Great paine in the interim torments the patient by reason of the wronged *periostium*, and that membrane which involves the marrow and the sympathie of the adjacent parts which are compressed or pricked.

CHAP. III.

Of Prognosticks to be made in Fractures.

Why bones are more brittle in frostie weather.

Why the solution of continuity in bones is not so easily repaired.
Gal. in arte par.

WE must prognosticate in Fractures, whether they are to end in the destruction or welfare of the patient; or whether their cure shall be long or short, easie, or else difficult and dangerous; and lastly, what accidents and symptomes may happen thereupon. Hee shall easily attaine to the knowledge of all these things, who is not onely well seene in the anatomicall description of the bones, but also in the temper, composition and complexion of the whole bodie. Wherefore in the first place, I thinke good to admonish the Surgeon of this, that in winter when all is stiffe with cold, by a little fall, or some such sleight occasion, the bones may be quickly and readily broken. For then the bones, being dried by the drinesse of the ayre encompassing us, become more brittle; which everie one of the Vulgar usually observe to happen both in waxen and tallow candles: but when the season is moist, the bones are also more moist, and therefore more flexible and yeelding to the violence of the obvious and offending bodie. Wherefore also you may gather this to the framing of your Prognosticks, That bones by reason of their naturall drinesse are not so easily agglutinated and consolidated as flesh; though in Children, according to Galen, by reason of the abundance of their humiditie, the lost substance may bee repaired, according (as they terme it) to the first intencion, that is, by restoring of the same kinde of substance or matter. But in others, about the Fractures a certaine hard substance usually concreats, of that nourishment of the broken bone which abounds, which glues together the fragments thereof, being fitly put together. This substance is then termed a *Callus*, and it is so hardened in time, that the bone thereafter in the broken

broken part is seene to be more firme and hard than it is in any other: therefore that usuall saying in Physicke is not without reason; That rest is necessarie for the uniting of broken bones. For the *Callus* is easily dissolved, if they bee moved before their perfect and solid agglutination. The matter of a *Callus* ought to be indifferent and laudible in quantitie and qualitie, even as blood which flowes for the regeneration of the lost flesh in wounds. It is fit, that there may be sufficient matter for such a *Callus*, that the part have a laudible temper, otherwise there either will be no *Callus*, or certainly it wil grow more slowly. Fractures are far more easily repaired in yong bodies than in old: for in these there is plentie of the primigenious and radicall moisture, that is laudably holding and glutinous; and in the other there is store of watrish and excrementitious. By this you may easily conjecture, that you cannot certainly set downe a time necessarie for the generating a *Callus*: for in some it happens later, in some sooner: the cause of which varietie is also to be referred to the constitution of the yeare and region, the temper and diet of the Patient, and manner of Ligation. For, those Patients whose powers are weake, and blood watrish and thin, in these the generation of a *Callus* uses to be more slow: On the contrarie, strong powers hasten to agglutinate the bones, if there be plentie of grosse and viscusous matter; whereby it comesto passe, that meats of grosser nutriment are to be used, and medicines applyed which may helpe forwards the endeavour of nature, as we shall declare hereafter. When the bones are broken neare unto the joynts, the motion afterwards uses to be more difficult, especially if the *Callus*, which is substituted, be somewhat thicke and bunching forth. But if, together with the violence and force of the Fracture, the joynts shall bee broken and bruised, the motion will not only bee lost, but the life brought in danger, by reason of the greatnesse of the inflammation, which usually happens in such affects, and the excesse of paine in a tendinous body. These fractures wherein both the bones of the arme or legge are broken, are more difficult to cure, than those which happen but to one of them. For they are handled & kept in their places with more difficulty, because that which remaines whole, serves the other for a rest or stay to which it may leane. Moreover, there is longer time required to substitute a *Callus* to a great bone, than to a little one. Againe these bones which are more rare and spongie, are sooner glued together by the interposition of a *Callus*, than these which are dense and solid. A *Callus* sooner growes in sanguine, than in cholerick bodies. But broken bones cannot be so happily agglutinated, nor restored in any body, but that alwaies some asperity or unequal protuberancie may bee seene on that part where the *Callus* is generated. Wherefore the Surgeon ought to make artificiall Ligations, that the *Callus* may not stand out too far, nor sinke downe too low. That Fracture is least troublesome which is simple; on the contrarie, that is more troublesome which is made into splinters; but that is most troublesome and worst of all which is in small and sharp fragments, because there is danger of convulsion by pricking a nerve, or the *periostrum*. Sometimes the fragments of a broken bone keep themselves in their due place: they also oft times fly forth thereof, so that one of them gets above another; which when it happens, you may perceive an inequality by the depression of the one part and the bunching forth of the other, as also paine by the pricking: besides also the member is made shorter than it was, and than the sound member on the opposite side is, and more swolne by the contraction of the muscles towards their originall. Wherefore when a bone is broken, if you perceive anie thing so depressed, presently putting your hand on both sides above and below, stretch forth the bone as forcibly as you can; for otherwise, the muscles and nerves, stretched and contracted, will never of their owne accord suffer the bones to be restored to their proper seat and themselves. This extension must bee performed in the first dayes, for afterwards there will happen inflammation: which being present, it is dangerous to draw the nerves and tendons too violently; for hence would ensue an impostume, convulsion, gangrene and mortification. Therefore Hippocrates forbids you to defer such extension untill the third, or fourth day. Fractures are thought dangerous, whose fragments are great, and fly out, especially in these bones which are filled with marrow on the inside. When broken or dislocated bones cannot be

restored

restored to themselves and their naturall place, the part waists for want of nourishment; both for that the naturall site of the veines, arteries and nerves is perverted, as also because the part it selfe lyes immoveable, or scarce moveable: whereby it commeth to passe, that the spirits doe not freely flow thereto, as neyther the nutritive juice commeth thither in sufficient plentie. When the dislocated or broken member is troubled with any great inflammation, it is doubtfull whether or no a convulsion will happen, if wee attempt to restore it, or the parts thereof to their seat: therefore it is better, if it may bee done, to deferre the reducing thereof so long, untill the humor which possesses the part be dissolved, the tumor abated, and the bitteresse of paine mitigated.

CHAP. IV.

The generall cure of broken and dislocated bones.

Three things to be performed in curing broken and dislocated bones.

O cure a broken and dislocated bone, is to restore it to its former figure and site. For the performance whereof, the Surgeon must propose three things to himselfe: The first is, to restore the bone to its place: The second is, that he containe or stay it being so restored: The third is, that he hinder the increase of malignant symptomes and accidents; or else if they doe happen, that then he temper and correct their present malignitie. Such accidents are paine, inflammation, a feaver, abscesse, gangrene and sphacell. For the first intention, you may easily restore a broken or dislocated bone, if presently, as soon as the mischance is got, or else the same day, you endeavour to restore it: for the bitteresse of paine or inflammation, which may trouble the patient, is not as yet verie great, neyther is the contraction of the muscles upwards as yet very much or stubborne. Therefore first of all, the Patient with his whole bodie, but especially with the broken or dislocated part, as also the Surgeon, must bee in some place which hath good and sufficient light. Then let trusty and skilfull attendants be there, good ligatures, and also, if need so require, good engines. His friends which are present, let them see and hold their peace, neyther say, nor do any thing which may hinder the Worke of the Surgeon. Then putting one hand above, that is, towards the center of the body, and the other below, as neare as hee can to the part affected, let him stretch forth the member: for if you lay your hand any distance from the part affected, you wil hurt the sound part by too much compression, neyther will you much avayle your selfe by stretching it at such a distance. But if you only endeavour below with your hand or ligature, assisting to make extension thereof, it will be dangerous if there bee nothing above which may withstand or hold, lest that you draw the whole bodie to you. This being done, according as I have delivered, it is fit the Surgeon make a right or straight extension of the part affected: for when the bone is eyther broken or out of joynt, there is a contraction of the muscles towards their originall, and consequently of the bones by them, as it is observed by Galen. Wherefore it is impossible to restore the bones to their former seat, without the extension of the muscles. But the part being thus extended, the broken bones will sooner and more easily be restored to their former seate. Which being restored, you shall presently with your hand presse it downe, if there be any thing that bunches or stands out. And lastly, you shall binde it up, by applying bouldsters and splints as shall bee fit. But if the bone bee dislocated or forth of joynt, then presently after the extension thereof, it will be requisite to bend it somewhat about, and so to draw it in. The Surgeon is sometimes forced to use engines for this worke, especially if the luxation be inveterate, if the broken or luxated bones be great; and that in strong and rustick bodies, and such as have large joynts: for that then there is need of greater strength, than is in the hand of the Surgeon alone. For, by how much the muscles of the Patient are the stronger, by so much will they bee contracted more powerfully upwards towards their originals. Yet have a care that you extend them not too violently, lest by rending and breaking asunder the muscles and nerves, you cause the forementioned symptomes, paine, convulsion,

How to put the bones in their places.

Hipp. sent. 60. sect. 2. de fract.

Ad sent. 1. sect. 1. de fract.

When instruments or engines are necessary.

vulsion, a palse and gangrene : all which sooner happen to strong and aged bodies, than to children, eunuches, women, youthes, and generally all moist bodies, for that they are lesse hurt by violent extension and pulling, by reason of their native and much humiditie and softnesse. For thus skins of leather, moistened with any liquor, are easily retched and drawn out as one pleaseth: but such as are dry & hard, being lesse tractable, will sooner rend and teare, than stretch further out. Therefore the Surgeon shall use a meane in extending and drawing forth of members, as shall be most agreeable to the habits of the bodies. You may know the bone is set, and the setting performed as is fit, if the paine be asswaged ; to wit, the fibres of the muscles, and the other parts being restored to their former site, and all compression, which the bones moved out of their places have made, being taken away ; if, to your feeling there bee nothing bunching out, nor rugged, but the surface of the member remaine smooth and equall ; and lastly, if the broken or dislocated member compares with its opposite in the compofure of the joynts, as the knees and ancles answer justly and equally in length and thicknesse. For which purpose it must not suffice the Surgeon to view it once, but even as often as he shall dresse it. For it may happen, that the bone which is well set, may by some chance, as by the Patients unconsiderate turning himselfe in his bed, or as it were a convulsive twitching of the members or joynts whilest he sleepe, the muscles of their owne accord contracting themselves towards their originals, that the member may againe fall out ; and it will give manifest signes thereof by renewing the paine, by pressing or pricking the adjacent bodies : which paine will not cease, before it bee restored to its place: and hereof the Surgeon ought to have diligent care. For if, whilest the *Callus* is in growing, one bone ride over another, the bone it selfe will afterwards be so much the shorter, and consequently the whole member ; so that if this error shall happen in a broken legge, the Patient will halt ever after, to his great grieve, and the Surgeons shame. Wherefore the Patient shall take heed, as much as in him lyes, that he stirre not the broken member, before that the *Callus* be hardened. Such diligent care needes not bee had in dislocations. For these once set, and artificially bound up, doe not afterwards so easily fall forth as broken bones.

What bodies are sooner hurt by violent extension.

Signes of a bone well set.

Causes and signes of the relapse of a set bone.

The second scope is, that the bones which shall be restored may bee firmly kept in their state and place. That shall be done by Bandages ; as ligatures, boulders, and other things, whereof hereafter we shall make particular mention. Hither tend proper and fit medicines, to wit, applying of oyle of Roses with the whites of Egges, and the like repelling things ; and then resolving medicines, as the present necessity shall require. It will be convenient, to moisten your rowlers and boulders in oxybate for this purpose, or else in Rose vinegar, if the Fracture be simple, or with red wine, or the like liquor warme (in Galens opinion) if a wound bee joynted to the fracture ; and it will be fit to moisten fractures oftner in Summer: For so the part is strengthened, the defluxion being repelled, whereby the inflammation and paine are hindred. You must desist from humecting and watering the part when the symptoms are past, lest you retard the generating of a *Callus* ; for which you must labour by these meanes which wee shall hereafter declare. To this purpose also conduces the rest and lying of the part in its proper figure and site accustomed in health, that so it may the longer remaine in the same place unstirred. Besides also, it is expedient then only to dresse the part, when it is needfull, & with those things that are requisite, shunning, as much as may be, inflammation and paine. That figure is thought the best, which is the middle, that is, which containes the muscles in their site, which is without paine ; so that the Patient may long endure it without labour or trouble. All these thing being performed, the Patient must be asked, Whether the member be bound up too strait ? If hee answer, No, (unlesse peradventure a little upon the fracture or luxation, for there it is fit it should bee more straitly bound) then may you know that the binding is moderate. And this same first ligation is to bee kept in fractures without loosing for three or foure dayes space, unlesse peradventure paine urge you to the contrary. In dislocations the same binding may bee kept for seven or eight daies, unlesse by chance some symptome may happen, which may force us to open it before that time : for

Ad sent. 21. sect. 1. de fract.

What the middle figure is, and why best.

Fit time for loosing of Ligatures in fractures and dislocations.

the Surgeon must with all his art have a care to prohibite the happening of evill accidents and symptomes, which, how he may bring to passe, shall bee declared in the following Chapter.

CHAP. V.

By what meanes you may performe the third intention in curing fractures and dislocations, which is, the binding and correction of accidents and symptomes.

1. de fract.*

Remedies a-
gainst the itch-
ing.

*Hipp. sent. 46.
sect. 3. de fract.*

That we may attaine unto this third scope, it is requisite we handle as gently and without paine, as we may, the broken or dislocated member; we drive away the defluxion ready to fall downe upon the part by medicines, repelling the humour, and strengthening the part; wee, by appointing a good diet, hinder the begetting of excrements in the bodie, and divert them by purging and phlebotomie. But if these accidents be already present, we must cure them according to the kinde and nature of each of them: for they are various. Amongst which is reckoned itching, which in the beginning torments the Patient: this ariseth from a collection and suppression of subacride vapours, arising from the blood, and other humors under the skin. Whence a light biting, which causeth a simple itch, or else a more grievous and acride one, from whence (in Galens opinion) proceeds a painefull itching. Wherefore such matter, as the cause, being evacuated, all itching ceaseth. But this cannot easily and freely be evacuated and breathed out, because the pores of the part are shut up, and as it were oppressed with the burden of the emplaisters, boulders, and ligatures, which are put about the part. Hereunto may be added, that the part its selfe doth not so perfectly performe and enjoy its wonted faculcies and actions: by which it commeth to passe, that the heat thereof is more languide than may suffice to discusse the fuliginous matter there collected. Wherefore it will be convenient to loose the ligatures everie third day, that, as by loosing their ties, their sanious and fuliginous excrements, shut up under the skinne, may freely passe forth, lest in continuance they should fret and ulcerate it; as it happens to most of those who provide not for it by loosing their ligatures. Besides also, the part must bee long fomented with hote water alone, or else with a decoction of sage, chamomile, roses, and melilote made in wine and water: for long fomenting attenuates and evacuates, but shorter fils and mollifies, as it is delivered by Hippocrates. Also gentle frictions, performed with your hand, or a warme linnen cloath upwards, to the right side and left, and circularly to everie side, are good. But if the skinne be already risen into blisters, they must be cut, lest the matter contained thereunder may corrode and ulcerate the skinne: then must the skinne be annointed with some cooling and drying medicine; as, *Ung. album Camphoratum Rhasis, Desiccativum rubrum, unguentum rosatum sine aceto*; adding thereto the powder of a rotten poste, or prepared Tutia, or the like. Other accidents more grievous than these, doe often happen, but we will treat of them hereafter. But if the scales of the bone underneath bee quite severed from the whole, then must they be presently taken forth, especially if they prick the muscles: But if the bone be broken into splinters, and so prominent out of the wounded flesh as that it cannot be restored into its seat, it must be cut off with your cutting mallets, or parrats beake, as occasion shall offer its selfe. In the interim, you must have a care that the part enjoy perspiration, and by change of place and rising, now and then it may be as it were ventilated: also you must see that it be not over-burdened, neyther too strait bound, otherwise it will be apt to inflammation. Thus much concerning fractures and dislocations in generall: now we must descend to particulars, beginning with a fracture of the Nose.

CHAP. VI.

Of the Fracture of the Nose.

HHe Nose is gristly in its lower part, but bony in the upper. Wherefore it suffers no fracture in the gristly part (unless peradventure a *Sedes*) but only a depression, distortion or contusion. But a fracture often happens to the bony part, & so great a depression to the inner side, that unless it be provided for by diligent restoring it, the nose will become flat, or wrested aside, whence there will be difficulty of breathing. That this kinde of fracture may be restored, that bone which stands too farre out must be pressed downe; but that which is depressed, must be lifted up with a spatherne, or little sticke handsomely fashioned and wrapped about with cotten or a linnen ragge, so to avoyd paine. Therefore you shall hold the spatherne in one hand, and reduce and order it with the other. The bone being restored, directories or tents of a convenient bignesse shall be put into the nose; which tents shall be made of sponge, or flaxe, or a peece of a beasts or sheeps lungs. For these things are soft, and doe not onely hinder the bones of the Nose that they fall no more, but also lift them up higher. And then the Nose shall be in some sort stayed with boulders on each side, even untill the perfect agglutination of the bones, lest the figure and straitnesse should be vitiated and spoyled. I have oft times put golden, silver and leaden pipes into fractured noses, and fastned them with a thred to the Patients night cap, which, by one and the same means, kept the bones from being again depressed, gave the matter free passage forth, and nothing hindred the breathing. In the mean time we must see, that we do not presse the Nose with too strait binding, unless peradventure some other thing perswade; lest they become eyther too wide, too flat, or crooked. If any wound accompany the fracture, that shall be cured after the same manner, as the wounds of the head. The fracture restored, the following medicine, which hath a facultie to repell and repress the defluxion, to strengthen and keep the part in its due posture, and to dry up and waste the matter which hath already fallen downe, shall be applied to the Nose, and all the other dry parts.

Rx. *thuris, mastiches, boli armenia, sanguinis draconis. an. ʒss. aluminis rocha, resina pini. an. ʒij. pulveriscentur subtilissime: Or else, Rx. farina volatilis ʒss. aluminum ovorum quantum sufficit, incorporentur simul, & fiat medicamentum.* A fit astringent and drying medicine.

Neither shall you use any other art to cure the cartilagineous part of the nose being fractured. Wherefore Hippocrates termes that solution of continuitie that there happens, A fracture, as if it were in a bone; because hee could finde no other name more fitly to expresse it: for a gristle, next to a bone, is the hardest of all the parts of our bodie. A *Callus* uses to grow in fractured noses, unless something hinder within the space of twelve or fiftene dayes.

CHAP. VII.

Of the Fracture of the lower Jaw.

HHe lower Jaw runnes into two, as it were, horns or tops: the one whereof ends sharpe, and receives a tendon from the temporall muscle; the other ends blunt and round under the mammillarie prolesse, and it is there implanted in a small cavities; it is joyned together in the middle of the chin by *Symphysis*, and is marrowie within. The Fracture, which happens thereto, is restored by putting your fingers into the Patients mouth, and pressing them on the inside and outside, that so the fractured bones put together may be smoothed and united. But if they be broken wholly athwart, so that the bones lye over each other, extension must be made on both sides on contrary parts, upwards and downwards, whereby the bones may be composed and joy-

may be healed.

ned more easily to one another. The teeth in the meane while, if they be eyther shaken or removed out of their sockets, must be restored to their former places, and tyed with a gold or silver wyar, or else an ordinary threed, to the next firme teeth, untill such time as they shall be fastened, and the bones perfectly knit by a *Callus*. To which purpose the ordered fragments of the fractured bone shall bee stayed, by putting a splint on the outside, made of such leather as shoe soales are made, the midst thereof being divided at the Chin, and of such length and breadth as may serve the Jaw: then you shall make ligation with a ligature two fingers broad, and of such length as shall be sufficient, divided at both the ends, and cut long-waies in the midst thereof; that so it may engirt the chin on both sides. Then there will be foure heads of such a ligature so divided at the ends; the two lower whereof being brought to the crown of the head, shall bee there fastened and sowed to the Patients night-cap. The two upper drawne athwart shall likewise be sowed as artificially as may bee, to the cap in the nappe of the necke. It is a most certaine signe, that the Jaw is restored and well set, if the teeth fastened therein stand in their due ranke and order. The patient shall not lye downe upon his broken jaw, lest the fragments of the bones should againe fall out, and cause a greater defluxion. Unlesse inflammation, or some other grievous symptome, shall happen, it is strengthened with a *Callus* within twentie dayes; for that it is spongius, hollow, and full of marrow, especially in the midst thereof: yet sometimes, it heales more slowly, according as the temper of the patient is, which takes also place in other fractured bones. The agglutinating and repelling medicine, described in the former chapter, shall be used; as also others, as occasion shall offer it selfe. The Patient must be fed with liquid meats, which stand not in need of chewing, untill such time as the *Callus* shall grow hard, lest the scarce or ill-joynd fragments should fly insunder with the labour of chewing. Therefore shall hee bee nourished with water-grewell, ponadoes, cullasses, barley creames, gellies, brothes, reare eggcs, restorative liquors, and other things of the like nature.

CHAP. VIII.

Of the Fracture of the Clavicle or Collar-bone.

Hipp. sem. 63. sect.
I. de art.

How to restore
the fractured
Clavicle.
The first way.

The second
way.

The third way.

As the nature and kinde of the fractured Clavicle shall bee, so must the cure and restoring thereof bee performed. But howsoever this bone shall be broken, alwaies the end fastened to the shoulder and shoulder-blade, is lower than that which is joynd to the chest; for that the arme drawes it downe-wards. The collar-bone, if broken athwart, is more easily restored and healed, than if it be cloven long-waies. For, everie bone broken athwart doth more easily returne into its former state or seat, whiles you lift it up on this or that side with your fingers. But that which is broken *schidacidon*, or into splinters, or long-waies, is more difficultly joynd and united to the ends and fragments: for those peeces, which were set, will be plucked asunder, even by the least motion of the armes; and that which was knit with the shoulder, will fall downe to the lower part of the breast. The reason of which is, the Collar-bone is not moved of its selfe, but consents in motion with the arme. In restoring this or any other fracture, you must have a care that the bones ride not one over another, neyther be drawn nor depart too far in sunder: therefore it will be here convenient, that one servant draw the arme backwards, and another pull the shoulder towards him the contrarie way; for so there will be made, as I may so terme it, a counter-extension. While which is in doing, the Surgeon with his fingers shall restore the fracture, pressing downe that which stood up too high, and lifting up that which is pressed downe too low. Some, that they may more easily restore this kinde of fracture, put a clew of yarne under the Patients arme-pit; so to fill up the cavity thereof: then they forcibly presse the elbow to the ribs, and then force the bone into its former seat. But if it happen, that the ends of the broken bones shall bee so deprest,

depreſt, that they cannot be drawn upwards by the forementioned means: then muſt the Patient be layd with his backe, juſt betweene the ſhoulders, upon a pillow hard ſtuffed, or a tray turned with the bottome upwards, and covered with a rugge or ſome ſuch thing. Then the ſervant ſhall ſo long preſſe downe the Patients ſhoulders with his hands, untill the ends of the bones, lying hid and preſſed downe, ſhew out and ſhew themſelves. Which being done, the Surgeon may eaſily reſtore or ſet the fractured bone. But if the bone be broken ſo into ſplinters that it cannot bee reſtored, and any of the ſplinters pricke and wound the fleſh, and ſo cauſe difficultie of breathing, you then muſt cut the ſkinne even againſt them, and with your inſtrument liſt up all the depreſſed ſplinters, and cut off their ſharp points; ſo to prevent all deadly accidents, which thereupon may bee feared. If there be many fragments, they, after they are ſet, ſhall be covered with a knitting medicine made of wheat flour, frankincenſe, bole armenicke, *sanguis draconis*, *refina pini*, made into powder, and mixed with the whites of egges, putting upon it ſplints, covered with ſoft worne linnen raggs; covered over likewise with the ſame medicine, and then three boulters dipped in the ſame; two whereof ſhall be layd upon the ſides, but the third and thickeſt upon the prominent fracture, ſo to repreſſe it and hold it in. For thus the fragments ſhall not be able to ſtirre or liſt themſelves up further than they ſhould, eyther to the right ſide or left. Now theſe Boulters muſt be of a convenient thickneſſe and breadth, ſufficient to fill up the cavities which are above and below that bone. Then ſhall you make ſit ligation with a rowler, having a double head caſt croſſe-wiſe, of a hands breadth, and ſome two ells and a halfe long, more or leſſe, according to the Patients bodie. Now hee ſhall be ſo rowled up, as it may draw his arme ſomewhat backwards, and in the interim his arme-pits ſhall be filled with boulters, eſpecially that next the broken bone; for ſo the Patient may more eaſily ſuffer the binding. Alſo you ſhall wiſh the Patient, that he of himſelfe bend his arme backwards, and ſet his hand upon his hip, as the Countrey Clownes uſe to doe, when they play at leap-frogge. But how great diligence ſoever you uſe in curing this ſort of fracture, yet can it ſcarce be ſo performed, but that there will ſome deformity remaine in the part: for that a ligature cannot be rowled about the collar-bone, as it may about a legge or an arme. A *Callus* oft times growes on this bone, within the ſpace of twenty daies, becauſe it is rare and ſpongiouſ.

How to binde
up the fractured
clavicle.

vicle,

CHAP. IX.

Of the fracture of the ſhoulder-blade.

 He Greeks call that *Omoſclata*, which the Latines terme *Scapula*, or *Scapula patella*, that is, the ſhoulder-blade. It is faſtened on the backe to the ribs, nowle, the *Vertebra* of the cheſt and necke; but not by articulation, but only by the interpoſition of muſcles, of which wee have ſpoken in our Anatomie. But on the forepart it is articulated after the manner of other bones with the collar-bone, the ſhoulder, or arme-bone: for with its proceſſe, which repreſents a pricke or thorne, and by ſome, for that it is more long and prominent, is called *Acromion*, (that is, as you would ſay, the top or ſpire of the ſaid ſhoulder-blade) it receives the Collar-bone. Therefore ſome Anatomifts, according to Hippocrates as they ſuppoſe, call all this articulation of the Collar-bone with the hollowed proceſſe of the ſhoulder-blade, *Acromion*. There is another proceſſe of the ſaid Blade-bone, called *Cervix omoſclata*, or the necke of the ſhoulder-blade: this truly is very ſhort, but ending in a broad and ſinuuated head, provided for the receiving of the ſhoulder or arme-bone. Not farre from this proceſſe is another, called *Coracoïdes*, for that the end thereof is crooked like a Crowes beake. This keeps the ſhoulder bone in its place, and conduces to the ſtrength of that part. The ſhoulder-blade may be fractured in any part thereof, that is, eyther on the ridge, which runnes like a hill, alongſt the miſt thereof, for its ſafety, as wee ſee in the *Vertebra* of the backe. So alſo in the broader part thereof it may bee thruſt in and

der-blade may
be broken.

depreſt; and alſo in that articulation, whereby the top of the ſhoulder is knit to it. According to this variety of theſe fractured parts, the happening accidents are more grievous or gentle.

The cure.

Lib. de vuln.
Capitis.
A hiftorie.

Nature of its
owne accord
makes it ſelfe
way to caſt
forth ſtrange
bodies and
matters.
Why a fracture
in the joynt of
the ſhoulder
is deadly.

Wee know the ſpine or ridge of the Shoulder-blade to be broken, when a dolorifick inequality is perceived by touching or feeling it. But you may know, that the broader or thinner part thereof is depreſſed, if you feele a cavity, and a pricking paine moleſt the part, and if a numbneſſe trouble the arme, being ſtretched forth. The fragments, if they yet ſtick to their bone, and doe not pricke the fleſh, muſt be reſtored to their ſtate and place, and there kept with agglutinative medicines, and ſuch as generate a *Callus*, as alſo with boulters and rowlers fitted to the place. But if they doe not adhere to the bone, or pricke the fleſh lying under them, then muſt you make incision in the fleſh over againſt them, that ſo you may take them out with your Crowes beake. But although they ſtirre up and downe, yet if they ſtill adhere to the *periosteum* and ligaments, (if ſo be that they trouble not the muſcles by pricking them) then muſt they not bee taken forth: for I have oftner than once obſerved, that they have within ſome ſhort time after growne to the adjacent bones. But if they, being wholly ſeparated, doe not ſo much as adhere to the *periosteum*, then muſt they neceſſarily be plucked away; otherwiſe within ſome ſhort ſpace after, they will be driven forth by the ſtrength of nature, for that they participate not any more in life with the whole. For that which is quicke, ſaith Hippocrates, uſes to expell that which is dead farre from it. The truth whereof was maniſeſt in the Marques of Villars, who at the battell of Dreux was wounded in his ſhoulder with a piſtoll bullet, certaine ſplinters of the broken bone were plucked forth with the peeces of his harnelle, and of the leaden bullet; and within ſome ſhort ſpace after, the wound was cicatrized, and fully and perfectly healed. But more than ſeven yeares after, a deſluxion and inflammation ariſing in that place by reaſon of his labour in armes, and the heavineſſe of his armour at the battell of Mont-contour, the wound broke open againe; ſo that many ſhivers of the bone, with the reſidue of the leaden bullet, came forth of themſelves. But if the fracture ſhall happen in the necke of the ſhoulder blade or dearticulation of the ſhoulder, there is ſcarce any hope of recovery; as I have obſerved in Anthony of Burbon, King of Navarre; Francis of Lorraine, Duke of Guiſe; the Count Rhingrave Philibert, and many other in theſe late civill warrs. For there are many large veſſels about this dearticulation, to wit, the axillary veine and arterie, the nerves ariſing from the *Vertebra* of the necke, which are thence diſſeminated into all the muſcles of the arme. Beſides, alſo inflammation and putrefaction ariſing there are eaſily communicated by reaſon of their neighbour-hood to the heart and other principall parts, whence grievous ſymptomes, and oft times death it ſelfe, enſues.

CHAP. X.

Of the fracture and depreſſion of the Sternum, or Breast-bone.

Signes that the
Sternum is broken.

Signes that it
is depreſt.

The cure.

He *Sternum* is ſometimes broken, otherwiſe onely thruſt in without a fracture. The inequality perceivable by your feeling, ſhews a fracture, as alſo the going in with a thruſt with your finger, and the ſound or noiſe of the bones crackling under your fingers. But a maniſeſt cavity in the part, a cough, ſpitting of blood, and difficultie of breathing by compreſſion of the membrane inveſting the ribs and the lungs, argue the depreſſion thereof. For the reſtoring of this bone, whether broken or depreſt, the patient muſt be layd on his backe, with a cuſhion ſtuffed with tow or hay under the *vertebra* of the backe, as we ſet downe in the ſetting of the Collar-bone. Then a ſervant ſhall lye ſtrongly with both his hands on his ſhoulders, as if he would preſſe them downe, whiſt the Surgeon, in the meane time preſſing the ribs on each ſide, ſhall reſtore and ſet the bone with his hand; and then the formerly deſcribed medicines ſhall bee applyed for to hinder inflammation, and aſſwage paine; boulters ſhall bee fitted thereto, and

and a ligature shall bee made crosse-ways above the shoulders, but that not too strait, lest it hinder the Patients breathing. I by these meanes, at the appointment of Anthony of Burbon King of Navarre, cured Anthony Benand a Knight of the Order, who had his breast-plate bended and driven in, with an iron bullet shot out of a Field-Peece, as also his *sternum* together therewith, and he fell down as dead with the blow; he did spit blood for three months after I had set the bone: yet for all this he lives at this day in perfect health.

A historie.

CHAP. XI.

Of the fracture of the ribs.

THe true ribs, for that they are bonie, may be broken in any part of them. But the bastard ribs cannot be truly broken unlesse at the backe bone, because they are onely bonie in that part, but gristly on the foreside towards the breast-bone, wherefore there they can only be folded or crooked in. These which are subject to fractures, may be broken inwards and outwards. But oft times it comes to passe, that they are not absolutely broken, but cleft into splinters, and that sometimes inwards, but not outwards. Thus the fissure doth oft-times not exceede the middle substance of the rib; but sometimes it so breakes through it all, that the fragments and splinters do prick and wound the membrane, which invests and lines them on the inside, and then there is great danger. But when the fracture is simple without a wound, compression, puncture of the membrane, and lastly, without any other symptome, then the danger is lesse. Therefore Hippocrates wisheth, that these, who are thus affected, fill themselves more freely with meat; for that moderate repletion of the belly, is (as it were) a certaine prop or stay for the ribs, keeping them well in their place and state: which rule chiefly takes place in fractures of the bastard ribs. For such as have them broken, usually feele themselves better after, than before meat. For emptinesse of meat, or of the stomach, makes a suspension of the ribs, as not underpropped by the meat. Now that fracture which is outwardly, is farre more easie to heale, than that which is inwardly; for that this pricketh the membrane or *Pleura*, and causeth inflammation, which may easily end in an *Empyema*. Adde hereunto, that this is not so easily to be handled or dealt withall, as the other: whereby it commeth to passe, that it cannot be so easily restored; for that these things cannot bee so fully and freely performed in this kinde of fracture, which are necessary to the setting of the bone, as to draw it out, hold it and joine it together. It is therefore healed within twenty dayes, if nothing else hinder. The signes of fractured ribs are not obscure; for by feeling the grieved part with your fingers, you may easily perceive the fracture by the inequalitye of the bones, and their noyse or crackling, especially, if they bee quite broke asunder. But if a rib be broken on the inside, a pricking paine, far more grievous than in a *Pleurisie*, troubles the Patient; because the sharp splinters pricke the *Costall* membrane: whence great difficulty in breathing, a cough and spitting of blood ensue. For blood, flowing from the vessels broken by the violence of the thing causing the fracture, is (as it were) sucked up by the lungs, and so by a dry cough carried into the weazond, and at length spit out of the mouth. Some, to pull up the bone that is quite broken and deprest, apply a cupping glasse, and that is ill done: for there is caused greater attraction of humors, and excesse of paine by the pressure and contraction of the adjacent parts, by the cupping-glasse; wherefore Hippocrates also forbids it. Therefore it is better to endeavour to restore it after this following manner. Let the Patient lye upon his sound side, and let there be layd upon the fractured side an emplaister made of Turpentine, rosin, black pitch, wheat floure, mastick and aloes, and spread upon a strong and new cloath. When it hath sticke there some time, then plucke it suddenly with great violence from below upwards: for so the rib will follow together therewith, and bee plucked and drawne upwards. It is not sufficient to have done this once, but you must

must

A simple fracture may be cured onely by Surgerie.

must doe it often, untill such time as the Patient shall finde himselfe better, and to breathe more easily. There will be much more hope of restitution, if, whilst the Surgeon doe this diligently, the Patient forbear coughing, and hold his breath. Otherwise, if necessitie urge, as if sharpe splinters with most bitter tormenting paine pricke the Costall membrane overspred with many nerves, veines, and arteries, which run under the ribs, whence difficultie of breathing, spitting of blood, a cough and fever ensue; then the only way to deliver the Patient from danger of imminent death, is, to make incision on the part, where the rib is broken, that so laying it bare, you may discerne the pricking fragments, and take them out with your instrument, or else cut them off. And if you make a great wound by incision, then shall you sew it up, and cure it according to the common rules of curing wounds. Now Diet, Phlebotomie and Purgation, which (as Hippocrates saith) are not very needfull in a simple fracture, for that there are no symptomes, which may require such remedies; yet, they, by reason of the complicated symptomes, as a convulsion, feaver, *Empyema*, and the like, must here be prescribed, by the advice of the Physician which oversees the cure. A Cerate, and other remedies fitting the occasion, shall be applyed to the grieved part: no other ligatures can be used, than such as are fit to hold fast and stay the locall medicines. There is no other rule of site and lying, than such as is taken from the will and content of the Patient.

CHAP. XII.

Of certaine preternaturall affects which ensue upon broken ribs.

Any symptomes ensue upon fractured and contused ribs: but amongst the rest, there are two which are not common, whereof we will treat in this place. The first is, the inflation, or rising up of the contused flesh, which also ensues upon light affects of the bone, which have bin neglected at the beginning. But the flesh is not meerly puffed up of its selfe, but also with a certaine phlegmatick, glutinous and viscous humour gathering thereinto. The cause hereof is, the weaknesse of the digestive facultie of the part, occasioned by the stroake and distemper; which therefore cannot assimilate the nourishment flowing more plentifully than it was wont, eyther drawne thither by means of the pain, or sent thither by a blinde violence of nature, stirred thereto by a desire of its own preservation. Wherefore this halfe crude humor remaining there, raiseth much flatuling from its selfe, or else wrought upon by the weaker heat, it is resolved into cloudy vapours; whence it commeth to passe, that the flesh is swolne up in that place, and the skinne on the contrary growes soft, as if it were blowne up with a quill. Therefore laying your hand thereon, you may heare the noyse of the winde going forth thereof, and see a cavity left in the part, as it is usually seene in oedematous tumors. Unlesse you remedie this inflation, there will ensue an inflammation, fever, abscesse, difficulty of breathing; and lastly, that second kinde of affect, whereof we have determined to treat in this Chapter, to wit, the putrefaction, corruption, or blasting of the ribs. An abscesse, and the separation of the flesh from the bone, is the cause hereof: for hence it commeth to passe, that the bone, despoyled of its naturall and fleshly cloathing wherewith it was cherished, is easily offended by the touch of the entring ayre, which it never formerly felt, and so at length it becommeth (as it were) blasted: which when it happens, they spit up filth, and so fall into a consumption, and at length dye. To withstand all these inconveniencies, you must, as speedily as you can, restore the fractured bones by the formerly delivered meanes. And then this mucous tumor must be resolved by proper heating and discussing medicines, and kept downe by boulders and rowlers, that so the flesh may touch the bone, and cover it as it usually did. But the ligature shall not be made so strait, as to hinder the ribs from their wonted motion in expiration and inspiration. If the tumor degenerate into an Abscesse, it shalbe speedily opened,

lest the matter, kept in too long, corrupt the bone which lyes under it, by the contagion of its putrefaction. The Ulcer being opened, the matter shall bee evacuated by putting a pipe into the ulcer; the end whereof shalbe bound about with a thred, lest it fall into the capacity of the chest, and that it may bee drawne forth at your pleasure.

C H A P. XIII.

*Of the fracture of the Vertebra, or Rack bones of the backe,
and of their processes.*

THe *Vertebra* are some-whiles broken, otherwhiles bruised, or strained on the inside, wherby it commeth to passe, that the membranes which invest the spinall marrow, as also the spinall marrow its selfe, are compressed and straitened, which cause many maligne accidents; which, whether they be curable or not, may be certainly foretold by their magnitude. Amongst these symptomes, are the stupidity, or numnesse and palsie of the armes, legges, fundament and bladder, which diminish, or else take away from them the facultie of sense and motion; so that their urine and excrements come from them against their wils and knowledge, or else are wholly supprest. Which when they happen (saith Hippocrates) you may fore-tell that death is at hand, by reason that the spinall marrow is hurt. Having made such a prognosticke, you may make an incision, so to take forth the splinters of the broken *vertebra*, which, driven in, presse the spinall marrow, and the nerves thereof. If you cannot doe this, at least you shall apply such medicines as may assuage paine, and hinder inflammation; and then the broken bones shall be restored to their places, and contained therein by those meanes which we shall mention when we come to treat of the luxation of the spine. But if that the processes onely of the *vertebra* be broken, the fragments shall be put in their places, unlesse they bee quite severed from their *periostium*. But if they bee severed, you shall open the skinne and take them forth, and then dresse the wound as is fit. Wee understand, that onely the processes of the *vertebra* are broken, if, in the absence of the fore-mentioned symptomes of numnes and the palsy, you, laying your finger upon the grieved part, feele something, as a bony fragment, shaking and moving thereunder, with a certaine crackling noyse, and cavitic, and depression; and then, if when the Patient holds downe his head, and bends his backe, hee feele farre more paine, than when hee stands up straight on his feete. For in stooping, the skinne of the backe is somewhat stretched forth, and extended, and also forced upon the sharpe Splinters of the fragments, whence proceedes a dolorifick solution of continuitie, and a pricking: in standing straight up, on the contrary, the stretched skinne is relaxed, and consequently lesse molested by the sharpe fragments. The fractured processes of the *vertebra* easily heale, unlesse they bee associated with some other more grievous symptome which may hinder; such as is a certaine great contusion, and the like. For, as wee formerly sayd out of Hippocrates, All rare and spongie bones are knit by a *Callus* within a few dayes.

Of the fracture of the holy-bone.

What fracture
of the Holy-
bone curable
and what not.

Also the Holy-bone in a certaine part thereof, which may be easily healed, may be broken by the blow of bruising things, as by a bullet shot out of a musket, as I have observed in many. But if the fracture violate, together with the *vertebra* thereof, the spinall marrow contained therein, then the Patient can scarce scape death, for the reasons shewed in the former Chapter.
